Since writing the above I have seen "A WEST YORKSHIREMAN'S" letter. He evidently had his birds from Mr. Crossland, as to whose breed I have already spoken. I do not think £1 each for the birds taken altogether was a high price, and certainly no indication that they were all very good. I have sold many birds this season at two and three guineas each which were anything but good—that is to say, what I understand by good. The fact is, that if "A WEST YORKSHIREMAN'S" birds were all good—i.e., first-rate, the cocks were worth from £10 to £20 and the pullets from £3 to £5 each, and Mr. Crossland himself must have sold them considerably under their value. I will now conclude by again asking with "GALLUS," How is it that good birds fetch such prices if they are so easily bred? How is it that Mr. Hawkesley refuses £20 for his bird? I mention him, as he is no novice at breeding Game Bantams, and, of course, if they are easily bred, he has plenty more as good. How is it I refused £15 for a bird I bred last year? How is it that Sir St. George Gore recently gave Mr. Crossland £10 for a pair of pullets? I want some more definite answer to these questions than a reference to the tulip mania, which is not in point. Again I ask, How is it that the gentlemen who found Game Bantams so easy to breed good do not sweep off all the prizes? How is it that so few really good birds are shown—so few, in short, are in existence? The first-class cockerels of the year 1865 may be counted on the fingers: how is that, if they are so easily bred? And as to pullets, it will astonish those who can breed them so easily to learn that, though I began to inquire before the Birmingham Show for some first-class pullets, I have been unable up to this day to obtain them, though I would willingly give £10 for a pair; and yet, notwithstanding these facts, Game Bantams are easy to breed!—P.

Not knowing the address of the "WILTSHIRE RECTOR," I cannot directly compliment him for the stand he has so firmly made, and held so well, about my pets, Game Bantams; and so clearly has he spoken the sentiments of my mind as to their being easy to breed, that I could almost fancy, whilst reading his communications, that he was looking over my notes on their breeding, and then strolling amongst my stock. Your correspondents, "GALLUS," and "W. F. E.," seem to think, as our "WILTSHIRE RECTOR" has parted with his Game Bantams, and not continued to be an exhibitor of them, that he only holds his ground. They are dreadfully mistaken, and if stock is gone, there is more than one yard left that contains birds that breed both good and true; and if "GALLUS," "W. F. E.," "WILTSHIRE RECTOR," or any other fancier of Game Bantams, wishes to prove whether they are easy to breed good, then I say here is evidence, for I have bred Game Bantams for eight years, and so closely have I given the Black Reds my attention, that very rarely indeed have I attempted to rear any other class of birds, and, perhaps, not so many of these as I ought. However, I have exhibited rather more than sixty pens of Black Red Game Bantams in my own name, and that of Mr. George Noble, and have won upwards of fifty prizes, and only on eight or nine occasions have my birds been shown without either obtaining a first, second, or third prize. Again, last year (1865), I bred seventeen cockerels and nine pullets, and I realised upwards of £50 for fourteen

cockerels out of this number, and for two pullets besides. I fancy I kept the best for myself.

Again, I do not consider that my cockerels are anything so near perfection as my pullets are; and if I may be allowed, I will construe the words of "GALLUS" into "very good," in place of "certainly not have written," and I must say after that, that I believe the rest of the sentence, "they are easy to breed good;" at least I have the opinion of some of the best breeders and dealers, that they have not seen any pullets to beat, if equal, mine.

Now, as to breeding one good bird in a hatch, why, such words make my shoulders almost touch my ears, as they recall to my recollection how I stood in the Bantam category about three years ago. I can fancy the stock of "GALLUS," and "W. F. E.," and how angry I feel just now, and I suppose they do the same, as most likely our positions were somewhat similar. Only last year a certain Yorkshire fancier, Mr. W. F. Entwistle, of Odley (perhaps the "W. F. E."), told me he had bred and killed upwards of seven hundred birds as worthless. When I write of my ill-luck of three years ago, I am reminded that I then had a fancy that a cross would be beneficial, consequently I gave £3 3s. for a pen, and their produce and stock, with the exception of one hen, I killed. She was good-looking; and a friend of mine, Mr. R. Smith, of Hull, was in love with her, and even offered me £5 for her. However, I lent her to him, and the result was similar to that which occurred in my own case. Whites, Blacks, Browns, Grey, Spangled, and even piebald Blacks and Whites, were the colours they bred me; but now, before mine are hatched, I can tell any one pretty nearly what they will be, and if I were to have one photographed, I could safely say that nine out of every ten would be the exact *fac-simile*. If "GALLUS," "W. F. E.," or "WILTSHIRE RECTOR" in particular, give me a call at any time, I will make him as comfortable amongst Bantams as he seems to be amongst his own fowls, if looking at a few choice birds will do so; and if his visit be delayed for a short time, he will see rather more, as my breeding stock is showing fruit. I will pay his expenses of coming, if he is afraid of being again disappointed in the colour, head, neck, legs, or style in particular, and I say my birds will not disappoint him. Like my fellow fancier, Mr. Crossland, I do not believe in crossing with any one's strain to such an extent as some people would lead us to believe is the proper method.

Here is the history of my strain. In the first year I picked up in the country for a mere trifle a cock Black Red Bantam, and a hen not related to him. I bred from the two, and some little improvement was the result of this cross. Next year I crossed with the cock the pullets that were bred from him, again I found some improvement, and for the following year I obtained a Duckwing cockerel from Mr. Crossland's yard. From this date my strides began to be more rapid, until I introduced another strain, then I was placed *hors de combat*; but such reliance did I place in my old stock, that I felt more success would attend my efforts another year, and I crossed with birds from the yard of Mr. Smith, of Hull, he having kindly lent me his old cock and four hens. This was the greatest hit I ever had in my Game Bantam breeding. I have not introduced any fresh strain these two years, and do not intend to do so, my fear is not half so much in not breeding quality as quantity. Mr. E. Hewitt, of Sparkbrook, saw my birds last September, and he will, perhaps, tell you what they were, as most likely he will have some faint recollection about their evenness in quality, although not so many in number.

By-the-by, here is an instance which, perhaps, may in some measure illustrate the case. At Keigley Show last year, Mr. Hewitt was judge, and he was somewhat puzzled betwixt two pens in the Black Red Game Bantam class, as to which to award the first and second prizes to, so much so that he had them taken from their positions and placed in two pens close to each other, so that he might be the better enabled to make his award satisfactorily, and when he had so done—both pens had left my yard not many hours before—the first-prize pen was mine, the second I had sold two days previously, and Keigley was the appointed place of transfer. Not so very uneven, "WILTSHIRE RECTOR," when I bred then less than thirty birds altogether, and one of the best judges was thus driven to this extremity.

Two more instances and I have done. First, Mr. Smith's strain, if I mistake not, has sprung from the brother to the bird on which Mr. Crossland lays his foundation. The other is: I was a breeder of Game Bantams for four years, with the advice of an old exhibitor and careful Game breeder for ten

years previously, Mr. Noble, before I threw down the gauntlet and became an exhibitor, and my first essay was in a class of upwards of forty pens, and I came off with success, which duly gratified me for my past exertions, and stimulated me to increase my care of these little pets, which I, with "WILSON'S RECTOR," and scores more, say are easy to breed, but still all feel sorry we cannot have the best.—Jno. D. NEWSOME.

STEALING FOWLS AT EXHIBITIONS.

CHARLES LISTER, of Mirfield, a man respectably connected, was committed on the 5th inst., by the sitting magistrates at Dewsbury, to the House of Correction, for stealing a Black Bantam cock, the property of Mr. Matthew Ridgway, of that town.

On the 26th of December last there was a poultry show at Heckmondwike, and Mr. Ridgway, through a man of his named Williamson, was an exhibitor. He took the second prize for Bantams in one of the classes with this bird, and after the show was over Williamson placed it in a room in the inn where the exhibition was held, intending to remove it when he was ready for going home. In a short time he went to look for the Bantam, but it was gone, and, though a strict search was made (the prisoner assisting), nothing was heard of it until a few days ago, when, by a little stratagem, it was traced to the prisoner's possession by Police Sergeant Lee, and it was ascertained that he had sent it to Hull to a dealer there, on approval, the price he set on the bird being £5. Witnesses were called who identified the Bantam produced by the police sergeant as the one stolen, and it was valued at the sum asked for it by the prisoner. Lister, when before the Bench, pleaded guilty. He said he took the bird more for fun than anything else, not being sober at the time; that he was afraid to return it; and that had he disposed of it to the Hull dealer for the sum he asked he should have sent the money in an anonymous letter to Mr. Ridgway. Another case of fowl stealing came before the Bench—indeed, there were three instances where theft was proved. The delinquent was James Ruddesden, and it was deposed that he had robbed hen-roosts at Earlsheaton. The prisoner was committed for trial to the sessions.—(*Leeds Mercury*.)

[We rejoice that one villain has been caught; and his published conviction, like a gibbeted felon, we hope will serve as a warning to other thieves "respectably connected." The gentleman who sent us the above report adds—"Mr. Ridgway has done well in trying to put a stop to fowl-stealing and mutilation, which are now so common at poultry exhibitions. I believe Mr. Ridgway would not have pressed the case, but it was not the first offence. The presiding magistrate, Mr. Greenwood, sentenced Lister to three months imprisonment with hard labour."]

CITY BEE-KEEPING IN AMERICA.

PROBABLY some of your readers may be interested in the experience of a city bee-keeper. If you think so I will, with your permission, introduce them to the apiary of an amateur in the City of Philadelphia.

PASTURE.—First let me describe the situation. For city bees mine are favourably placed, having around them more than an acre devoted to trees, shrubbery, and grass; besides which, many of our neighbours have small yards planted with shrubs and flowers; but the closely-built city extends in all directions around us. To the eastward, at the distance of three-quarters of a mile, flows the river Delaware, which has about that breadth. To our west is the Schuylkill, a much narrower stream, but at a greater distance; so that in either of these directions bees must fly more than a mile and a half before reaching partially open country. Southward, a flight of a mile and a quarter takes them to commons and vegetable gardens. To look northward is hopeless; more than three miles of brick and mortar might well dishearten any bee.

One advantage my bees have over those in England is a generally clear atmosphere, our common fuel being anthracite coal, which burns without smoke.

LIGURIAN BEES.—One of my colonies, occupying the double-storey Langstroth-hive, figured in that gentleman's book as a "moveable comb-hive with full glass arrangement," was Ligurianised in the autumn of 1863. The following year was not a very good one for honey, and I did not obtain much from any of my hives. This stock would probably, however, have

done better than it did, had I not neglected to furnish supers until all the available space below was so filled that there was scarcely room for the bees to pass up to them. The result was quite a moderate yield—not more than about 25 lbs. in the supers. I did not then remove any honey from the main hive, as I wished to leave an ample supply for the winter.

In April, 1865, this hive was examined by an expert, who assured me it had so much honey that there was insufficient room for brood. I therefore had three frames removed, with honey weighing about 20 lbs. Some weeks afterwards I took out yet another frame of honey and brood to replace a drone-breeding queen in another hive, an operation which proved successful.

The bees then entered upon their summer's work, to facilitate which, and to avoid the error of the preceding year, I took a super of the same dimensions as the hive proper, furnished with a full set of frames, and, first removing the crown or honey board, placed this super directly upon the hive. The bees entirely filled it with fine honey, which I removed on the 6th of October, and found to weigh 83 lbs. nett. I also took, a few days later, combs weighing 15 lbs. from the main hive, leaving still an ample store for the winter. In addition to these 98 lbs., I had taken, as before stated, at least 25 lbs. from the same hive in the spring, most of which, however, was gathered in the previous year. Still this stock of Italian bees has yielded me this season upwards of 100 lbs. of honey; while black bees, having the same range, have never given me much more than half the quantity.

The industry of the Ligurians is very remarkable. As an example of it, I may state that the three frames from which honey was taken having been returned to the hive, the bees, although so late in the season, at once set to work to repair damages, and have actually filled up two-thirds of these frames with new comb, and even deposited honey in a portion of it.

SUPERS AND COLLATERAL BOXES.—So far all my experience has tended one way, and that in favour of ample supers. The smaller and more numerous the supers, whether tumbler, bell-glass, or box, the less has been the surplus honey; and my success has been least of all when trying to induce bees to travel laterally. I believe it to be about as unnatural for bees to work in collateral boxes as for hot air from a furnace to travel horizontally. You may force either, but it is not economical to do so.

Mr. Langstroth tells me that I erred in removing the crown or honey board before placing the super, as it rendered the deposit of brood in the upper box more probable. He recommends leaving this division of the hive, but with ample cuts in it for the passage of the workers. He also advises simple bars, instead of frames, for these large supers; coinciding in this, I believe, with your "DEVONSHIRE BEE-KEEPER."

WINTERING BEES.—Our winter climate is a very variable one. A difference of 20° or more Fahrenheit in as many hours is by no means unusual, nor unaccompanied by corresponding hygro-metric changes. In this climate my hives, wooden boxes of Langstroth's design, have been freely exposed, without the least protection. For winter ventilation I have merely removed the supers, leaving the passages in the crown board uncovered, giving both the air and the bees free access to the upper part of the hive, and have found this a sufficient winter ventilation.

I have, however, this season, at the recommendation of Mr. Langstroth, removed the crown-boards from the hives, and placed pieces of old blanket directly upon the frames. This I think will improve the ventilation, dryness, and general condition of the hives, although I do not think that my bees have ever seriously suffered from dampness, while numbers have occasionally perished from the low temperature upon the outer combs, when no winter passage has been left or made through these. This passage should always be made in the autumn. It is easily done by passing the blade of a knife vertically through the middle of the comb on each frame. If this is done late in the season the mutilated cells will be cleared away by the bees but not rebuilt, and they will then have the means of rapidly retreating to the central part of the hive; while without this passage they might be chilled and die upon the outer combs.

COMPARATIVE LONGEVITY OF THE LIGURIAN AND BLACK BEE.—On the 7th of June, 1862, I introduced a Ligurian queen into a strong colony of black bees. She was courteously received, and laid some eggs, but afterwards was probably killed by a rival raised from the larva of her predecessor; as your old acquaintance Mr. H. C. Hermann, author of "The Italian Alp Bee," examined the hive about a month after her introduction, and assured me she was missing.

I observe that Mr. Neighbour, in his late book, reports the

death of Mr. Hermann. Allow me to assure him the report is erroneous: Hermann still lives and is working among bees. For several years he kept a cigar shop in a suburb of Philadelphia, and attended to the bees of amateur apiarians. One of my neighbours sent him to Europe for Ligurians. He secured many stocks, but had a long return passage and lost every bee. In the spring of the present year he removed to the country, hoping to improve his fortunes by going more largely into bee-keeping than he could do in the city.

To return to the bees. I very soon found the progeny of the Ligurian queen among the workers, and hoped also to find Hermann mistaken. Next spring, however, the number of Italians was stationary, and all the young bees were black. I frequently watched the return of the workers, counting them to ascertain the proportion of Italians, and arrived at the conclusion that they were about the thirtieth of the working population of the hive. About the 16th of July, 1863, I obtained another Ligurian queen, which was introduced by Mr. Hermann. She was well received, and six weeks afterwards I found her progeny very numerous. The number of black workers rapidly decreased. All the drones were killed; and long before winter there were no black bees left in the hive.

Thinking this rapid disappearance extraordinary, I wrote to Mr. Langstroth, asking him if my black bees had not been destroyed by the foreigners. My friend replied that the Italians were doubtless innocent of apicide; but added, "the life of a bee in the working season is very short." As regards the black bee this is strictly true; but experience satisfies me that the Italians are hardier and live longer than their black brethren, the progeny of the first Ligurian queen having maintained their position in this hive for nearly twelve months, in numbers lessening with time, it is true, but by no means rapidly; while in less than one-fourth of that time every black bee perished.

—W. G. MALIN, Philadelphia, U.S.

TICKLENESS OF BUTTER.

For the last seven or eight weeks I have been unable to eat any butter from the cream from one cow, all I have, which has been treated in every respect as she has usually been, when I have had no difficulty in the matter. The cow is the same, and appears in perfect health. Her food consists of mangolds and bran and chaff. Before churning, the churn is scalded out, and thus made warm, and the cream is warmed by being placed in hot water. When churned it thickens to a certain extent, and butter seems nearly formed; then of a sudden it seems to dilute, as it were, and no amount of churning can alter it again. What makes it more extraordinary is that twice since this has happened the butter came all right (and once in five minutes, the treatment being in every case the same, as was the food.—A. L.

[We publish the foregoing, because we have heard of similar instances, and we shall be obliged by any explicatory or remedial information. To obtain butter with the greatest certainty, and in perfection, the cream should be churned daily. This cannot be done where only one cow is kept. A temperature of 56° in the dairy causes all the cream in the milk to rise. There are times when a cow's milk differs very much from its ordinary state.]

OUR LETTER BOX.

VARIOUS (R. J. of E.).—The address of the Hon. Mrs. Arbuthnot is Inehmartine, Inchture, N. B. Mr. Pigeon, of Lynton, Devon, was very successful with La Fabe last year. Buy of some who advertise in our columns. There is a book called the "Standard of Excellence," published by the Poultry Club. We believe the price is 8s.

INDIAN CORN FOR FOWLS (Alpha).—We have nothing to add to or to alter in what we said on this subject. In our experience we find it too fattening for laying-hens.

MAIZE, OR INDIAN CORN (Gamma).—We are opposed to a maize diet, it is too fattening, and has not stay enough in it, nor are we friendly to glazed houses and such luxuries. They keep birds clean, but they neither produce eggs nor profit. If you will let your fowls live like fowls they will do well; but if you pet them they will be unprofitable, as pets mostly are. Let them out in all weathers, give them oat or barley meal mixed with water in the morning, a feed of maize at mid-day, meal again in the evening, and they will be less trouble and more profit.

ROOF (Subscriber).—With the advantages your chickens have they should have no sickness. We think that you allow the hen her liberty too soon; she will drag her chickens to death at this time of year. In the winter and early spring the hen should be under the rip (till the chickens are at least ten weeks old). Add chopped egg and bread and milk to your chickens' food, and give your Pantams bread and ale, and camphor in their water.

PULLET DYING SUDDENLY (A. Brown).—The death soon after laying, and the soft eggs you mention, the liberal feeding, and the confined space, lead to the conclusion that your poultry are too fat, and that the pullet died from a blood-vessel rupture on her brain. Give less food, and less nourishing food; omit the crushed barley and the dinner scraps. Have some linseed rubbish for the fowls to pick up.

SCALY LEGS OF COCHIN CHINAS (K. J. C.).—We are afraid your hens are no longer young. It is a proof of age, in almost every bird when the scales of the legs thicken and become hollow. It is cruel to pull them off, and the birds are by no means useless, because they are not young. Cochins are subject to this at an earlier age than any other breed.

BREEDING (L. A. D.).—In our opinion, no bird can be maintained without the judicious introduction of fresh blood. To breed in-and-in is to lose caste and quality. An inferior cross sometimes becomes necessary because the inferior bird possesses the quality its superior lacks. Those who are often at the head of the prize lists do themselves fortunate if they can be sure to reproduce that which has been already successful.

BLACK COCHINS (H. P.).—These birds were first bred in Cambridgeshire, and by a cross between White and Buff birds. They were shown at an exhibition at Chaceley Park. If properly judged by competent men, a Cochin cock with his sickles removed, would certainly be disqualified. Nothing tells with judges so strongly in favour of a bird as its being honestly shown.

SODDING EGGS (R. S.).—Two days, or even three days, before hatching, the eggs should be put in lukewarm water for ten minutes or more, and all that have live chickens in them are chattering and titing in all directions.

POWDER COCK (E. S. North).—I am afraid your Powder cock has a cancer in his crop, and the discharge from it is what you call "a milky kind of pap." If such is the case you had better kill him, unless you can feel from the outside that the cancer is detached. In that case you may open the crop, cut the cancer clean out, wash the crop clean, and sew it up. If, however, you think there is no cancer and it is only indigestion, try pills containing one grain of calomel on alternate days for a week, and feed on bread and milk soup; put, also, a little sulphate of iron or green coppers in his drink.—E. P. L.

INCUBATOR (Diplomat).—We have seen Prindley's Incubator, advertised in this Journal last week. It is very simple, easily managed, and so compact that it might stand by the fireside. The cover is of glass, so that the whole process of incubation may be witnessed.

CASARIES DYING (Canary Lover).—I have examined the seed sent. The hempseed contained a large proportion of light seeds; but the remainder, though small, were fresh and good. The Canary seed looked small and pale, and there were many whitish seeds amongst it. On tasting, the third seed had a hot unpleasant flavour, not unlike bad nuts, and a large proportion of the seed was so flavoured. There was a grain of rye among that sent, and that had a nasty taste. I am inclined to think that it was foreign seed; that it had been damaged and killed, and consequently that it was the cause of some birds dying. I am very sorry to hear of the death of so many nice birds, but it does occasionally happen to others besides. CASARIES LOVER, and we are all liable to lose our pets, and even to be poisoned and cured by other people's ignorance or carelessness. It is impossible for me to say with any certainty from such accidents can be insured against. I cannot recommend any dealer in particular, nor do I know anything about foreign birds.—E. P. L.

CANARY PECKING THE WIRE (G. G.).—The trick your bird Les of biting his wire cage, I think, is merely a habit and not a sign of illness; but if the wires are brass they may make him ill; therefore it would be advisable to put him in a cage with iron wires.—E. P. L.

REBBREASTS (John Dobson).—They are often kept in cages, and I do not think they are difficult to keep. London fanciers keep them in a Nottingham's cage; but I think such cages are scarcely large enough. I prefer a common breeding cage. Feed on chopped bread and cheese, a little cooked meat shred, fine stout pudding, boiled carrots, or hard-boiled eggs as a change, and with cleanliness and the use of the bath I have no doubt you will find them handy enough.—E. P. L.

TALKING AND TEACHING.—A PARROT (L. S. A.).—The bird should be kept in the room with you as much as possible, and frequently spoken to. Give it occasionally any little article you think that it may fancy, such as a piece of loaf sugar, apple, nuts, &c., but no meat, fat, or bones; every time you approach the cage speak kindly to the bird, and be careful not to allow any one to frighten, or even to feed it. It will be very sensitive to anything of the kind, and would not soon forget it. When giving it fresh food or cleaning it out continue to speak to it, and we have no doubt that the bird will shortly lose its wildness. Some are like children, more easily managed than others, and depending on the temper of both, but great kindness and affection will in time tame the most fractious. Any words you wish the bird to say repeat to it as often as possible, taking care always to repeat the same words.

TAYLOR'S AMATEUR'S BEEHIVE (B.).—It is highly priced. Write to Mr. W. J. Pettit, Hive Manufacturer, Dovers; or to his sister, Neighbour, Holborn, London.

TRANSFERRING BEES (C. A. M.).—Transferring bees from a common old-fashioned straw hive to a hive with supers, may be performed in April, and the middle of a fine day is the best time for doing so.

LIGURIAN BEES—WOOD-BY-HIVES (W. C.).—Mr. Woodbury, of Meant Radford, Exeter, will supply you with a stock of Ligurians, and will state their price upon application being made to him direct. The month of April is about the best time for obtaining them. Untraded eye straw is the best material for straw, and yellow pine for wooden hives. Full working instructions for making Woodbury's hives are given in the fifth edition of "Bee-keeping for the Many," published at this office, and sent free by post for five stamps.

COMMON AND LIGURIAN BEES IN ONE HIVE (A. R. Birmingham).—It is of no use to attempt isolating the Ligurians, unless you could keep them some miles distant from all other bees. The original Ligurian queen will breed pure Italians under any circumstances as long as she lives. The month of April is about the best time for transferring bees to frame-hives, and it will be well in so doing to remove surplus drone combs. You will find much valuable information bearing upon the subject of your letter in page 21 of our eighth Volume.

WEEKLY CALENDAR.

Day of Month	Day of Week	MARCH 20-26, 1866.	Average Temperature near London.			Rain in last 30 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 50.9; and its night temperature 33.15. The greatest heat was 69, on the 25th, 1833; and the lowest cold 14, on the 25th, 1850. The greatest fall of rain was 1.11 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse

STRAWBERRY CULTURE.

LUDGING from what I have seen and heard, many failed last season who had been successful in obtaining fair average crops of this fruit in previous years; the following may, therefore, interest some of your readers, especially as in my case the crop of 1865 was the finest I ever saw, particularly that of the British Queen. In 1864 I gathered in one day from six rows of Black Prince, twenty-four plants in a row, 96 lbs. of fruit for preserving. This crop was seen by many gardeners, who pronounced it to be the finest they had ever seen. My cultural operations do not differ much from Mr. Read's (see No. 256 of this Journal). In fact, while writing this I feel I am occupying space which might be better filled; but, as Mr. Read justly remarks, "a very important feature of THE JOURNAL OF HORTICULTURE is, that discussion and intercommunication are invited on all matters of interest to its readers," and I may add, that if such intercommunication, &c., is carried on in a friendly spirit it will do much to advance the cause of gardening and gardeners: therefore I offer this for insertion.

The sorts which I have found most satisfactory are the Black Prince for early, Keens' Seedling for second, and the British Queen for late production. On a north border the British Queen does well, and the fruit is about ten days later than when grown in the open bed. Several others of the older sorts have been tried, but are not so good as the above. The comparatively-new sorts I have not yet fairly tested, but the following I have now under trial:—Sir Charles Napier, Sir Harry, Frogmore Late Pine, Elton, Eleanor, Carolina Superba, Princess Alice Maude, and Oscar, of all which I will speak when they have fruited this season. I also intend trying all the new sorts as soon as I can obtain them, as good Strawberries are a great feature with my employers.

The varieties I first named supplied the table last year without intermission from the first week in April till the last week in July, a period of four months. I commenced picking forced Strawberries to-day (March 7th), and hope to continue somewhat later this season than last with some of the sorts above-named; therefore still further prolonging the season of this fruit.

I may mention that the soil here is a very heavy loam of one foot deep, resting on strong brick earth; this soil I believe to be more natural to the Strawberry than any other, for I have always found it do best in this description of soil. The following is the mode of culture which I have practised.

As early in the winter as possible I select a piece of ground well exposed to the sun, trench it to the depth of 2 feet, putting a good dressing of manure at the bottom, and laying the surface rough for the action of the frost. In spring a crop of Potatoes or any other vegetable of quick growth may be planted, but care should be taken to keep the soil quite free from weeds; for, from experience, I find that Strawberries dislike weeds as much as any plant I know.

Early in June I select from each well-established plant eight or ten of the best runners, and layer them in pots filled with rich soil (I prefer this method to pegging on the ground in heavy soil), keep them well watered till they have taken good root, which they will have done in about fifteen or twenty days if they have been properly layered, and the soil has not been allowed to become dry. They are then severed from the parent plants, and transferred to a place well exposed to become a little more hardened; meanwhile the crop is cleared from the ground, and a good dressing wheeled on, and dug in to the depth of 14 or 15 inches. The ground is then worked down nicely, and the plants carefully turned out of their pots, and planted in rows 2 feet 3 inches apart, and 2 feet asunder in the rows. Three rows are planted in a bed, leaving the space of 2 feet 9 inches between the third and fourth row; there is consequently room to pass between the rows to water, gather fruit, &c., without treading the bed all over alike or bruising the fruit at every step. The planting should be performed during the afternoon if possible, as water can be copiously given towards evening without much chance of damage; whilst if the plantation is watered in the forenoon, and the sun happen to shine brightly soon afterwards, more or less injury will be the result. The plants will now require plenty of water in dry weather. Liquid manure will greatly benefit them till September, by which time they will be well established, care being taken during the whole of their progress to keep the runners cut off and weeds pulled up as soon as seen; but I never allow a spade or fork to be used near the plants after they are planted.

As early in November as I can procure it I cover the ground with a lot of seaweed from the beach, and let it remain all the winter untouched: in spring the weeds will require attention again, but now and during the whole of the summer will be found the advantage of the mulching; it will prevent the weeds growing so fast as they otherwise would do, save watering to a great extent, and keep the fruit as clean as plates would, and as free from slugs, &c., as any precaution that could be adopted, whether tying or anything else. If seaweed fall short, I use short litter from the stable-yard, but, as Mr. Read remarks, ladies do not like the idea of eating Strawberries that have been laying on such material. Besides, the seaweed has another beneficial effect on the plants—the salt contained in the weed, when procured from the beach, is washed down to the roots, affording food to these, and keeping them nearer the surface. The directions for after-cropping &c., are the same as for the first year, only stronger liquid manure may be given as soon as the crop has been gathered. My experience on light soil has taught me that the ground

No. 260.—VOL. X., NEW SERIES.

should be made firm by treading, as soon as the plants are established and mulched as above; I have never found this to fail in producing a good crop of fruit.—JOHN MAY, *Westfield, Havant, Hants.*

STOCKS FOR GRAFTING ON, AND THE RESULTS.

HOWEVER artificial the process of grafting may appear to those who for the first time see it performed, it has its counterpart in nature: branches of trees overlying and pressing against each other eventually unite, and no doubt it was an example of this kind that first led some experimentalist to try to bring about the same result by tying two such branches together, or perhaps branches belonging to different trees. Success would induce further experiments, and eventually a scion taken from one plant and inserted in another was found to grow when the operation was performed at the proper season and in a suitable manner. The process most likely to lead to success was no doubt found out by degrees and after a due number of failures. How many centuries ago this portion of our craft was in course of perfecting itself, it is needless to inquire; but as there was no JOURNAL OF HORTICULTURE in those days, and the modes of disseminating information of every kind were slow and imperfect, we may readily infer that a new mode of effecting the desired object might not unlikely remain for a long time known only to the operator, especially if he assumed that mysterious secrecy in the matter which still lingered amongst some "knifemen" in large nurseries as lately as thirty or forty years ago, or perhaps still later than that. A stranger happening to stop and look at these mysterious workers was a signal that their knives wanted sharpening, that some scion had to be sought after, or that some work or other in the distance had to be done; thus the inquisitive looker-on never came at the right time to see the operation performed. Happily these times have passed away, and though dexterity in the manipulation enables one man to be more successful than another, there is no secret in the affair, and practice and experience, aided by other favourable circumstances, usually meet with success.

The out-door grafting of fruit trees is a very common affair in counties where orchards abound, and is often done very extensively by ordinary labourers. Certainly some little knowledge is necessary, but the time at which the work is done has more to do with the success than the mode of carrying it out. In Kent it is deferred till much later in the spring than is the custom in many places, and the result is usually satisfactory. I have seen several thousand scions put on in May, and nearly all grow. There is, however, a description of grafting much more difficult than that of ordinary fruit trees, the parts operated upon being so much smaller, and in some cases the affinity between stock and graft is not so great, leading to more uncertainty, and these cases seem multiplying every year. Thus any choice plant that it is necessary to propagate quickly, is at once "worked" in some way or other, and this "working," as it is called in nursery phrase, comprehends a considerable series of objects differing materially from each other, and, as stated above, their number is yearly extending; for not content with operating upon the class of plants having woody fibre, fleshy-rooted herbaceous plants now and then are grafted, and with success.

Of all the plants subjected to the operation of the knife, in the way of grafting, the Cactus is perhaps the most quickly and easily grafted, while some skill and dexterity is required to operate on a hundred Camellias and get ninety-nine of them to grow, and I believe there are many plants more difficult than this, and resinous plants are not always the most successfully managed. With many of the classes of variegated plants the chances of success are greater. Hollies are worked by the hundred, and the new deciduous plants with remarkable foliage, recently introduced from Japan, are no doubt thus propagated to the utmost extent that a skilful propagator can, and where stocks of a suitable kind are forthcoming, there seems to be no reason to doubt the after-success of the worked plants, whilst the peculiarities of each sort will in due time be presented by a greater number of individuals than there could have been had each plant been supported by its own roots only.

Grafting is also often performed by amateurs and experimentalists for purposes of curiosity only, and sometimes with rather singular results. I remember its being stated, about forty years ago, that when the purple *Cytisus* was budded or grafted on the *Labrum* (which it often was in those days), and did

not succeed, the contact of the bud or scion with the stock nevertheless exercised on the latter an effect that could be discerned in the bark, sap, or foliage. I believe the same to be the case with the Copper Beech, but of this I am not so certain. Grafting, however, is often practised on plants that may be termed only half-shrubby, or, in some cases, purely herbaceous. When double Dahlias first made their appearance, it was thought that the best way to increase them was by grafting the young shoots on the fleshy tubers of single varieties, which, like the single Camellia, were obtained in greater abundance. Geraniums have also often enough been grafted, but more for curiosity than with a view to multiplying the variety; and the same may be said of the *Fuchsia*. Azaleas, however, are now almost all subjected to the "working" system, and with good results; and Rhododendrons of the best varieties could never have been increased so rapidly had recourse not been had to the assistance of other less-favoured members of the family to act as stocks. Many other plants are in a like manner increased to a wonderful extent by grafting and budding, and more are daily being subjected to these modes of propagation.

It need not be wondered at that a proceeding so fraught with advantages should also have its drawbacks, that now and then differences of opinion should exist as to some of its details, that there should be differences of opinion on the merits of the stocks used. I believe Mr. Barnes, of the Camberwell Nursery, was the first to point out the best stock on which to work the Indian Azalea, and a few years ago there was some contention amongst Rose-growers, as to whom was due the merit of first trying the Manetti stock for the Rose; latterly, however, there has been some difference of opinion about this stock, and the Briar has been again put forward. Of the respective merits of these stocks it is not my intention to offer an opinion; but I would like to see both dispensed with if Roses could be coaxed to grow on their own roots. This subject, however, has been already discussed by several writers in the JOURNAL OF HORTICULTURE, and, in connection with it, I will only allude to a plan that has been of late adverted to by several—that of planting Roses worked on the Manetti so deeply as to bury part of the plant as well as the stock, a proceeding which is said to facilitate the production of roots above the graft, and some writers have advised the stock and lower roots to be cut away when the upper tier are formed. If the Manetti is of no further use than this plan would imply the sooner it is done away with the better, and the plant started on its own roots, instead of having to suffer the inconvenience of its foundation being cut away. Besides, unless the plants are worked very low indeed, planting them in their final quarters so much deeper in the ground than they were before, must be hurtful in other ways, as there are comparatively few plants that like to be planted so deeply, however prone they may be to send their roots downwards. We ought as far as possible to imitate Nature in all her works, but we see no instance in which she buries the collar below the surface, why, therefore, should we do so? Assuredly the result is no better. It may, however, be said, that transplanting is an artificial proceeding altogether, and so it is, for with the exception of trees or plants being torn up and washed away by floods in rivers, or such tornados as we hear of in tropical countries, and deposited somewhere by accident where they can grow, the transplanting of trees by natural means is less common than grafting, so that there is no analogy between the two; but layering is a purely natural mode of multiplying plants, and seed still more so, and rooting in both these cases is from the surface. All this has been repeatedly urged by the advocates for shallow planting.

Instead of pursuing the subject of Rose stocks further, I will now enter on that of stocks as adapted for fruit trees, which has again, for at least the twentieth time, occasioned discussion in the pages of gardening periodicals, and latterly I was sorry to see that a bitterness of spirit was imported into the matter which ought not to have been, especially as the difference of opinion seems to be one likely to affect all kinds of grafted or worked plants, and I may add many that are not worked. In other words, it may be taken for granted that every tree planted deeper than is good for it, endeavours to correct the error that it made, by directing its roots to the surface, or if it is incapable of so doing, it will in many cases emit roots from that part of its stem which is just sufficiently below the surface to protect the roots when young from the effects of dry weather; or, where sufficient moisture can be obtained, the roots are formed on the very surface, as sometimes is the case with Willows in swampy ground; or a still more notable example is

that of the Grape Vine, which under favourable circumstances sends out roots innumerable into the tempting humid atmosphere. But more on this head when the subject of stocks has been adverted to.

It would be difficult to trace back the history of the stocks that have been at times recommended for our ordinary fruits. The Peach and Almond for the Peach, Quince and White Thorn for the Pear, and the Paradise Apple for the Apple, must assuredly have been tried long ago, and by successive writers and practitioners recommended at various times in preference to the stocks most generally in use. Now, though foreigners, especially Americans, say we are slow at availing ourselves of advantages within our reach, assuredly if the stocks above named had possessed superior merit to those they were tried against, there is, and has been, sufficient discernment in the cultivators of these fruits to perceive it, and these stocks would have made their way into general use long ago. However, these stocks are not the most generally used at the present day, and it behoves us to find some solution as to, in schoolboy phrase, "the reason why."

Commencing with the Peach—I well remember the time when the Peach stock was hailed as a step in the right direction, and was expected to do wonders, the knotty protuberance so manifest in most Peach trees worked on the Plum stock, was an eyesore said to give way when a Peach stock was substituted, and I have certainly seen some fine trees so grown, but by-and-by it was whispered about that now and then such a tree would fall into ill-health, and in spite of its being supported by one of its own kin, death would overtake it at an early age. The Almond, I believe, was still more liable to this misfortune, and though trees on both stocks may occasionally be met with, they are not in sufficient number, nor in such a healthy and vigorous state as to warrant the general adoption of these stocks. The reason of the Peach stock not answering would seem to be its inability to perfect itself and the variety worked on it in our cold soils, and in the dull summers of this country as compared with those of its native land, while the Plum, being probably indigenous, performs the task better. Local circumstances, doubtless, modify these results, and some places favour the growth of the Peach stock; but as a rule these places are few, and there are, perhaps, fewer trees worked in this way now than twenty years ago.

Taking the Pear next, the comparative merits of the Pear and Quince stocks ought not to be judged by the same standard as that which guided the decision in the case of the Peach, for both are hardy. I will say nothing of the Pear on the White Thorn, Mountain Ash, and other stocks on which it is said to be grown, but most generally as an object of curiosity, but will proceed to the merits of the two stocks on which the tree is most commonly worked, and on which the controversy has lately turned, and endeavour to offer some solution of this knotty question. In the first place, let us examine the two plants as they generally present themselves, and, reasoning from that, the truth may, perhaps, be arrived at. On examining the two what a difference will be perceived in their growth, that was not before thought of. In this county both fruits, especially the Pear, are grown somewhat extensively. The Quince is certainly not so much grown in this neighbourhood, and only now and then a tree is met with until we travel a few miles farther, and then this fruit is seen in all its glory. Now, it is not my intention by any means to condemn the Quince as a stock for the Pear, on the contrary, there are some cases in which most likely it may be used with advantage. I am, nevertheless, of opinion that there is no instance in which a Pear so worked has produced anything like the quantity of fruit it has done when grown on a stock of its own kind. The Quince seems altogether of more limited growth, and in no case when I have seen it has it approached the majestic growth of the Pear tree, when on a stock better suited to its requirements. Taking the quantity of fruit that full-sized trees of each kind may be said to produce, I have in no instance seen a Quince tree yield more than one-fourth of what the Pear will do, and this is a wide difference. Certainly this immediate district favours the Pear tree more than the Quince, but I have not heard of the latter assuming anything like the proportions of the former in any place where it is grown.

It is just, therefore, to assume that the Quince is of humbler growth, and, consequently, more likely to check the growth of what it has to support than to augment it, and as such may be more useful when trees are grown in a dwarfed or stunted condition, as small pyramids, or against low trellises, walls, or the like, instead of assuming the lofty proportions and vigor-

ous condition that would result from the tree being worked on a stock of its own kind; but this condition of things is also modified in other places, where it is possible that the Quince may be of service; for the Pear and Quince do not by any means both like the same soil, and here is the secret of much of that difference of results which is sometimes attributed to mere opinion. The Quince grown as an independent fruit tree thrives best in a damp place, say by the side of a ditch, or in a similar position not too dry nor light. The Pear, on the contrary, seems to thrive best on a dry stony soil that will allow its roots to descend to a good depth, and still to find nourishment in the open stratum through which they pass, the whole being free from all stagnant water, and ready to receive any amount of rainfall without showing much difference at top. Such a soil is the one in the immediate neighbourhood of this place, where the Pear is to some extent cultivated, though not to the same degree as the Plum, Apple, and Filbert. Still there are many thousands of bushels grown in favourable years at no great distance from us, and these are mostly produced on large standard trees on stocks of their own kind, with trunks a foot or more in diameter, and scarcely showing any signs of ever having been worked, the stock and scion keeping pace with each other. I will not say how many sieves report has given credit for one of these large trees yielding in a favourable season, but the produce is said to exceed that of any Apple tree. The fruit of the Quince may very often be all gathered without the use of a ladder, the trees being so low; but then I am not certain the Pear tree would not be small in such a place also; therefore, we must not confuse the relative position of the trees, but, taking the matter in its broadest sense of competitive merit, ask whether the Pear grown on the Quince stock in the most favourable situation for that stock, or the Pear grown on its own stock in its most suitable position, produces the more fruit of good quality. I, for one, have no hesitation in giving the palm of merit to the latter; other growers may, perhaps, think differently. What is here stated may, perhaps, provoke discussion; if so, let it be of that courteous kind which becomes the calling in which we are all engaged.

My remarks on the Pear having been extended further than I purposed, but little will be said on the Paradise stock for the Apple. Its only merit, so far as I could ever learn, is, that it tends to dwarf the growth of the variety grafted upon it. Some of its admirers assume that trees on the Paradise begin to bear sooner, but that is questionable, and most certainly a smaller quantity of fruit is produced on a given number of trees of, say, ten years old, of this kind than by those on other stocks, when the advantages are alike; and possibly in cases in which the trees supported on the Paradise stock do so well, this result is due to the soil and situation favouring that variety. I imagine, however, that it is not the same sort of soil as that mentioned as being the best for the Quince, but, on the contrary, a dry soil; yet on this point I am by no means certain, for I have had little experience with the Paradise stock, and have yet to learn any advantages it possesses over the more common Crab. The desire for novelty and a wish to have something different from their neighbours are inherent in many persons, and these feelings are laudable too in their way; they have at various times during the last fifty years called the Paradise stock into notice, but it has never to my knowledge made that figure in the world that its antagonist has done, and for every basketful so produced, some waggon-loads may be set down on the other side; therefore, unless as above stated for some special purpose, the use of the Paradise stock is not advisable. It may, nevertheless, be worthy of notice from those who prefer a single fruit to a bushel of the same obtained in the common way, and such persons are justified in riding their hobbies as hard as they like, but the market basket would be long in being filled by this plan, and that after all is, perhaps, the true way of looking at the matter.

With regard to planting fruit trees so deeply in the ground as to bury the part worked 4 or 5 inches under the surface, and induce the upper portion to emit roots, no better argument could be used against working at all; but, independently of that, is not planting so deeply bad practice? In general shallow planting is recommended, everywhere I might almost say, and to reverse this merely to induce the formation of roots where none existed before will no doubt effect that object, but that does not by any means justify the means adopted. Within a mile of where I now write, there are hundreds of Apple and Cherry trees that have been planted on the surface and the soil heaped on the roots, making a mound of about half a cart-

load or so around the collar of each tree, and the result is favourable. Gooseberries and Currants have sometimes been treated in the same way, but the plan is all but abandoned, and in the case of Apples only a few practise it. Cherries, however, on stiff ground seem to be benefited by the practice, but on dry stony soils of upland districts the benefit is less apparent, and the plan has been abandoned by many growers; nevertheless, some old hands still adhere to it. There is an inconvenience attending it where the ground is in tillage, but when in grass this is not the case.

I cannot conclude this article without thanking Mr. Pearson for his excellent article on the Camellia, a plant which is managed the reverse of well in many places, and though I hardly agree with him altogether as to the soil he recommends, I am far from being certain that he is wrong. Most excellent Camellias are grown in different parts of Yorkshire, and, no doubt, in the adjoining counties also, and advice from growers there is valuable; but somehow I have always been of opinion that the water a plant is fed with exercises as much influence on its well-doing as the soil it is grown in. For instance, water from a chalk well, continuously supplied to Heaths planted in peat, in time is fatal to the plants. Rain water we are perfectly assured is in all cases grateful, and for tender plants ought always to be used.—J. ROBINSON.

PEAR SCIONS ROOTING.

I HAVE read with lively interest the discussion on Pear scions emitting roots above the stock. The affirmative I can fully endorse by practical proof. I have very recently been transplanting a number of Pear trees, and one of them is ready for Mr. Scott with a beautiful bunch of roots "from above the junction of the scion and stock." The spongelets are very fat and active, while those of the stock are dormant. The tree is a standard, about 5 feet high, stem 2 inches in diameter. If Mr. Scott will send me a dozen Mrs. Pollock Geraniums I will send him the tree for ocular demonstration. Of course he will pay the £1 to the Institution.—T. MIDDLETON, *Gardener to Sir W. B. Wynne.*

WINTERING VERBENAS UNDER BELL GLASSES.

HAVING for the last four years adopted a particular method of wintering Verbenas, Calceolarias, Lobelias, Ageratum, and even Pelargoniums, which I have never seen described, I venture to give my experience and mode of proceeding, not for the purpose of instructing professed gardeners, but in order to bring this class of plants more within the reach of such amateurs and cottagers as cannot or will not afford themselves the luxury of a greenhouse or frame. Even by those who possess these useful adjuncts to a garden, this mode of keeping them through either a wet or frosty winter will be found easier and more certain than the old systems. That it may not prove a success with all on the first trial is probable, but it should not, therefore, be hastily condemned, for many will set about it the wrong way, or omit doing something essential to success.

The advantages of the method are, that the first outlay is small, that the skill required to succeed is only such as is possessed by every one who cultivates plants as a pastime, and that very little labour is required. That I was not so successful the first season as I now am is true; but since I adopted this method I have never been without a sufficient supply of these usually fastidious pets, and most seasons I have plenty to spare for my more unfortunate neighbours.

The time for commencing operations is not the same for all the above-mentioned plants. Verbenas should be put in from the beginning to the end of October; though I have done so and succeeded as late as the 25th of November, I do not advise waiting so late. For Ageratum and Calceolarias my advice is, wait as late as you possibly can, but insert the cuttings before the plants are affected by frost.

This is my mode of proceeding:—A fortnight before propagating I dig a border 2 feet wide and long in proportion to the number of bell-glasses required. It should be immediately under a south wall, and slope from the wall so that the water may be thrown off. Over this border spread sand an inch thick, and fork it well in, so as to make a sandy open soil in which to plant the cuttings. On this I place the bell-glasses

for a few days before planting, that the soil may become heated. I make my cuttings in the usual way, and dibble them in as thickly as possible—say about half an inch apart. I have now of Purple King Verbena a bell-glass 16 inches in diameter, in which were put a hundred cuttings; eighty-eight are looking well, and have already furnished one set of cuttings, the others were devoured by a slug which found its way in, and grew fat on Verbenas for a few days, but *requiescat in pace*. I then give a good drenching with water at 90°, put on the bell-glass whilst the soil is still muddy, press the glass down firmly, shade from strong sun, and water over and around the bell-glass every third morning until the cuttings begin to shoot. As soon as they start I give air by removing the glass on every fine day, and occasionally wipe the inside, and I fork the soil among the plants. If kept well aired and tolerably dry a little frost will not hurt the cuttings, though if the frost become severe protection must be given by means of a sheaf of straw, tied together at one end, and of a convenient length, so that when pushed over the top of the bell-glass it may cover it all round. Treat the Ageratum, Lobelias, and Calceolarias in the same way, and in March each Verbena will furnish two cuttings, which may be struck as before, and each Ageratum and Calceolaria will afford one cutting. I have wintered Pelargoniums and Fuchsias in precisely the same manner. Though I do not recommend this method for them, it is better than fagotting them in a cellar.

The objections which may be raised against this system are:—Firstly, That the roots are necessarily more or less injured at bedding-out time. Secondly, That the plan may do for a mild climate, but will not answer in a cold one. Thirdly, That if the climate is very wet, damp will be the destroying agent.

To the first objection I will answer, that though the roots may be a little broken, and the plants require water and a little attention for a few days after planting out, they do not sustain material injury, and will prove hardier and less liable to mildew than if they were pot-bound, or allowed to become too dry in winter.

To the second objection my answer is, that where my bell-glasses stood last winter the thermometer registered 25° for three consecutive nights, yet not a plant suffered.

With regard to the third objection, I may remark that this winter has been a severe test, for we have scarcely been two days without rain, yet not a single plant has damped off, or shown an inclination to do so. The Lobelias and Calceolarias are, perhaps, a trifle too tender, but exposure to March winds will put that all right.—PURPLE KING.

[We know that most of what "PURPLE KING" relates can be done, but only by care and watchfulness. In such positions hand-lights have been used pretty successfully. In fine weather they are better, in bad weather they are not so good as large bell-glasses. As our correspondent speaks of the little expense, we presume he uses those of coarse coloured glass. Good bell-glasses of clear glass, 16 inches in diameter, cost about 3s. 6d., and they are expensive and liable to break in carriage. We once had a narrow pit close to a wall under our care, and there Neapolitan Violets and bedding stuff flourished amazingly, the glass being protected by straw covers and straw mats, and the ground in front rough-asphalted with tar and gravel to throw off the damp and wet. With rough glass in large squares at 1½d. per foot much may thus be done with narrow pits—say 2 or 3 feet wide, in front of a thick wall. The bell-glass system might suit some people much better, as they are made all ready for use, and our correspondent would confer a further favour by telling us the size and price of his glasses, and the quality and colour of the glass. We duly appreciate the skill and the unwearied watchfulness he has exercised over his pets.]

CULTURE OF VERBENAS FOR BEDDING-OUT.

SOME of your readers seem to find a difficulty in the cultivation of Verbenas; my mode of growing them always successfully is as follows.

In the latter part of July I take cuttings, and insert them in a mixture of light loam and leaf mould, with a sprinkling of silver sand, in 48-sized pots well drained, and plunge these up to their rims in some old tan in a two-light frame on a gentle hotbed. When the cuttings are rooted I pot them off into 60-pots, and place them in their previous quarters till they have roothold. They are then placed on a shelf in a cool vinery, and remain there till spring, to be then removed to a cold frame to await their being transplanted into the flower

garden. Should any of your readers try the above plan, I feel sure they will not fail in successfully cultivating the Verbena.—H. C. O.

HEATING BY A FLUE. AND CHIMNEY DISTANT.

I HAVE a small span-roof greenhouse, 16 feet by 9 feet, and 10 feet high, which I intend heating with a flue. Opposite and parallel to the greenhouse, and distant from it about 9 yards, stands a brick summer-house. It stands about 2 feet higher than the greenhouse. I intend pulling it down, and putting two frames in its place. As I do not wish to be at the trouble of building a chimney to the greenhouse, I have been thinking it might be possible to use the summer-house chimney for carrying away smoke from the greenhouse flue, and wish your advice about the following.

I intend building the fireplace outside the greenhouse at the door end, and at the back of the door close to the greenhouse; the flue to enter the greenhouse and run along the back, then along the end, and back along the front to within a foot of the doorway, and leave the house there. On leaving the house I intend it to dip down about 18 inches, and pass along underground in an uphill direction about 9 yards. At the end of the underground part I intend it to rise into an aboveground flue, which will be about 14 feet long, under the two frames, they being placed on the present site of the summer-house. After the flue passes through the frames it will end in the present summer-house chimney. My reason for having the underground part is, the flue would require to cross the principal walk of my ground.

Query 1st, Would it be better to build the fire altogether outside, or inside with the door to the outside of the house?

2nd, By the above plan do you think there would be a sufficient draught of air to keep the fire going and heat the greenhouse flue?

3rd, Would there be any heat after passing through the ground, to be of use in a frame for raising plants from seeds and cuttings?—W. B. M. L.

[There are two things against your proposed plan answering well. First, the proposed dip of your flue, 18 inches, after going round your house, and then passing in a lower level, though rising for 27 feet, until it gets above the ground again for 14 feet, and then passes into the garden arbour-house chimney. The dipping would be of less consequence if at once you rose from the dip to the original or a higher level. It would require a high chimney to secure a draught with such a dip and the low level afterwards, as heated air, like heated water, has a disinclination to descend. Then, again, your 27 feet of flue sunk beneath the ground will be apt to get damp, as we see nothing of the flue being protected, and that will impair the draught. Then, again, you will waste more fuel than is necessary if, after making a flue some 40 feet long for your house, you continue that flue some 27 feet out of doors, and then 14 feet to heat two frames in the position of the summer-house, and chiefly for the sake of the summer-house chimney. Now, first, as a question of economies, we would be content to heat the greenhouse as you propose with the flue, and have a small chimney at the end to which the flue returns; and that need not frighten you, as an iron pipe 7 inches wide and 7 feet long would do, or three or four hard-burned earthenware pipes, some 6 to 7 inches in diameter and from 2 to 2½ feet long, as used for drainage purposes, would make a chimney at once. After the flue had run more than 40 feet there would be no danger of cracking. We think this would be a much easier thing than building 27 feet of a flue underground, in order that it might give out a little heat to 14 feet further on, so as to get to a chimney. But

2ndly, It is natural that we should like our own ideas best if they can be at all carried out; and we think you may do all and more than you propose if the ground will permit of your sinking your furnace deep enough, so as to have the flues in the house lower than the level of the path outside which you must cross. We do not know the arrangement of your span-roofed house 9 feet wide inside, but we think the best would be to have the pathway down the centre; and if you put your flue or flues beneath the pathway, the top of the flue forming the pathway in fact, then you might pass your outside walk without dipping, and continue in the same or a rising level all the way to the summer-house chimney; and if you liked you might cover the flue all the way from the outside pathway with

frames or pits, the greatest heat being found nearest to the greenhouse. This would be a capital plan for keeping lots of plants, and securing early vegetables, &c., and the flue would act better than when exposed to all weathers for 27 feet. We should like to know how you decide. We have said flue or flues beneath the centre pathway of the greenhouse. If single, it would require to be 14 or 15 inches wide, outside measure. If double, each 9 inches wide at least, outside measure. Now to the questions.

1, Have the fireplace outside the house by all means, the outside flush with the end wall of the house. The furnace-bars may therefore be inside the house, and should be 18 inches at least beneath the bottom of the flue.

2, We think the unprotected (except by earth) covering of the flue out of doors, would promote dampness and arrest draught.

3, The heat outside the house for raising cuttings, seedlings, would be most effectual in frames placed as near to the greenhouse as possible. Would it not be possible to have a small pit outside your greenhouse, the side wall of your greenhouse forming the back of the pit, and turn your flue into that?]

FUMIGATING — SYRINGING WITH HOT SEWAGE—LAPSTONE KIDNEY POTATO.

I WILL answer "A BEGINNER" by stating that I never syringe my orchard-house trees from the time the blossoms first peep from the buds till the fruit is set, a dry airy atmosphere being necessary for the dispersion of the pollen.

My orchard-house adjoins another house filled with a miscellaneous collection of plants, and the latter I watch narrowly at this time of year in order to detect the first sign of green fly. About a fortnight ago I observed this insect on some Calceolarias, and, to take measures against it, I merely waited for the glass to become coated with snow, according to Mr. Fish's excellent hint, for I knew by the appearance of the sky that I should not have to wait very long. In the eighth volume of the Old Series of this Journal I gave the accompanying illustration of the contrivance which I use in fumigating a single plant in a large pot, and I have the original by me now. It is made of hoops joined to uprights, and is covered with some old moreen curtains so as to confine the smoke. I have always found it excellent for the purpose of fumigating a single bush tree, or a limited number of small plants.

The mode of operating is very simple and very effectual. When we receive a loaf of sugar from the grocer, with a wrapper of blue paper coarser than common, I seize it, and cut it into strips about 10 inches broad. I then place on the fire the liquid-mature saucepan containing about two quarts of water, a quarter of a pound of coarse shag tobacco, and one ounce of saltpetre, and boil the ingredients for half an hour. I next strain the liquid from the tobacco, return the former into the saucepan along with the strips of paper, which are loosely rolled up, and allow the liquid to become again heated and to thoroughly saturate the paper. I then place the pot on one side till its contents become cold, unroll and thoroughly dry the paper, and what liquid remains in the pot unabsorbed by the paper may be added to six times its bulk of water, and be employed for syringing.

The paper thus treated becomes like touch-paper, and is used to form self-acting cigars for fumigating. To fumigate a house say 20 feet long by 14 feet wide, six cigars would be required. I form them thus: I divide three ounces of tobacco into half ounces, cut six pieces of the prepared paper, each about 8 inches long, spread the tobacco equally over their surfaces, roll up loosely, and merely fasten the end of the paper at the bottom with a pin to prevent its uncoiling. Now if the roof of the house to be fumigated is covered with snow, or if not, at evening or on a dull day, place six small empty flower-pots equidistant on the floor of the house, and let each of them be furnished with a cigar; then apply a lighted match to the latter, and the tobacco will be gradually consumed through the smouldering of the touch-paper. The operator who dislikes the fumes may immediately make his or her exit, and return next morning to find the insects all dead, which is exactly what I did.

I fumigated the orchard-house at the same time as the plant-house, to prevent the insects finding their way from the

one to the other; but always, excepting from the bursting of the buds up to the time of the fruit setting, and from the beginning of the softening to the ripening of the fruit, commend me to the hot ammoniacal fumes of house sewage. One cigar would be sufficient to fumigate the crinoline contrivance, or a two-light Cucumber-frame.

Now with regard to the inquiries of "A BEGINNER." "First, how often the syringing is recommended to be used to trees in an orchard-house when free from insects?" I answer, That depends entirely upon "A BEGINNER's" inclination and time. From the setting of the fruit up to its last swelling for ripening an application every evening, if bright fine weather prevails, would benefit the foliage; and the same may be said from the gathering of the fruit to the maturation and fall of the leaf. When, however, the wind is in the east, and dark murky clouds move sluggishly over the firmament, if fruit and a healthy foliage are the objects in view, the trees must be indefatigably syringed with the sewage morning and evening.

"Second, how often is it recommended for borders in an orchard-house, to be syringed for the purpose of filling the house with steam?" I answer, As a matter of course the borders must necessarily become moistened every time the trees are syringed; but if roots are there, give the border a thorough deluging with sewage once a-week whilst the fruit is arriving at maturity, and the same may be done to the soil in pots, and in fine hot weather the latter must be watered with pure water every day on which the sewage is not applied. For a vinery, by syringing the hot sewage from pail to pail, the house soon becomes filled with steam. Soak the borders both inside and out once a-week, only desisting as soon as the Grapes begin to colour. In 1864 I continued syringing overhead my Vines in the house till the Grapes became ripe. The bloom stood it better than I could have thought possible. Last year I never syringed after the Grapes were set, but continued the sewage-steaming and saturated the borders once a-week. I shall continue the latter plan for Vines under glass, as being what I consider much the best. The heated ammoniacal gases prove sufficiently pungent to maintain the Grape foliage in health, and to prevent red spider; but Peaches, Nectarines, and Plums in an orchard-house require the direct application to their foliage.

I advise a "A BEGINNER" to adopt the mixture of horse-droppings and malt-dust which Mr. Rivers recommends in his work, the "Orchard House." I have used it two years as a top-dressing for my pots, and not only for fruit, but for Myrtles, Heliotropes, Geraniums, &c. I find it most excellent for the purpose, and it always remains porous so as to allow of water passing down, and, as a matter of course, air as well. I am of opinion that whole borders, wherever they may be, would be vastly benefited during the heat of summer by a surfacing of this mixture.

I beg to inform "D. Deal," that the raiser of the Lapstone Kidney was Major Haigh, a shoemaker, who formerly lived at Bartsay, near Leeds. Haigh first raised the Kidney bearing his name. It is a fine stained purple sort, throwing very meagre brittle haulm, a spare cropper, one of the firmly-mealy class, and richest of the esculents. Afterwards Haigh raised the "Cobbler's Lapstone," which he dubbed so because many of the finest tubers bore a resemblance to his lapstone. Haigh died in 1856. Honour to the "benefactor of his country" who raised two excellent sorts of Potatoes—honour even in a greater ratio than that commonly accorded to the "two-blades-of-grass" men.—UPWARDS AND ONWARDS.

PREVENTING FICUS ELASTICA BLEEDING.

HAVING noticed in the Journal, a short time since, an application for a remedy to prevent *Ficus elastica* bleeding when headed back, I send you a simple but effectual remedy if you think it worth publishing. It merely consists in heating some silver sand to about 130°, and applying it to the wound the moment the cutting is taken off. One application I generally find sufficient; but should the sap be very lively it is easy to repeat the dose. This may be a very old remedy, but I have not yet seen it in print, and having tried it successfully on several species of *Ficus*, I thought probably it might prove of use to some of your subscribers.—R. H. LEE, Propagator, *Battersa Park*.

MR. J. GOULD VEITCH.—We have the pleasure to announce the safe return of Mr. J. Gould Veitch from his botanical ex-

plorations in the South Seas and Australia; and to observe that he and his brother, Mr. Harry J. Veitch, have been received as partners into the extensive nursery and seed establishments at Chelsea and Coombe Wood, which will in future be conducted under the designation of James Veitch & Sons. *Flercant!*

ROYAL HORTICULTURAL SOCIETY.

FIRST SPRING SHOW.—The first of the special shows for the season was held on Thursday last, the 15th inst., in the eastern conservatory arcade, and notwithstanding the keen wind and ungenial temperature, which no doubt had the effect of deterring many exhibitors from coming forward, and of keeping away a large number of visitors, there was an excellent attendance of both. The display altogether was one of the best that have been seen of late years so early in the season; not only did the Hyacinths present an imposing array most brilliant and varied in colour, but there were gay Tulips in abundance, long lines of Crocuses, beautiful Roses, and a good number of stove and greenhouse plants, forced shrubs, &c.

Hyacinths have certainly never been seen in greater perfection, if, indeed, they have been equalled at any previous show; and though Mr. William Paul and Messrs. Cutbush were, as usual, pre-eminent, other exhibitors came forward; and that which is not so usual, their productions, though falling short of those from the above veteran growers, were of considerable merit.

In Class 1, for eighteen distinct varieties from nurserymen, two splendid collections were shown. That from Mr. William Paul, to which was awarded the first prize, contained spikes which for size, and for freshness and brightness of colour, even surpassed his previous efforts. There was an air of nobility about the spikes that it is difficult to describe, but which was most striking. Fore-most among the single blue class in this collection was King of the Blues, and a magnificent spike it was; the others were Grand Lilas, Charles Dickens, and Marie. Double varieties of the same colour consisted of Van Speyk, Garrick, and Laurens Koster; and the very dark shades approaching to black, were represented by Fernck Khan and General Havelock. Of reds—Gariibaldi, Von Schiller, Solfaterre, Koh-i-Noor, and Macaulay, were most brilliant, and the spikes very fine; and so, too, was that of Lord Wellington, double pale bluish, serving as a connecting link with the white class, of which there were Mont Blanc and Alba maxima, the latter remarkably fine. Ida, the best of the yellows, completes the list.

Messrs. Cutbush, as already remarked, had also a splendid set of eighteen, but some of the flowers had not reached that perfection which they would evidently have attained a week later. This collection received the second prize. It consisted of blues—Charles Dickens, Bleu Aimable, Marie, Grand Lilas, Baron Von Tuyl, and Laurens Koster; reds—Von Schiller, Solfaterre, and Macaulay, very brilliant; Howard, Florence Nightingale, Princess Clothilde, and Cavaignac; Robert Fortune, mauve; Grandeur a Merveille, pale bluish, a splendid spike; La Vestale and Mont Blanc, white; and an excellent spike of Ida, yellow.

Mr. Kirtland, Allion Nursery, Stoke Newington, came third with a very good collection, in which the most noticeable were Orondates, Von Schiller, Sultan's Favourite, Charles Dickens, Van Speyk, Mont Blanc, Gigantea, and Mimosa.

The next class was for twelve Hyacinths, of six kinds, amateurs only. The competitors were Mr. Young, gardener to R. Barclay, Esq., Highgate, and Mr. Bartlett, Shaftesbury Road, Hammer-smith, who were awarded the first and second prizes respectively; and it is worthy of remark that their collections, both in this and other classes, were much superior to those generally shown in previous years by amateurs. Among the kinds shown were—Queen of the Netherlands, Sultan's Favourite, Von Schiller, Mont Blanc, Nimrod, Mimosa, Charles Dickens, &c.

Class 5 was for six Hyacinths, and open to nurserymen and amateurs. Here, again, Mr. W. Paul was first, with splendid spikes of King of the Blues, Van Speyk, Macaulay, Koh-i-Noor, Alba maxima, and Ida. Messrs. Cutbush and Mr. Kirtland were equal second, and Mr. Young third.

Of Hyacinths grown in pots and glasses in windows, the best came from Mr. Bartlett, and were in pots. Mrs. L. Young, Kentish Town, and Mr. Beach, gardener to W. Rogers, Esq., Redhill, were respectively second and third.

New Hyacinths were shown by Mr. W. Paul, Messrs. Cutbush, and Mr. Young. Those from Mr. Paul, who took the first prize, were Vauxbank, a brilliant scarlet crimson, which, as well as Princess Mary of Cambridge, lilac, appeared to be decided acquisitions; Sir Henry Havelock, purplish plum; Adelina Patti, like Robert Fortune in colour; Bird of Paradise, resembling Ida in colour; and Sir E. Landseer, a showy rosy crimson. Messrs. Cutbush, who were second, had Arnold's Prince, purplish plum, a desirable colour; Grand Vainqueur, pale rose striped with pink; Orion, violet, with good-sized bells; Anrioulos Oog, purplish violet with a white eye; Hogarth, a pleasing rose pink; and Mrs. James Cutbush, white, in the way of Snowball, but with a larger truss. From Mr. Young came Sir E. Landseer, deep mauve, good spike; General Pelissier, porcelain blue; Mary, a promising white; Annie Lisle, rosy red; and Omphale, bluish. A third prize was awarded for these.

It now only remains to notice a collection of 120 pots, furnished by Mr. W. Paul, and comprising magnificent examples of most of the best known varieties. Among blues, here, as elsewhere, King of the Blues was the finest of the dark shades of that colour, and of the lighter varieties Charles Dickens, Grand Lilas, Couronne de Celle, Lord Cowley, Bloksberg, and Van Speyk, were conspicuous. The very dark, almost black shades, were represented by General Havelock, Prince Albert, Feruch Khan, and Von Humboldt. Reds were numerous, and besides these already enumerated, consisted of Reine des Jacinthes, Ornement de la Nature, Cavaignac, and Beauty of Waltham; whilst of the bluish varieties, Lord Wellington and Grandeur à Merveille were particularly fine. Haydn and Adelina Patti were conspicuous on account of their mauve tinge, and Ida was apparently the best yellow. Of the white class there were besides Queen of Netherlands, Alba maxima, and Mont Blanc, very good examples of Orondates, Mirandoline, Snowball, and Madame de Staël.

Tulips were shown in twelves in two classes by nurserymen and amateurs respectively. Of the former Mr. W. Paul was first with Keizerskroon, very showy, Proserpine, a very fine purplish rose, the well-known Yellow and White Pottelbakker, Globe de Rigant, purplish streaked with white, and Couleur Cardinal, a showy red. Messrs. Cutbush, who were second, had Keizerskroon, Cramoie Royale, Cramoie Superbe, Duc d'Artemberg, and Duchesse de Parme, red and yellow, the latter very showy. In the Amateurs' classes Mr. Young was first, Mr. Bartlett second, the kinds being Tourmesol, Vermillion Brilliant, and others already named; and in addition an extensive and fine collection was exhibited by Mr. W. Paul, and one came from Mr. Bartlett, which was also very good, though not so numerous.

Narcissi were not numerous. Those from Mr. W. Paul were first, and consisted of Bazelman Major; Newton, yellow; Grand Primo Citronier, white and yellow; Queen of Yellows; Gloriosa, a fine white with a yellow cup. From Mr. Macintosh, Hummersmith, who was second, came Paper White, a pretty pure white, Grand Soleil d'Or, Grand Primo, and others; and collections were also furnished by Messrs. Cutbush and Mr. Young, to whom equal third prizes were given.

Crocuses made a fine display, and some sorts, such as Albion and Ida Pfeiffer, striped; Marie d'Ecosse and Mammoth, white; and Prince of Wales, blue, were very effective. Collections also came from Mr. Macintosh, Hummersmith, Mr. Young, and Mr. Bartlett, to each of which a prize was awarded.

Of Lilies of the Valley good pots came from Mr. W. Paul, Mr. Bartlett, and Messrs. Cutbush; and Chinese Primulas from Mr. Todman, gardener to R. Hudson, Esq., and Mr. Fountain, gardener to Miss Wood, Ealing. There were also several miscellaneous collections of Hyacinths, Tulips, and other bulbs from the above exhibitors.

Beautiful groups of Roses were furnished by Mr. W. Paul and Messrs. Paul & Son; and several boxes of cut blooms by the former. Camellias came from Messrs. Lee, Bull, and Young. For the prizes awarded we must refer our readers to our advertising columns. Respecting the Roses and the new Hyacinths some notes will be supplied by "D., Deal."

Forced shrubs were not numerous. Messrs. Cutbush had a first prize, and Mr. Young a second, for collections consisting of Guelders Rose, Rhododendron Cunninghamii, Deutzia gracilis, double-flowering Peaches, Andromeda boxifolia, Forsythia viridissima, and a Philadelphus; and Rhododendrons were furnished by Mr. W. Paul, Mr. Young, and Messrs. Cutbush, the former taking the first prize for six, and for a single specimen, a bushy well-bloomed plant of Blandyanum. The six were smaller plants of Illuminator, Atrosanguineum, Sir I. Newton, Pardolot, and Schiller. Second and third prizes were awarded to Mr. Young and Messrs. Cutbush respectively.

Greenhouse Acacias made but a small show, being only exhibited in threes, and as small plants. Messrs. Cutbush were first with A. Drummondii, eriocarpa, and grandiflora magna, with spikes an inch or more in length; and Mr. Young second with the first two and nitida.

Epacrises were only shown by three exhibitors—viz., Messrs. Lee, Cutbush, and Young, who stood in the prize list in the order in which they are named. Messrs. Lee's consisted of a large specimen plant of Eclipse, and of Ornata and Saluinea; other sorts were Copelandii, miniata splendens, and Walkerii. Hyacinthiflora, lively rose, and Sunset, crimson, in Messrs. Lee's miscellaneous collection were very pretty.

Among miscellaneous groups of plants Mr. Bull, of Chelsea, contributed different varieties of Aucubas, some in fruit and one or two in flower, Peperomia arifolia, a beautiful azure blue Ipomoea from South America, Dracenas, Yucca quadricolor, variegated Podocarpus, several pots of the showy Imantophyllum miniatum, Costas zebrinus, Arancaria glauca, Eleagnus japonicus, with well-marked yellow variegated foliage, Bigonia viscescens argyrea, with leaves variegated with white, and with violet in their young state, the handsome Bertolonia margaritata, Lomaria gibba, and Azalea punctulata, which has sported into two other forms; also, twelve Orange trees in pots, forming handsome little standards, bearing numerous fruits. Mr. Bull was awarded a first prize for his collection, and a like award was made to Messrs. Lee for a fine group, comprising Dendrobium moniliforme and noble, ten Aeonias bearing an abundance of their bright red berries, Ixora Griffithii, in excellent bloom, Epacrises, Azaleas, Camellias, and Hedera fuchsoides, in good bloom. Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, sent a well-grown specimen of Chorozema Lawrenceanum, exhibited at the previous weekly show, Azaleas,

Cyclamens, &c.; E. J. Graham, Esq., his large and very fragrant Violet Czar; and Mr. Bartlett, Todea pellucida, and other Ferns, and a miscellaneous collection of plants in flower. Mrs. Mitchell, Anglesea Terrace, Battersea, exhibited wax flowers creditably executed, consisting of Gloire de Dijon and other Roses, Camellias, &c.

Mr. Gardiner, Easington Park, Stratford-on-Avon, contributed fine specimens of Apples, grown on the blue lias clay of south Warwickshire. They consisted of Sturmer Pippin, Reineette du Canada, Hanwell Souring, Dumelow's Seedling, Yorkshire Greening, and others unnamed, and were in such excellent preservation that not a speck was to be seen on them. They had, it was stated, been kept in a dark, dry room, where an almost uniform temperature of 40° was maintained.

A number of extra prizes were awarded, for which we must refer our readers to the prize list in another column.

HORTICULTURAL SOCIETIES IN UNION WITH THE ROYAL HORTICULTURAL SOCIETY.

THE Council offer the following advantages to Provincial Horticultural and Floral Societies which may desire to enter into union with the Royal Horticultural Society:—

1. The Council will transmit free to each Society in union one copy of the "Proceedings" and "Journal" of the Royal Horticultural Society.

2. They will insert either in the "Proceedings" of the Royal Horticultural Society or in its "Journal" according to the character of the contribution, the more important notices or papers the Society in union may wish to have published.

3. They will transmit to the President of the Society in union, for the use of its members, a transferable ticket, conferring on the bearer of it the following advantages:—

a. The right of free admission to the Gardens whenever they are open.

b. The right of introducing two friends personally on any day of the week excepting on Saturday, when one only can be introduced.

c. The same right as a Fellow of purchasing tickets at a reduced rate, before the day of the show, for the great and special shows, and on the day of the show, for the Saturday weekly shows.

4. They will transmit to the President forty orders, each order giving admission to South Kensington or to Chiswick to one person.

5. They will allow to the Societies in union a two-guinea Fellow's chance in the ballot for plants for each two-guinea subscription paid.

6. They will send to the President of the Society in union for the use of its members, one share of the seeds distributed among Fellows, and will procure for the Society seeds of the best description at wholesale prices.

7. They will allow the Secretaries of the Societies in union, to procure for its members such cuttings as can be spared from Chiswick Garden.

8. They will exchange plants and seeds, &c., with the Society in union.

9. The terms of subscription are an annual payment of two guineas, but a Society may, by payment of two or more two-guinea subscriptions, obtain increased privileges in proportion to the subscription paid.

It is to be understood that the privileges are offered to the Society for subscriptions paid by it as a body, and not to individual members of it.

INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS.

IN our article last week under the above heading there was an omission or two, and there is a correction which we have to make. In the list of local committees formed in Scotland, that for Elgin and the north of Scotland has Mr. H. Rose, of Floors Castle, named as the Hon. Secretary. It should be Mr. John Webster, The Gardens, Gordon Castle, Fochabers, N.B. In the list of local secretaries the name of Robert Warner, Esq., of Broomfield, Hon. Secretary for Chehmsford and the county of Essex, was unfortunately omitted.

A very numerous and influential local committee has just been formed at Dublin, of which the Right Hon. the Lord Mayor is the Chairman, and the Hon. Local Secretary W. E. Steele, Esq., M.P., the energetic Assistant-Secretary of the Royal Horticultural Society of Ireland. We have great pleasure in recording this fact, as it manifests that a lively interest is being taken in this national movement in the great capital of the sister Island.

ROYAL HORTICULTURAL SOCIETY.—The blossom of the beautiful *Amherstia nobilis*, so rarely flowered in England, and to obtain which was the special object of a mission sent to India by the late Duke of Devonshire, will be exhibited at the meeting of the Society this day. Mr. Bateman, F.R.S. and a Vice-President of the Society, will deliver a lecture on this glorious plant.

THE ROYAL BOTANIC SOCIETY'S FIRST SPRING SHOW.—MARCH 17.

This took place on Saturday last, and was a charming display of spring flowers most effectively arranged on turf banks in the exhibition tent. In the background, along the canvas walling, were ranged *Arbutus* on the one side, specimen *Camellias* on the other; in front, *Hyacinths*, *Tulips*, *Crocuses*, and other spring bulbs; in the centre, a bank of *Roses* in all their freshness and beauty; at one end, flowering and fine foliageed stove and greenhouse plants; at the other, a group of rich-coloured *Rhododendrons*. Following so closely the show at Kensington, the subjects exhibited there were to a great extent reproduced on this occasion, and as these have been already noticed, it will be unnecessary to do more than mention their presence.

Hyacinths were numerous shown, both in special classes and in collections. In the Nurseryman's Class for twelve, Mr. W. Paul was first, with *Lord Wellington*, *King of the Blues*, *Garibaldi*, *Van Speyk*, *Koh-i-Noor*, a magnificent spike; *Maculay*, *Soldatere*, *Grand Lilas*, *Alba maxima*, *Laurens Koster*, *Garrick*, and *Ida*. Of the size and beauty of these it would be superfluous to say more than that they were characterised by the same excellence as at Kensington, and on a second inspection it even seemed enhanced. The second prize was awarded to Mr. Davies, Stanley Nursery, Old Swan, Liverpool, a new exhibitor at these shows, for a very creditable collection, in which *Von Schiller*, *Maculay*, *Grand Lilas*, and *Ida* were particularly good. *Duc de Malakoff*, *Madame Van der Hoop*, *Mont Blanc*, *Sultan's Favourite*, *Grandeur à Merveille*, *Grootvoorst*, *Laurens Koster*, and *Charles Dickens* completed the number.

In the Amateurs' Class Mr. Young, gardener to R. Barclay, Esq., Highgate, was first; Mr. Wheeler, gardener to Sir F. H. Goldsmid, Bart., Regent's Park, second; and Mrs. Young, Kentish Town, third, those from the latter being in glasses.

For six new *Hyacinths* Mr. W. Paul was first and Mr. Young second, the kinds being the same as those shown at Kensington. The former also exhibited a beautiful collection of established kinds; and others came from Mr. Young and Mr. Davies.

For eighteen *Tulips* the two exhibitors above named took a similar position in the prize list, and both furnished numerous collections in addition. Of the single kinds, *Keizerskroon*, *Yellow and White Pottebakker*, *Rose Luisante*, *Proserpine*, and *Cerise Gris de Lin* on account of its affording a change of colour, were six of the best; and to these may be added *Vermilion Brilliant*, and of doubles, *Tournefort* and its yellow variety, and *Leonardo di Vinci*, very showy, red, edged with yellow. *Lac Gris de Lin*, similar in colour to *Cerise Gris de Lin*, but double, will afford a further variety of colour. Unfortunately the day was too dull for the *Tulips* to be seen in perfection.

Of other bulbous plants fine collections of *Narcissi*, *Lilies* of the *Valley*, and *Crocuses* came from Mr. W. Paul; of *Narcissi* from Mr. Young; and of *Cyclamens* from Messrs. E. G. Henderson, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, and Mr. Wheeler. All the *Cyclamens* were in good bloom, but those from Messrs. Henderson and Wiggins were particularly so. Prizes were awarded to the three exhibitors in the order in which they are named.

Chinese Primulas in good bloom, and of good colours, were shown by Mr. Tudman, gardener to R. Hudson, Esq., and Mr. Wheeler, who were first and second; but the greatest attractions in this way were two new and remarkably fine varieties exhibited by Messrs. E. G. Henderson. One, called *Stewarti*, had flowers as large as a five-shilling piece, white, beautifully mottled and striped with purplish crimson; the other, *Mrs. Eyre Crabbe*, was smaller than *Stewarti*, but double, and the white ground suffused with pink. Both are decided acquisitions, and a great advance on older kinds.

Camellias in pots were furnished by Messrs. Lee and Mr. Bull, to whom first and second prizes were awarded. The varieties were *Fulgens nova*, *Valtevarado*, *Madame Langelier*, *Rossii*, *Alba illustrata*, *Prince Albert*, *Sarah Frost*, *Double White*, and *Marchioness of Exeter*, large deep red. Cut blooms in great beauty were furnished by Messrs. Lee, Todman, and Trussler, gardener to D. J. Kay, Esq., Huddesdon, and Young. Among the varieties seen to most advantage were *Double White*, *Fimbriata*; *Reine des Fleurs*, *Mathodina*, red; *Optima* and *Caryophylloides*, carnation-striped; *Varegata*, very showy, red, with some of the petals nearly entirely white; *Valtevarado*, rose; *Fra Arnoldo da Brescia*, rose, with a white stripe up the centre of each petal; *Countess of Orkney*, and *Lady Home's Blush*. To Messrs. Lee and Todman first prizes were awarded, Mr. Trussler and Mr. Young being second and third.

Of *Roses* in pots, though no prizes were specially offered, beautiful examples were shown by Mr. W. Paul and Messrs. Paul & Son, to each of whom a silver medal was given. Those from the former comprised *Dr. Lindley*, very rich in colour; *Senateur Vaisse*, *Elizabeth Vigneron*, *Mrs. Bouquet*, *Duchess of Sutherland*, *Madame de St. Joseph*, very full of bloom; *Victor Verdier*, and *General Jacqueminot*; whilst from the latter came *Model of Perfection*, *Maurice Bernardin*, *Louise de Savoie*, *Victor Verdier*, *Alba Rosa*, *Madame de St. Joseph*, *Beauty of Waltham*, *Princess Camille de Rohan*, *Princess Mary of Cambridge*, *President*, and others. Among novelties, *Calanthe Turneri*, pure white, with a purple eye, and *Dendrobium primulinum giganteum*, with a pale primrose lip, and lilac sepals and petals, came from Mr. Williams, of Holloway; and from Messrs. Paul & Son, *Philadelphus grandiflorus speciosissimus*, with fragrant white flowers

24 inches across; and *Diervilla multiflora*, with tubular maroon flowers, with white anthers and a long pistil, surmounted by a white stigma. Both the above appear to be acquisitions in the way of flowering shrubs. Mr. Bull again exhibited a large collection of new and rare plants, the same as that shown at Kensington, as well as handsome standard *Orange trees*, and was awarded a silver medal. Some seedling *Cinerarias* were also shown by Messrs. F. & A. Smith, of Dulwich, but the season was too early to form a definite opinion of them. Groups of flowering and fine foliageed stove and greenhouse plants from Mr. Williams, Messrs. Lee, and Mr. Wheeler, received first, second, and third prizes, and consisted of *Azaleas*, *Camellias*, *Hedera*, *Ranunculus*, *Erismatium pulchellum*, a fine flowering specimen of *Francaea confertiflora*, *Yucca aloefolia variegata*, *Draecenas*, *Cordylina indivisa*, *Pandanus javanicus variegatus*, handsome plants of *Dicksonia antarctica* and a very fine specimen of *Aloeia in metallica*, which came from Mr. Wheeler, who also exhibited half a dozen exotic Ferns. Messrs. Lee again produced their handsome fruiting *Ancubas*, Mr. W. Paul a fine group of *Rhododendrons*, and Mr. Young greenhouse *Ancubus* and forced shrubs. From the Rev. George Cheere came a pot of *Anna Boleyn Pink*; and lastly Mr. Reeves of the Ladbroke Nursery, Notting Hill, showed a dozen admirable specimens of *Dentzia gracilis*, which, though only in six-inch pots, were covered with a profusion of their pretty white flowers.

CRYSTAL PALACE SPRING FLOWER SHOW.

This was opened on Saturday, and will remain open during the present week. The flowers are from Messrs. Cutbush, of the Highgate Nurseries, and, as usual, are of very superior excellence. They are tastefully arranged on a platform at one end of the Palace aisle. We shall notice them fully next week.

AIDING IN FERTILISING BLOSSOMS.

It is a custom among gardeners to perform a work which they deem necessary—namely, fertilising or setting their *Peach* and *Nectarine* flowers, a practice which I consider useless in fine weather.

I presume the gardener considers that the pollen is carried from the anthers to the stigma by the means he uses, consequently conducing to the setting of the fruit. Do you consider such assistance really necessary? Why has nature provided pendent flowers with a longer style than those growing erect? Most assuredly that the work may be performed naturally.—INVESTIGATOR.

Precisely so; but all flowers are not pendulous, nor are all stamens and pistils of such disproportionate length. If we had the trees in a *Peach-house* in bloom in February or March, and in cold weather, and we did nothing to move the air so as to scatter the pollen, and the fruit did not set to our mind, we should blame ourselves afterwards. The cultivator must not always depend on Nature. How many of the handsomest *Cucumbers* never will produce a seed if left to themselves? How seldom do the fine flowers of the *Granadilla* set fruit without being helped? Again, how many flowers, especially those which are diocious, depend for fertilisation upon insects carrying the pollen to the female flowers?

CUCUMBER CULTURE.

The cultivation of *Cucumbers* in winter is a subject which, though very useful, is very little touched upon; for this reason I will endeavour to give a sketch of the system I adopt, and which has invariably proved successful in my hands, and with others will no doubt do the same. It is very simple. About the end of September I cut down the old plants, which have been bearing since the previous Christmas. The house then undergoes a thorough cleansing and fumigating; the walls are whitewashed with good lime and sulphur; the pipes are also painted with boiled oil, which, besides adding to the neatness of the house, keeps them from rusting. Thus cleaning the house I consider to be one of the greatest advantages to the young plants, it destroys the haunts of insects; and where do insects thrive so well as in a dirty house?

I shall now suppose the house to be clean; I will therefore proceed to detail my method of raising the young plants necessary to fill it. I have for many years used plants from cuttings in preference to those from seed, and although there is thus a little more trouble at first, it is amply repaid afterwards. I have never found the plants degenerate under this treatment, as many persons aver they will. The sort I cultivate is a black spine of my own raising, an improvement on the old Lord Kynyon's Favourite. It has always given me great satis-

faction. I believe the black-spined varieties are far superior to the white for winter cultivation, setting better, and not requiring so much sun as the white. I pot the cuttings singly in small thumb pots, and plunge these in a moderate hotbed. Great care should be exercised in shading them from the sun, and giving them air towards the evening. A moderate supply of water only should be given, otherwise they are liable to rot off. They should also be syringed occasionally.

Here we will leave them while I describe the preparation of the house. My own is a half-span, with one bed in the front about 3 feet deep. At the bottom of the bed I place a layer of brickbats and crocks as drainage, and on this cotton-dust well saturated with water. This I find affords the necessary heat, and retains its heat well—an important point in Cucumber-growing. After allowing the cotton-dust to cool down for a day or two I put in the soil, which is composed of the soil of a meadow, taken from below the grass, mixed well with spent horse-droppings, to keep it open. This I also allow to remain for a day or so, after which the plants may be put in, providing, of course, they have prospered. Be careful to choose a dull day for the work; if not, shade them well from the sun. When well established the plants should be syringed daily with tepid rain water, if the sun is shining. This is very beneficial to the plants, it freshens the foliage, and, above all, keeps down insects. Occasional fumigations with common tobacco paper are also necessary.

Towards the beginning of February the plants will have reached the top of the house, they should then be tied down to the bottom wire, when they will start up again beautifully. Another important point to be attended to is damping the house. This should be done three times a-day, or oftener if necessary. The floor and pipes should be well watered with a rose, so as to raise a steam. Evaporating-troughs placed on the pipes, and filled two or three times a-day, will also aid this object greatly.

By persevering in the above treatment Cucumbers can be obtained from Christmas to September, or if there are two houses, all the year round.—PETER.

FLOWERS OF THE PAST SEASON.

BEDDING GERANIUMS.

FASHION—which is fast consigning florists' flowers to oblivion, and seeking to heap ridicule and contempt on those whose enthusiastic love for their favourite Tulip, Auricula, Pansy, or Carnation did so much to encourage a love of floriculture amongst a class who, without these florists' flowers, would never have thought of it—has brought into prominence and raised to the very first rank of favourites what a few years ago would have been a mere "outsider;" and the common scarlet Geranium, which was at one time considered only fit for the cottage window, is now the petted child of the first gardeners in the land. There are some of us, who sigh for the days that are past, who remember with feelings of pleasure the meetings of former times, when John Dickson of Brixton was in his glory, and Turner of Slough a "prentice hand" at those flowers of which he has since become the king of cultivators. I met one of the heroes of other days lately in a railway train, and a pleasant little chat we had over those times. He afterwards became a great Orchid fancier, and his name figured in many a prize list. We cannot, however, be out of the fashion. I question now in these days of push, and bustle, and love of novelty, whether we shall see a resuscitation of this love of florists' flowers, and so we must bend to the prevailing current.

In giving these notes on new flowers I do not pretend to give complete lists. I only speak of those I have seen either in my own garden or in that of my friend and neighbour Mr. Banks. These indeed comprise a great number, but not all of the novelties; and while not pretending to infallibility, I am inclined to think that, as far as circumstances will allow, the judgment will be found correct.

BULL.

I have repeatedly spoken of the excellent strain of Zonale Geraniums which Mr. Bull has obtained, and when his flowers become better known I am sure they will be more appreciated for their size and bedding qualities. I this year in my small garden substitute Editor for Tom Thumb and Attraction, and hope Clipper will be in the same honourable position.

Governor.—A large rich scarlet. Flowers of excellent form and substance; trusses large.

Serena.—A beautiful and attractive flower, in the style of Eve and Charmer, but superior to either of them.

Manfred.—A fine, large, and striking flower of great merit, brilliant scarlet in colour, and free in habit. I have noted this as A1.

Maiden's Blush.—A delicate beautifully coloured pink flower, and likely to be useful.

E. G. HENDERSON & SON.

Bridal Beauty.—In the style of François Desbois and other foreigners. Centre of the flower bright rosy salmon; margin pure white; colours constant. Excellent also for pot purposes.

Rose Perfection.—Light clear rose; upper petals with white centre. In the style of Rose Rendatler, &c. Medium in growth.

BALLEE.

Yvonne.—A beautiful flower. Bright scarlet with white eye. Foliage very prettily marked with a dark horseshoe, splashed with brown. I imagine this will make a very effective pot plant.

SALTMARSH.

Luna.—A fine flower of the Mrs. Milford section of Geraniums. Last season seemed to be peculiarly trying to this class, and in many cases Cloth of Gold and others of a similar character made no growth at all. Luna was more vigorous, and did well.

Little Treasure.—A very pretty dwarf-growing variety. Very free-blooming, and well adapted for small beds or for the edgings of larger ones.

F. & A. SMITH (DULWICH).

In the catalogue published by this firm there is perhaps the largest and most varied assortment of bedding Geraniums to be found, whether continental or home-grown, and hence there is every opportunity for obtaining good sorts. I am very much mistaken, from what I have seen myself, whether there are not at Dulwich some varieties of the Mrs. Pollock style, which will exceed anything as yet out. Messrs. F. & A. Smith sent out twenty-four varieties last season. It was not to be expected they would be all first-rate, but some of them are without doubt flowers of great merit; of these I think the following are the best:—

Biondella.—In the style of François Desbois, &c.; but the centre a deeper orange salmon, shaded with the same colour, and with white margin.

Conspicua.—A fine flower, of a rosy blush colour. Good form and substance.

Glow.—Well deserves its name. Truss large, individual pips very large also, measuring nearly 2 inches across, a rich deep scarlet; foliage with dark zone. An excellent flower.

Loveliness.—Colour rosy blush with salmon centre; foliage with dark zone. Good flower.

Magnum Bonum.—Orange salmon; eye light. A very large well-formed flower; trusses very large and fine.

Pre-eminet.—Somewhat in the way of Excellent as to habit, foliage, &c., but deeper in colour. An excellent variety.

Prince of Orange.—I believe this will be found to be a most useful flower. Its habit is dwarf and compact. The colour is a bright orange scarlet, and the trusses are very abundantly produced.

Premier.—Very deep scarlet; white eye. Will make an excellent plant for vases or pots.

Rev. H. Dombain.—Modesty forbids. It is, however, a rich dark cerise flower, with a shot of lake through it; flowers good and large. A very desirable variety.

G. SMITH, TOLLINGTON NURSERY.

How many good things have come from this little nursery, and how much care must have been exercised in fertilising in order to procure so many! Of the Geraniums Mr. Smith sent out last year two struck me as very good, and one as being but a little behind them.

Glory.—Flowers of a bright orange scarlet, in the way of that well-known and valued flower Herald of Spring, but its colour is even brighter than that. The individual pips are very large, and the truss fine.

Highgate Rival.—Rosy salmon; truss large; flowers well shaped. Very free bloomer.

Princess.—Bright rosy pink; truss large. Promises to be a good bedding variety.

It will be perceived that I have not mentioned any Nosegay varieties, for I cannot as yet school myself to admire them. I admit that many of them are brilliant in colour, and that there are, moreover, tints in them that have not as yet been obtained in the Zonale section; but I have never yet seen a bed even of Stella or Cybister that pleased me when I came to close quarters, however brilliant at a distance. The

centre of each truss dies off first, leaving a blank space, and giving a very dingy look to the bed. While the process of cross-fertilisation is gradually introducing into the *Zonale* section the desired tints, I may be behind the age in preferring symmetry to raggedness, but I really cannot help it.—D., *Deal*.

THE AMATEUR'S AND COTTAGER'S FORCING PIT, AND PIT FOR GENERAL PURPOSES.

I HAVE sometimes obtained the character of a retrogressionist, because in these days of heating by hot water I have now and then had a good word to say for brick and iron stoves, and the old-fashioned stoves, as the cheapest at first and by far the most economical afterwards for heating small places. I am fully aware of the pleasant and safe heat obtained from hot water with means of evaporation at command; and I believe that there is no other mode so economical when several houses and pits have to be heated from one boiler, as then there is only one chimney to take away the heat unappropriated by the water; but in all such cases of economy there is always the risk of the one boiler giving way at a critical time, when all the houses heated from it might be greatly injured before the boiler could be repaired or a fresh one substituted for that which is faulty. Then, on the other hand, when a boiler heats only one or two small houses there will always be a waste of heat up the chimney unless there is a longish flue, no matter how careful you are with the damper and the ashpit-door, and that due carefulness will rarely be exercised unless by the person who has the strongest reasons for doing all this in the best and most economical way. After considerable practice I have come to the conclusion, that for keeping frost out of a small house where a temperature of not more than 40° or 45° is required in cold weather, nothing beats a well-built brick stove, fed either inside the house or from an opening outside the wall; and where a higher and more regular heat is wanted in a small place, then I conclude that nothing for first economy and future economy in fuel will compare with a small well-built flue.

In former volumes I have several times alluded to the many things that farmers might grow from the heat of the manure and litter in their yards, and amongst the rest have instanced Cucumbers, as there would almost always be plenty of fermenting material to apply as linings to either frame or pit to keep up the requisite temperature. Influenced by such remarks from myself and other friends, many artisans, mechanics, and the better-to-do labourers, have bought their two, three, or more loads of farmyard dung, prepared it properly for a Cucumber-bed, and placed a frame over it, finding that the manure paid itself well when ultimately transferred to the garden or the allotment. Many, however, failed to succeed with Cucumbers according to their wish, because they began too early, and, though they obtained enough of heat at first, they could not afterwards afford manure to keep up the heat by linings. Those who can obtain only a load or two of fermenting manure should be content to put the most of that underground, set the frame on it, and plant out in May, depending chiefly on sun heat after the plants are fairly in growth; but then, if disposed to sell, much less in comparison will be obtained for the fruit than if it were produced in May and June. This difficulty in obtaining fermenting material, and the additional trouble in preparing and watching it to secure a regular heat, have led some of our enthusiastic amateurs among our artisans and tradesmen to try other modes of effecting their object.

For many years the most successful in cutting early Cucumbers among unprofessionals in this immediate neighbourhood has been Mr. Attwood, boot and shoe maker, in the pretty village of Lilley, four and a half miles from Luton and Hitchin. As there are now the Messrs. Attwood, father and son, and both equally enthusiastic in gardening, it need not be wondered at that the garden is a picture of neatness and good taste. Until about three years ago Mr. Attwood used the old-fashioned frames for his Cucumbers. Never have I met with a better example of the rest and the zest which are obtained, not from doing nothing, but merely from a change of labour, every run out from the seat to the frames, or a short spell in the garden, imparting fresh vigour for prosecuting the regular professional work. In the gloamings from autumn to spring—those witching moments of the twilight between the fading of the light of day and the lighting of the lamp, in which so many of us like to indulge in a quiet dreamy mood—again and again

have I met Mr. Attwood with barrow or bag, scouring the roads and lanes, collecting withered grass and tree leaves to add to his valuable fermenting heap. These sources of supply gradually became more meagre, the collecting of them more laborious, the purchasing of fermenting material more precarious, and little to be depended on; and it became apparent that a pleasant and a profitable hobby must be given up, or other means of obtaining heat resorted to, and what I call the model pit for such amateurs was the consequence.

This pit, 5 feet in width and 25 feet long, outside measure, is a very neat-looking affair, and was built and is worked very economically. I dare not say how much, or rather how little it cost, as with the exception of the flues and the tanks of Portland cement on the top of the flues, the work was mostly done by Mr. Attwood, junior. During the heating season, the cost for fuel is from 1s. to 1s. 3d. per week, and Cucumbers are generally turned out about the beginning of March. There had also been a collecting of brickbats and old bricks for some time previously, but all the flues and part of the walls were new bricks, purchased at the market price. The simplicity of everything secures the first and ultimate economy.

I shall now describe this useful pit as it stands, of which the figure is a cross section, and drawn roughly to a scale of 4 feet to the inch.

1, Is the bottom of the pit, formed of brickbats, stones, &c.

2, Back wall of pit, 3 feet 8 inches in height, 2 feet 4 inches above the ground level (9). This wall is formed of single bricks on bed—that is, 4½ inches wide, or nearly so, bound with a wood plate at top of the same width.

3, Front wall built in the same way, 3 feet 4 inches in height, and 2 feet above the ground level.

4, 4, Flues along the front, round the farther end, and along the back to a small chimney. These flues can scarcely be more simple or substantial. Suppose on the floor of the pit, close to the furnace end of the front wall, you level a space 10 inches wide all the way round to the furnace end of the back wall; or, if you choose, in that length of 55 feet or thereabouts, you make your level, so that at the furnace end of the back wall the level will be 2 or 3 inches higher than where you began, though if all is a dead level it will do well enough—on this level place a layer in mortar of brick on bed—that is, 9 inches wide, which will form the bottom of your flue. Then on each side of this nine-inch base set, with good mortar, a brick on its side—that is, 4½ inches deep, connect these crosswise with another brick on bed, with good mortar between the joints, and your flue is made, leaving a hollow space for the heated air of from 4 to 4½ inches wide and the same in depth, which is amply sufficient to secure from 70 to 80° even in cold weather. You will perceive that the base and the sides of the flue abut against the outside 4½-inch walls, and

5, 5, The inside walls, which are built with brick on edge—that is, 2½ inches wide, with a couple of wider piers in the length; but the walls have stood very well.

6, Shows a little hot dung, put in the bottom of the pit to help to heat the soil sooner.

7, Is 18 inches deep of soil for the Cucumbers.

8, Represents small spars of lath that go across the openings between the walls to prevent the vines of the Cucumbers falling down. It has been noticed that Cucumbers that hang down above the flues grow more quickly and straighter than those on the bed; but for the slight expense of a trellis right across, we would have it, and have the earth in the bed lower to permit of it.

9, 9, Is the general outside level of the ground, which permits of work being done easily either from the back or front of the pit.

A few supplementary remarks may here be added.

First, The stoekhole is sunk at the end and covered with a flap door, and is sufficiently low to permit the furnace-bars of

the small furnace being some 18 inches below the bottom of the flue.

Second, The flue, though so small, would give out far too much heat at the furnace end, and, therefore, for 6 or 8 feet the brick covering is double instead of single, and for about 3 feet, I believe, the thickness is about triple brick on bed.

Third, In front especially, there are at least three large cisterns, or evaporating-basins, formed by plastering with Portland cement the top of the flue, the side walls, and the bricks across to make the cisterns, which stand well, give off abundance of vapour, and supply hot water for watering and syringing.

Fourth, The bed 7 is 2 feet in width, a width which, as I have often stated, will render Cucumbers more fertile than if the roots revelled in the five-foot width. The hot dung at the bottom will help to heat the soil when first put in; but not to be troubled with such dung at all, some rough stones might be placed in the bottom, and openings left in the walls 3, 5, opposite the flues; but even without that the flues would soon heat the soil, as now arranged, if the bags and cloths used for covering the glass were placed along the latticed parts 8, 8, as then the heat from the flues would tell more on the bed. If cold soil is now put in, it generally becomes hot enough in eight days.

Fifth, Along the length of the flue there are five or six openings left in the brick covering, and on these a paving tile is fixed above the level of the bricks. By moving of these tiles, the flue can be rapidly cleaned without disturbing any part except these tiles. It is always cleaned before commencing Cucumber work, and the exposed portions of the flue are washed with fresh lime. All the walls are washed with lime and sulphur, also, before commencing forcing-work.

Sixth, It will be easily seen how such a pit, with shelves or without them, might be used with the least or with more heat to keep plants for bedding, &c., in winter before commencing with Cucumbers or Melons.

Seventh, Some improvements might be suggested, such as, for early forcing, having a few pipes along the front, one end opening above the flue, and the other communicating with the air outside above the surface level, and furnished with a plug to let air in or not at pleasure. The flue along the back will enable air to be given early by tilting the sashes there. Until the season is advanced Mr. Attwood uses covering for the glass at night. This keeps the heat from the flue more genial.

Eighth, Along the front of the pit outside a young Vine is trained, which, in addition to the sun heat, was no doubt much helped by the wall being heated by the flue inside, so that some fine bunches were produced. Like a good many of us gardeners, who will not let well alone, Mr. Attwood thinks of taking a part of the Vine inside, so as to have early Grapes; but of course if he do so he must lose so much space for Cucumbers. He might have fine Grapes when the wall is covered with the Vine, by having a moveable small glazed box placed against the wall, as indicated by dots (10), and to have them early, half a dozen or a dozen half-bricks in the length of the wall might be moveable, to admit when open the heated air to the Vines. There would not, however, be the same easy access to the Cucumbers.

Ninth, I by no means infer that there is much of the novel in this neat little pit, but I think it will be interesting to amateurs, among tradesmen and artisans especially, from its being built and successfully managed by one of their own class, just on the principle that what is done by one, others may at least try to accomplish. Let it not, however, be supposed for a moment that the possession of such a pit will ensure success unless to its possession there be added, not only practical skill, but unremitting attention.—R. F.

CULTURE OF VINES IN POTS.

Judging from the frequency of the applications for information on the management of Vines in pots, it would appear that the culture of fruit trees, and especially of Vines in pots, is not losing but gaining ground. Though Vines have been grown in pots for the greater part of a century, it is only of late years that this mode of cultivation has been generally practised. Now, in almost every garden they are grown more or less extensively; and this has created such a demand for what are known as fruiting Vines, that the supply is barely equal to the demand. Only a few years ago the propagation of Vines for sale was limited to those for planting out; but now we find them grown by the thousand, more for fruiting in pots than for planting new or replanting old vineries. It is by no means

uncommon to meet with thousands of Vines at our principal nurseries, and yet we are told that great as the supply is it is hardly equal to the demand. Partly for the latter reason, partly from the oft-repeated applications for information, and partly for the supposed reason that many like to raise and grow their own Vines for fruiting in pots, and derive as much if not more gratification from doing so as from fruiting them, I am induced to offer some hints on the cultivation of Vines in pots. At the same time I hope that others will also state their experience on this subject.

In propagating from eyes select the most plump eyes upon a cane of the previous year, as thick as the little finger, and brown and hard, showing that the wood has been well ripened. Reject all canes of which the eyes are large and flat, or have the appearance of being double, and more particularly all canes as thick as the thumb, and not well ripened. The wood from which the eyes are taken should be kept from the time of pruning to that of inserting the eyes with the lower end in moderately moist soil, in a house from which frost is excluded. Take care to use no eyes but those from Vines which have not been affected by thrips, red spider, or mildew in the previous year, as the leaves, being robbed of their juices by these pests, can only form imperfect buds at their axils. In preparing the eyes proceed as follows:—Having fixed on one, place the edge of a sharp knife behind where the tendril was, and where the wood is slightly raised make a clean cut through the cane in a slanting direction, so as to bring it out three-quarters of an inch below the eye, and on the same side as that on which the eye is situated. Turn the cane upside down, and make another slanting cut nearly from the same point as the first, but beginning it one-eighth of an inch higher up, and bring the knife out three-quarters of an inch above the eye. The eye thus prepared will measure 1½ inch from cut to cut on the upper side, and be exactly of the form shown in the engraving.

For potting the eyes prepare the pots by placing a piece of pot or crock over the hole, then an inch of smaller pieces, and upon these half an inch or so of the siftings of the soil. Fill the pots to within half an inch of the rim with soil chopped pretty fine with a spade, but not sifted; and a portion of the soil should be sifted through a sieve with quarter-inch meshes, which will give fine soil for covering the eyes, and rough pieces to put at the bottom of the pots over the drainage. The pots should not be less than 3 nor more than 4½ inches in diameter, and the soil should have no manure in it, but be turfy light loam from turves a year old.

In potting place the eye in the centre of the pot, flat, and pointing upwards, and press it in so that the cut part may be imbedded. Now cover the eye, or fill the pot level with the rim, with the finely sifted soil. Passing the thumb round the inside of the pot will lower the soil half an inch or so there, leaving the centre elevated over the eye. If the soil is in the right state no water will be necessary, but if dry give a little round the thumb mark inside the pot, which will keep the water away from the eye, or not wet the soil much over it.

After potting plunge the pots to the rim in a bottom heat of 55° for a fortnight, and that temperature must not be the reading of a thermometer at 1 foot below the surface, but at 2 inches below it, for it is there that the eyes are. Keep them plunged until they raise the soil over them, which will be in a fortnight, or at latest in three weeks, then transfer them to a bottom heat of 75° at 2 inches below the surface. If plunged in a tan-bed it must have a temperature of 90° at 1 foot below the surface, to give one of 75° at 2 inches beneath it; if a dung-bed covered with soil and dry, 85°, and if the soil be wet, 80°. The temperature where the eyes are situated should in any case be 75°. The top heat should be 65° by night. In this heat, top and bottom, the shoots will soon appear, and then the surface of the pots ought to be sprinkled through a syringe, morning and evening, with water of the same temperature as that of the house, causing the water to fall upon them like a fine but thick mist. This will generally keep the soil sufficiently moist; if not, give water so as to keep it moist, but not wet, otherwise the eyes may only give a shoot which will rot off, and, on the other hand, if dust dry the eye will show growth only to the extent of an inch or two, and then be dry and withered.

When the eyes have rooted and made growth alike at top and bottom, and the pots are full of roots, bring into the house a quantity of soil sufficient for shifting them into larger pots, and keep it there two or three days and nights to air. The pots I now propose to give are 6 inches in diameter, and only one piece of rock should be placed over the hole, and then half an inch of the fibrous parts of the soil, and over this sprinkle as much soot as the thumb and two fingers will take out of a flower-pot. This is to keep worms from coming through the hole at the bottom of the pot, for I find them very troublesome in this respect when the pots are plunged in tan-beds.

The following is the soil which I prefer to all others for Vines in pots:—From a piece of old sward where the soil is hazel or yellow loam, and the subsoil gravel, take off the turf 3 inches thick, and lay it up in an open situation, grass side downwards. On this place a layer of fresh horse-droppings 3 inches thick, without straw, another of sods, and so on to the top of the heap. If sheep-droppings can be had, use a layer of them an inch thick in preference to horse-droppings. Let the heap lie six months, and then turn it over in dry weather, chopping it roughly with a spade, and sprinkling over it in the turning a bushel of soot to every cartload. Allow the whole to remain three months longer, and then turn it again when the weather is dry and frosty. In three months more the dung will have been mostly washed into the sods, or there will be very little of it to be seen, and what there is not the heavy, soapy mass, such as we have from manure rotted by itself. If soil of the above description cannot be procured, as a substitute collect from any wayside or place where the hedges are thin from being choked at bottom, as many tufts of grass as possible, and not only take the tufts but their roots, and an inch or two of soil along with them. Pile the tufts up, mixing with every cartload half a bushel of salt, and the same of lime. These materials should be left six months, and ought then to be turned over, adding half-redneed horsedung, such as that from an old Mushroom-bed, equal in quantity to one-sixth of the whole. This mixture, turned over again in three months, will at the end of three more constitute a compost that will grow Vines well. Failing the above composts, throw up in spring some good, rather light soil, in alternate layers, with an equal thickness of fresh dung; after being twice turned the mixture will be soil of fine quality for Vines. If the compost is naturally full of fine sandy particles no further addition of sand will be necessary; but if the soil is of a heavy nature, sufficient should be added to bring it to the state of a rather sandy soil.

A quantity of the compost being taken into the house where the Vines are, to warm, and the pots being in readiness, turn out the plants, and, after removing the old drainage, place them in the fresh pots, but without taking them out of the house. Pot the plants an inch deeper than they were before, press the soil gently, though not very firmly, about the ball, which is not to be disturbed, and give a gentle watering, plunging the pots at once in the hotbed as before. Sprinkle them overhead twice daily, morning and evening, with water, which must always be of the same temperature as the house, whether used for syringing or watering.

It sometimes happens that two shoots come from the eye. Take away the weakest with the point of a sharp knife; and if there is a show for fruit, remove it in like manner, in both cases early. The plants, being kept in the hotbed, will quickly fill the pots with roots, and begin to spindle up weakly enough. Endeavour to avoid this by affording them all the light possible, and air on all favourable occasions, maintaining a temperature of 65° by night and 70° by day, with a rise to 80° or 85° on cloudy days with clear intervals, and to 85° or 90° on those which are clear, air being given in proportion to the increase in temperature.

When the pots are full of roots repot the Vines at once into nine-inch pots, plunging them for a time, or until the roots reach the sides of the pot; then withdraw the latter by degrees from the plunging material, and finally remove them to a house where they have abundance of light and are not far from the glass. If there is room in the place or house where the eyes were raised, do not shift them out of it, but continue them in the bed. After the canes begin to run a neat stick should be placed by each, a small one at first, and a stronger one afterwards, and the shoots tied to it loosely. I do not approve of keeping the canes trained to upright stakes the first season, for it tends to render them weak at bottom, and the eyes there are poor, and the shoots that proceed from them in the following year fruitless, or productive of very small bunches. I do not consider that the canes ought to be kept trained erect after

the Vines are put in their fruiting pots. The canes after their last potting should be trained to the roof of a light well-ventilated structure, having the requisite heat, and at a distance of not exceeding 15 inches, nor less than 9 inches from the glass.—G. ABBEY.

(To be continued.)

AMOUNT OF SAP LOST BY A VINE BY BLEEDING.

An experiment I tried with a Vine twelve months ago may be deemed of sufficient interest to be allowed a corner in the *JOURNAL OF HORTICULTURE*, as showing that Vine-cultivators need not be very nervous if a little bleeding do occur at starting-time, owing to late pruning or other causes, although it may be, and no doubt is, a advisable by proper management to prevent such a waste of sap altogether.

The Vine was a Tokay, the roots of which were in an outside border. It had been planted sixteen years, and had to be dispensed with to liberate its rafter for another Vine growing in the inside pit. It was cut close to the bend below the bottom of the rafter, leaving one spur, on the 7th of April, 1865, at 10 P.M.

April	8th, 10 P.M., the Vine had bled	Ozs. Drs.

		or, 6 lbs. 9½ ozs.

During the first day or two the sap came perfectly bright and insipid; afterwards gradually more turbid, especially as the diminution became considerable towards its cessation, surrounding and sealing the wound with a mucilaginous or starchy deposit. Then the Vine quickly developed embryo buds in its old stem, throwing out strong and vigorous shoots, and, when these were removed, others with surprising persistence; and when all within reach were cut away, others followed from the lowest parts of the stem to the very end of the growing season, and the Vine is now, probably, waiting the return of warmth to renew its efforts.—THOMAS WILSON, *Thornton-in-Craven*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHILE the present favourable weather continues the principal sowings of summer crops will be completed in most localities, and there will be more time to attend to hoeing, surface-stirring, and earthing-up amongst advancing crops. The pulverisation of the soil is one of the best preservatives against the effects of frost. *Beet*, make a small sowing of Red *Broccoli*, trench ground where this crop and Brussels Sprouts are past use. The former cut, and the latter where not picked running to seed, pull up the stalks and lay them regularly over the whole surface of the ground, then spread a few barrow-loads of hot lime over them previous to their being trenched into the ground, it will kill snails and hasten decomposition. Sow Grange's Early White and Early Purple *Broccoli*, and Brussels Sprouts. *Carrots* in frames, thin out. Attend to the pricking out of all seedling vegetables sown in boxes. See that birds do not take the seeds of any of the Cabbage tribe just as they are vegetating. Pieces of glass on a string between stakes are rattled by the wind and glitter in the sun, and are a means of scaring them. *Jerusalem Artichokes*, plantations of these and Horseradish should be completed with the least possible delay. *Peas*, sow these and Broad Beans for succession, together with *Spinach*. Advancing crops of Peas should be shaded from the effects of the sun on frosty mornings, the earth to be kept well pulverised and drawn up to them as they advance. *Potatoes*, if any of the early crop are peeping above ground they had better have a little soil drawn over them, or be otherwise protected. Continue planting. *Savoy*s sow, also *Chou de Milan* and *Scotch Kale* for early winter supply. Successions of *salads* of all kinds must be kept up, and those advancing thinned out. The backwardness of the season will enable us to perform many operations which, generally speak-

ing, ought to be completed before this, such as making fresh beds of Rhubarb and Sea-kale.

FRUIT GARDEN.

Apricot blossoms are now fast expanding, and, of course, protection must be afforded in time. Coverings not intended to be often removed should be light and airy, thick heavy material must be so arranged as to be removed in all seasonable weather. Where it is intended to head-down old trees for grafting, this should be done at once, and young stock should be grafted as speedily as circumstances will admit. Finish the root-pruning of all luxuriant trees. Most persons will have observed the effect of moving a large Pear tree very late in the spring, it generally becomes covered with blossom-buds. Such may be the effect of root-pruning at this period. Strawberry-beds should be dressed, remove all dead leaves and superfluous runners, and stir the surface of the soil. Make up all vacancies in the young plantations of Strawberries put in in the autumn. Fresh beds may also be planted if required.

FLOWER GARDEN.

See that rolling, mowing, &c., proceed in due order. Now is the period for laying the foundation of a fine lawn. Provided the weather is not too frosty, let all fresh turfing be completed forthwith. It is a good plan to scatter old tan thickly over fresh-laid turf as a screen from the sun until the roots take hold. Occasional waterings are also essential. Cut all coarse evergreens and shrubs before the bud becomes too much advanced. This is a good time to cut in Holly hedges. Overgrown herbaceous plants may still be divided, the exterior portions of the stools should be reserved and the interior rejected. Planting done after this time will require much attention in watering, and this at the very busiest season of the year, especially if large plants are removed, and it is too common a practice to put off such work to the last. Look over beds planted with bulbs, and where necessary stir the surface soil so as to keep it open and friable, and also to give it a fresh appearance. Auriculas and Polyanthus will now require particular attention. Air must be admitted daily and freely. Watch the trusses as they appear, and pinch off all the weak ones, for if it is desired to have them strong and in full perfection, only one flower-stem should be allowed to remain. Stir the surface of the Tulip-beds, and give some occasional waterings during dry weather with manure water. The Tulip delights in abundant waterings, unless the soil be naturally wet and stiff. Stir the surface of Pansy, Pink, and Carnation-beds. Keep a good look-out after mice, slugs, and wireworms. Take advantage of the present state of the ground to stir the surface soil of shrubbery borders, to prevent the growth of weeds and give the whole a fresh and clean appearance. Do not neglect to put in plenty of Mignonette, and if not already done, hardy annuals should be sown without further delay, except in cases where they are wanted to bloom in the autumn.

GREENHOUSE AND CONSERVATORY.

Climbers in the conservatory will soon want frequent attention. Prune off all superfluous shoots, stop or pinch the tops of luxuriant leaders, in order to induce a flowering habit in those which produce blossoms from the axils of their leaves, and keep them neatly tied and trained. Many conservatories are unfit places for Heaths, being generally too lofty, and kept too warm for them. Some of the winter-flowering varieties are, however, very ornamental, and should be largely employed in other decoration during the spring months. As soon as they have done flowering let them be pruned back, and give them a liberal shift when they start into growth, using good fibry peat for the purpose, and if they are well attended to during the growing season, they will overcome any injury they may have sustained, though occupying an unsuitable position while in bloom. Azaleas, Camellias, Roses, early-flowering New Holland plants, and forced bulbs will keep show-houses gay for some time yet. Let all plants be placed in the best possible position as regards effect, and aim at maintaining a pleasing variety of arrangement, and displaying the colours to the greatest advantage. Pick off decaying flowers and leaves. In greenhouses keep up a lively circulation of air all the early part of the day, and dispense with fire heat as much as possible. Make a sowing of tender annuals if not already done. Pot off Balsams and Cockscombs, &c. These, however, will do better by far in a frame, with fermenting material, close to the glass, well matted up at night.

STOVE.

Attend to shifting, watering, and maintaining a free circulation of air. Continue to cut down, disroot, and repot

such plants as have been flowering through the winter. These would be better removed to a bottom heat of 80° in some spare pit or frame, and shaded. Follow up shifting, top-dressing, &c., of Orchids. All Orchids that have commenced growing and require potting should be attended to forthwith. This is a good time to shake out and repot *Cyrtopodiums*; they thrive best in good-sized pots, well drained, in a compost of equal parts good turfy peat, loam, leaf mould, creaks, and charcoal, broken rather small, mixed well together, and when the plants are growing freely they must be well supplied with water. Treat in like manner *Sobralias*, and give them abundance of water both at the top and bottom when growing freely. Pot in the same compost, omitting the loam, the following genera:—*Houlletia*, *Acanthophippium*, *Mormodes*, *Lycaste*, *Cycnoches*, *Catasetum*, and *Hundleya*. This is also the best time for parting and shifting *Gongoras*, *Brassias*, and *Acropas*; they succeed well either in baskets or pots, and should be potted rather high in sphagnum moss, with a few large lumps of charcoal built in amongst it in the process of potting, and all made fast with a few deal pegs. Look well after those noble plants, the species of *Saccolabium*, *Vanda*, *Aërides*, *Camarotis*, and such like, and as soon as their bloom-scapes have fairly burst through the leaves—say one inch long, they will be greatly benefited by plunging them in a tub of water until they are quite saturated; after this the judicious use of the syringe will be of great service to them. Continue to withhold water from *Oncidiums*, except such as are making new leaf-shoots. The general collection of Orchids will now enjoy a good steaming every clear morning for about half an hour; this may be done by sprinkling the pipes or flues when they are warm, and must be done before the fire is banked down. *Vandas*, *Aërides*, and all such plants are increased by merely cutting off a branch having one or more roots. Advantage should be taken of solar heat at all times. Take care that the air admitted to the plants is mild, that all water applied to the plants is warm, and that all plants not clean be washed.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

DURING the past week we have had cold north winds, with bright bursts of sunshine during the day, followed by sharp frost in the following night and morning, sufficiently severe to make short work of anything at all tender that was not duly protected. Rain, hail, sleet, and snow have come duly in their turns. After the mild winter, it is fortunate that the cold has come in the beginning rather in the end of the month, as then almost everything would have been greatly injured. As it is, not many hardy things are sufficiently forward to be hurt much as yet. Unless the weather change soon we shall have a late spring; and the pastures are looking bleak and bare, but even after a cold March it is amazing how fast everything grows in a fine mild April.

In the frosty mornings wheeled manure and compost for the kitchen garden and pleasure grounds from carefully-preserved rubbish-heaps, old hotbeds, &c., and as we are deficient in all fermenting material, saved every bit that would produce heat when mixed again with fresh manure or fresh-collected tree leaves. Dug and trenched ground, and turned over soil-heaps that had not been collected and built in narrow stacks, to which we never give any turning.

When such stacks can be made of turf, a sufficient amount of air can pass through them to sweeten them, and allow them to slowly decompose, and if at all large, the same object can be attained by running open drain-tiles through them, or some well-tied bush faggots. If not more than from 2½ to 3 or 3½ feet wide they will not need such care, and if topped up with a ridge, span-roofed fashion, all the rain that falls will never injure them. All the centre will be nice and dry, well aired, and fibry, ready to cut down for potting, &c., when wanted, after it has stood a year. The turning over such stacks would merely waste the fibre, and render the whole heap likely to be permeated by rain. Kept as a nice ridged heap we can have dry soil without resorting to much shed-room. It is always best to collect such turfy soil when it is dry.

Out-door Cropping.—Notwithstanding hail and snow, the frosty nights and mornings, with sharp winds and bright sun, have dried the drenched ground amazingly, and enabled us to put out a good piece of early Potatoes in good order, and to sow early Peas, Beans, Spinach, and Radishes in the open air. The ground was wetter for Peas than we like, but covered

them over with burnt earth and furnace ashes, the latter acting, too, as a preventive to a certain extent against mice and birds. Whenever there is a hole made by a bird, we shall run a string or thread along the row a few inches above it. Turned over the upper spit of ridges intended for Carrots, Parsnips, &c. Took up a lot of Celery, and set it close among earth and furnace ashes, after putting a little earth to the roots and watering it, in order that we might trench and ridge the ground crosswise, so as to make the dung from the Celery-beds go equally over the ground as preparatory for Onions. It would be of no use sowing early in such weather. Onion seed will stand almost any amount of cold, and young Onions, when fairly up and established, are anything but tender; but many Onion-beds prove failures from a severe frost attacking them when the seeds have pushed from half an inch to an inch. Prepared a border for sowing vegetable seeds, and for Turnips out of doors as soon as it becomes milder. It is of little use just now, as, after the Turnips are up, a very little frost will so injure them as to cause them to spend their energies in throwing up flower-stems, instead of making nice juicy tubers.

Planted *Potatoes* in an earth-pit, covered with old patched sashes, as alluded to last week. There will be very little heat from a few leaves below the *Potatoes*. Until the *Radishes* are fairly up, and the *Potatoes* appearing, will take all the help from sun heat possible to warm the soil, and, therefore, give little or no aid, and throw a little clean litter over the glass at night to keep the heat accumulated from radiating away again. In the case of early *Potatoes* in frames, removed the pots and tiles off other things placed temporarily between the rows that the sun might act more freely on the soil. Such intruders do little harm until the *Potato* tops are from 6 to 8 inches long. When ours grow as much as 12 inches, we often nip out the terminal bud, which does nothing to check growth, and yet keeps the plants more dwarf and bushy.

Double Cropping.—The making the most of every inch under glass, by temporary or intermediate crops, is not all gain, as much of what is obtained in room is wasted in extra labour in moving, and the head of the gardener is kept constantly at work in contriving that all this moving shall be done to the best advantage. In other cases double cropping is not all gain, there are disadvantages to counterbalance the profits. For instance, we generally have a nice supply of *Radishes* from an early *Carrot*-bed. These *Radishes* in alternate rows with the *Carrots* have been good for some time, and do not yet interfere with the *Carrots* farther than this, that to keep the tops of the *Radishes* short and stumpy, and near the root, we are obliged to give more air than we otherwise would give to the *Carrots*, and thus, for the sake of the *Radishes*, we cannot take the help we might from the sun to hurry on the *Carrots* for pulling, and few luxuries beat a sweet, nice crisp *Horn*, or early *Dutch Carrot* as thick as your thumb and not so long. It is hardly possible to have every advantage by any one system of operations.

We have a lot of *Peas* and *Beans* in tiles and boxes, which we shall keep under protection a little longer before turning them out in the open ground. There are sad complaints of autumn-sown *Peas* in some places being injured and destroyed. For *Sea-kale*, *Rhubarb*, *French Beans*, &c., see last and previous week.

Cucumbers—Pits versus Frames.—Though we like brick pits heated or not heated, we have still a lingering partiality for the old-fashioned frames. They are easily moved from place to place, and are never much out of employment. We also have a weakness in liking them for hotbeds; and one advantage they have over a fixed pit is, that by the level of your bed on which the frame stands you can place the glass frame at an angle so as to command the greatest amount of sunlight. Our partiality for them, not yet quite gone, may be owing to the fact that in our young days we were nearly as successful in obtaining early *Cucumbers* and *Melons* from such hotbed frames as ever we have been in pits heated by hot water, unless, indeed, in the midwinter months. Our earliest *Cucumbers* are in a small pit. We could not well take up more room in the pit, owing to a crop of *Kidney Beans* producing freely; and for the purpose of giving more room in the meantime, we planted out in a frame, as stated the other week, strong plants showing fruit. The bottom heat was about 80°, the top heat at night a little above 60°, and we allowed a good rise from sunshine, and the plants were going on capitally; but one morning on uncovering, our partiality for hotbeds and frames received a damper. Several large holes were seen in the bed, earth was thrown over the leaves, part of the leaves were eaten,

and every little fruit and stem of the plants was cut and gnawed, seemingly more for mischief than for food. We laid the blame to rats; but after borrowing a ferret we found none about that bed, but half a dozen huge barn and grass mice, finding, however, some rats elsewhere. We could not expect the plants to do any more good, and it is fortunate they were not the earliest; and even now we fear to turn out other strong plants, in case they should share the same fate, before we continue a course of trapping and poisoning, &c.

One drawback to the use of hotbeds and frames is, that the bed and the litter form such attractive nesting places for all such vermin. The other evening we looked over the fence into a little wood before roosting-time for the pheasants; and to our surprise and consternation, there were numbers of rats feeding close to the pheasants. If something is not done in some districts the rats will clear everything before them, as they are said to be doing in the Highlands. They will soon be dissatisfied with merely resting and burrowing in a hotbed, or purloining the best garden produce. Last autumn we could scarcely have saved a *Pea*-pod for seed, even if we had tried our utmost. Very considerably of them, the rats let the *Peas* alone when they were nice and soft for the parlour, and even, when harder for the hall; but no sooner did they approach ripeness than up the rat mounted the sticks, and cleared out the pods at his leisure, or cut them off and carried them to his burrow. It is sad to poison, with its attendant risks and cares, and too much care cannot be taken—sad to trap, with its attendant cruelty—sad to tar and feather, or rather frizzle and tar—and then sadder still to find that the enemy in its legions shows no sign of retreating. The new comers from exhausted fields to what are to them "pastures fresh and new" are the difficulty, and to be surmounted must be encountered at a distance from the garden.

Brick-pits are so far a security that the vermin cannot so easily find a burrow beneath the bed, cannot so easily gain access through the walls, but in all pits where the sashes are lifted to give air both mice and rats will gain access by that means. Whilst in a quiet brown study at this time of year, noticing some ripe *Strawberries* on a shelf in a pit mauled apparently by mice, and the seeds on the surface of the berry nipped out, we cast our eye along the wall, and, ere we could prevent them, two mice mounted the wall and whisked in at the opening tilted up for air. Trap and poison were our only alternatives, and the difficulty is to find a bait more tempting than the little seeds of the *Strawberry*. It is rare they eat much except the seeds, but that is more than enough. When a hole is made, or half a *Strawberry* devoured, the mouse is sometimes blamed for the doings of the slug, or snail. The above occurrence, and too many like it, showed that even pits are not secure against such depredators, unless the ventilators are placed in the walls, and these again are secured by plates of fine wire or perforated zinc.

We give this prominence to such vermin in hotbeds, as from several letters we find we are not alone in our experience of the evil; and in answer to inquiries as to what else is to be done to secure against future loss, especially in frames, we may mention what we are doing, and what we intend to do. In the middle of the day, when warmest, we will remove the *Kidney Beans* in pots to another place where they will finish off their crop, and prepare the pit for *Cucumbers*, keeping *Melon* plants there too until they are a good size so as to find room for them. Then as respects frames, before we plant *Melons* or *Cucumbers* out into them, we will bank up a space of 6 inches on the slope all round the frame, where it touches the hotbed, with clay or stiff loam, kneaded and watered, and left with a smooth surface. This is to prevent any noxious smell penetrating there. Then we will smear the lower part of the frame outside, and part of the dung beneath it, with coal tar, the smell of which is disliked by mice and rats, and the touch of which, on their fur coats they detest still more. This, with watchfulness, traps always in use, and the visit of a ferret now and then to leave at least his scent behind him, is about all we can think of at present to enable us to conquer these intruders. If any of our readers can suggest something better, we and many more will be thankful.

It is of little use recommending the best friend of the gardener—a good cat, or a company of them, as if kittens are obtained in most places they disappear as they emerge from their kittenhood, and begin to be really useful. The gamekeeper knows that no animal is so easily enticed from its usual haunt to its own destruction, and acts accordingly; and poor, faithful, affectionate pussy is hung up.

FRUIT GARDEN.

Much the same as last week, which see. Shut up the orchard-house at night in this cold weather. In a lean-to house the blooms against the back wall in the most forward house are beginning to open. Those in pots in the front of the house are not yet showing colour. As soon as the sun melted the hoar frost on the glass gave plenty of air, as we have no wish to forward them; but as soon as the bloom is fully open in the first house, and the weather becomes milder, we will shut up early, and give less air to bring on the crop a little earlier. This is a safer plan and more effectual than encouraging the blooms to open early in spring. We would not have grieved if the trees were not in full bloom until towards the end of March, but they will open in spite of us. A correspondent directs our attention to the expression in this department last week, page 204—"Placed a surface-dressing of hot dung all over," &c. This should have been, "Placed a surface-dressing of rotten dung from old hotbeds all over." We would also take the opportunity of drawing attention to what was there said of covering the surface of the soil with dry earth after watering. This dry surface all over was a good preservative if the frost had been more severe, and yet the watering prevented the buds suffering from dryness at the roots. With the surface of the soil dry, and the atmosphere still and rather close, the blooms of Peach trees will stand a good deal of frost uninjured, and Apricots will stand much more in a dry air. The fine bursts of sunshine just suit the setting, swelling, and ripening fruit of Strawberries, and yet the early crops have given no reasons for dissatisfaction.

Canvas Screens.—We agree in all that Mr. Keane says, page 203, about canvas coverings, moveable at pleasure, being the best protection for tender fruit trees out of doors, and, with the exception of glass, the cheapest in the end. In a great number of gardens, however, the motto of action would seem to be "Sufficient for the day is what must be done," and therefore no end of merely temporary modes of protection must be resorted to. We allude to this matter here, however, for drawing the attention of those fortunate enough to possess such moveable canvas, to a use of them, not so much employed as it ought to be, and that is, for retarding the opening of Peach blossom on the open wall. What we have stated above as respects trees in an orchard-house, as well as many other facts, prove that the temperature of the trees against the wall is much higher in sunshine than is the atmosphere or the soil only a few feet from the wall. In a March distinguished for sunshine the buds will therefore be too forward—much too forward in general in proportion to the heat of the soil in which the roots are imbedded. The screens, therefore, should be used early, kept on during sunshine to keep the buds back, and yet allow the ground to get mellow and warm, and kept off at night and in dull cold days until the buds are so far advanced that it would not be safe to do so. This retarding will help to bring the buds into full bloom when the weather will in general be milder, and the ground more genial and warm. Canvas, unbleached calico, frigi domo, and even fine Nottingham netting, will last many years if kept for such purposes alone, and put away thoroughly dry. The first expense is the only drawback; and on this account hundreds must do their best with makeshifts, though well aware that "What is worth doing at all is worth doing well," and that a penny thus saved is often not a penny gained, but a sixpence lost.

ORNAMENTAL DEPARTMENT.

We have not room to say much here; but much of our work was a repetition of that of previous weeks. In a dry day swept and rolled the walks, which had been left a little rough from sweeping snow off them. Rolled the lawn, pruned Laurels and other shrubs. Prepared for future turfing, dug and turned beds for bedding plants, washed glass when mild and wet. Gave plenty of air when mild to cold pits. When wet washed pots. Potted Geraniums, Fuchsias, &c. Prepared soil for Begonias, and made cuttings of Lobelias, Verbenas, Geraniums, Ageratums, &c., and in a week or so will take off great quantities more, when they will stand in a slight hotbed. Pricked-off seedlings of Lobelias. Sowed lots of the tenderer annual seeds, and will leave such half-hardy plants as Marigolds, Asters, Tropæolums, Stocks, for a fortnight or three weeks longer. Our ground is too cold and wet for sowing any but the hardiest annuals out of doors; but in warm, light, dry, soils, the North American annuals may be sown, but even they will do as well if sown later. For an early display an autumn sowing is more desirable. Looked after plenty of potting and

striking material under cover, that it might be sweet and warm when used.—R. F.

COVENT GARDEN MARKET.—MARCH 17.

A FEW new Grapes, chiefly from pot Vines, have made their appearance. The market in consequence of the recent frost is not so much glutted with Greens and other out-door vegetables, and the prices of some have therefore advanced. Large quantities of the usual kinds of salading, also Artichokes, Early Frame Potatoes, &c., continue to arrive from the Continent. Pines are more plentiful, but find a ready sale at last week's quotations. The arrivals of Potatoes are large.

TRADE CATALOGUES RECEIVED.

John Salter, Versailles Nursery, William Street, Hammer-smith, W.—*Descriptive Catalogue of Chrysanthemums, Dahlias, Pæonies, Phloxes, Pyrethrums, Hardy Variegated Plants, &c.*

John Morse, Dursley, Gloucestershire.—*Catalogue of Cuttings of Dahlias, Fuchsias, Chrysanthemums, Pelargoniums, Bedding Plants, Store and Greenhouse Plants, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

FANCY PELARGONIUMS, STOPPING AND POTTING (S. G. Sadlebon).—You may stop them now, but merely take out the point of the shoots and pot them into eight-inch pots. They will not then bloom until the end of June. The cooler you keep them, and the more light and air given the finer they will be. Drain the pots well.

FERNS (M. B.).—LYCOPODIUMS covering the soil's surface beneath Ferns is not injurious to them. We have ourselves the soil so covered. It is impossible for us to be clairvoyant as to what the cost of structures would be, of the size and degree of ornament about which we have no information.

CHRYSANTHEMUM TRAINING (K. M. H.).—In "Florists' Flowers for the Many" are some directions. If you enclose five postage stamps with your directions, you can have it free by post from our office.

MATERIAL FOR COVERING FRAMES (G. C.).—I have tried almost every kind of material for this purpose, and find nothing equal to mats. They are cheap, and, with care, will last for two or three years.—G. ABBEY.

BLACK ALICANTE AND LADY DOWNE'S GRAPES.—Will some of your correspondents state the result of their experience, as to which of these two late Grapes has proved the better? My own experience leads me to favour Lady Downe's both as regards keeping-qualities and flavour. I originally intended to discard Lady Downe's and plant Black Alicante in its place, but I am at present rather doubtful as to whether it would be wise.—G. D.

SAPONARIA CALABRICA SOWING IN ROSE CIRCLES. (*A Subscriber*).—It will not injure the Roses beyond impoverishing and keeping the soil dry around them. Sand placed on the surface and pointed in would make it all the better for the Saponaria.

JAY BERRIES, SOWING. (*Idem*).—If sown now they will come up about May, and be three years before they are fit to transplant. You would cover a border much more quickly by putting in cuttings in a shady border from April to July, and keeping them moist till rooted, and afterwards well supplied with water in dry weather. Cuttings so treated will be fit for planting out in the following spring.

NEWTOWN AND PARADISE PIPPIN APPLES. (*Mary Jones*).—The Newtown Pippin is a large yellow American Apple, good alike for table and baking, but does not do well in our climate except in warm localities, and requires a wall to be first-rate. A south-west or west aspect is most suitable. The Paradise Pippin is better known as the White Paradise or Lady's Finger, its flesh is more yellow than that of the Newtown Pippin, and it is not ribbed, even obscurely, as is the Newtown.

ROSES, RAISING FROM SEED. (*Idem*).—Take some pots or pans about 9 inches in depth, drain them well, and fill to within three-quarters of an inch of the rim with rich sandy loam two-thirds, adding one-third of sandy fibry peat. The lumps should be broken, and distributed over the surface from half an inch to an inch apart, and covered with half an inch of soil. The pots or pans may be placed in a warm open situation in the open ground, plunged to the rim in cold ashes. Over the pots place a cap of wire so close as to prevent mice getting through, and so high as to allow of the plants coming up; an inch space between the soil and wire will be ample. The wire assists in keeping the soil moist, and water should likewise be given in dry weather. Some of the plants will, in all probability, make their appearance in May, if the seeds are sown at once; but very often the seed does not germinate until the following spring. When the plants have made three or four rough leaves in addition to the seed leaves, take them up carefully with the haft of a budding knife, or some such implement, pot them singly in small pots, and place in a cold frame for a few days, or in a shady situation. In three weeks or a month they may be planted out in good rich soil, and by August they will have grown strong, some of them of sufficient strength for budding. Two stocks may be budded with each seedling. These will make strong shoots in the following year, if the budding prove successful, and these, if left unpruned, will produce flowers in the following or third year. On their own roots the seedlings will not flower until the fifth or sixth year.

SLUGS, DESTROYING. (*Costris*).—We do not find any plan answer so well as strewing a little dry soot around the pots or pans, and going at night with a lantern and catching them at their meals. They are then easily destroyed. A few fresh Cabbage leaves laid down at night will be found to have slugs under them in the morning. Perseverance in either of the above plans will soon clear the place.

EMPHYLEUM TRUNCATUM LOSING THE POINTS OF ITS SHOOTS. (*A. C. C. H.*).—This arises from keeping the plants in too low a temperature. You cannot keep them too dry if the wood or shoots do not turn soft and shrivel, but water should be given to prevent this. You have kept them too dry as well as too cool, and now that moisture is given the shoots drop off at the joints. Keep them in a temperature of from 45 to 50 in winter, and not so dry as to cause the stems to become soft and shrivelled.

PLANTING CYCLAMENS. (*Idem*).—Plant the corms of Cyclamen neapolitanum in June in pots or in the open ground, and they bloom in autumn; of *C. cornu* in pots in July, and they will bloom in January, and onwards; of *C. Atkinsii* at the same time, and they will bloom in winter and early spring; of *C. persicum* in August, and again in September, and they will flower from November to April according to the temperature. Put the varieties of *C. europaeum* in spring, and they bloom in summer, and they are the sweetest of all. *C. repandum*, which blooms late in spring, should be potted in autumn. If you write us, stating more explicitly your wants, we will endeavour to meet your wishes.

GELSEMIUM SEMPERVIRENS. (*J. P. G.*).—It succeeds best trained to the pillars of a conservatory. If grown out of doors it requires to be trained against a south wall, and to be matted over in winter. Miller so cultivated it in the Botanic Garden at Chelsea. It has been called *Iignonia sempervirens*, *Anonymus sempervirens*, and *Lisianthus sempervirens*, yet Catesby says that it sheds its leaves in winter in its native place, America, where it is popularly called "Carolina Jessamine." Parkinson cultivated it in 1649, and says that it was given to him by Tradescent under the name of *Gelsemium*, which is derived from *Gelsemium*, the Italian name for the Jasmine. We shall be obliged by any of our readers stating their successful mode of culture, and whether they have succeeded in blooming it out of doors.

TRAINING VINES HORIZONTALLY. (*Inquirer*).—Your Vines receiving little or no artificial heat will not require to be brought to a horizontal position, nor depressed at the ends; but if they have a cane of last year more than six eyes in length, that part should have its end brought lower than the bottom of the gutter, otherwise the upper part or end will break some few eyes strongly, and those lower down on the cane will not break at all, or very weakly. If the Vines are furnished with spurs from bottom to top of the rod, and air be given at the back of the house, they will break well throughout the length of the rod, but more strongly at top, as they almost always do.

SEASONAL CROPS OF PEAS. (*Constant Subscriber*).—Having sown Dillston's Prolific and Kinglander, you may sow Dielsou's Favourite by the time this appears in print, and in ten days afterwards sow Prizetaker, in another ten days Champion of England, and seasonal crops of it every ten days up to the end of April, at which time sow Veitch's Perfection, another crop of the same ten days later, and after a like interval sow General Wyndham, once in May, and a last crop in the first week of June.

ROSE-BUDS. (*S. N.*).—We never heard of any florist or nurseryman who would sell buds for budding.

VINEY AND PEACHERY CONTINUED. (*H. Vaughan*). In your house, 50 feet long, 11 feet wide, 12 feet in height at back, and 6 feet in height in front, and to be appropriated to Vines and Peaches, Peaches against the back wall, and Vines up the roof, we do not consider that you want anything in the shape of a pit at all in the house. We would proceed as follows, according as you wish the roots of Vines and Peaches to be inside the house, or the roots of the Vines partly outside, and according to the materials at command, bearing in mind that though we advocate fresh loam, yet good garden soil would do very well, especially if well mixed with fresh soil and enriched. First, To have all the roots inside. It would be well to concrete the bottom of the soil from 30 to 36 inches below the intended surface, and to have a drain in front lower than the concrete, the concrete sloping from back to front to the drain. Then, if you can get it, fill the place with fresh loam from the topsoil of a pasture, after ploughing from 8 to 12 inches of rubble over the concrete. In doing this place the turf over the concrete, and let the rest consist of the soil from the pasture taken over under the grass for 2 or 3 inches in thickness. Let this be broken with the spade, but not finely, and for such a space add one ton of broken boiled bones, three cartloads of rotten sweet hoed manure, and three or four loads of lime rubbish. If you cannot get pasture soil you may use good fresh loamy soil in the sides of roads in your neighbourhood. If there is no danger of stagnant water, no chance of the roots going down into bad cold subsoil, you may dispense with draining and concreting; but it is very possible you may wish you had done so afterwards. If the soil of the garden is good, you may use that with half, or less, new soil mixed with it, and the same amount of bones, and even more lime rubbish, and loss of manure. Strength can always be given by surface-dressings, and that is the best way to use bone dust. In this case we would plant the Peaches at back, and the Vines in a row about 3 or 4 feet from the front wall, and if you liked, you could arch the stems over towards the front, so that the bearing rods should extend from front to back of the glass. The position for planting the Vines will be the best for enabling them and the Peaches to root freely inside the house, and will also enable you to have a walk all round the house, with a border or bed in the middle, which you can appropriate to any purpose that will not cause the Peaches on the back wall to be shaded. By such a plan the roots will be confined entirely inside the house, and in the openings between the Vines you could grow low-fruited plants, as Figs, Cherries, &c., in pots on the bed or floor. By surface-dressings you could keep Peaches and Vines long fruitful by such a plan, and you would have them completely under control, as respects moisture and dryness. To do justice to the Peaches, the Vines should be planted about 6 feet apart, and pruned on the spur system, say seven in the length of the house, and for an unheated house we would have four Black Hamburgs, two Royal Muscadine, and one Buckland Sweetwater. By the second mode we would have the front wall built on arches, or have pillars to support the sill, extend the border on the same slope as inside, from 6 to 12 feet beyond the wall, and in that case we would plant the Vines inside, from 18 to 24 inches from the front wall. This would give more room to the roots of the Peaches, and offer less risk of the roots of Peach trees and Vines interfering with each other, but would require more labour and material. In such a case the great thing to secure is, to have the inside ground higher than the outside. In either case you could use the centre of the house for temporary purposes, and might have fruit trees of any sort in pots before the Peach trees and Vines were established. A good Peach-house alone could be made of such a house, by planting the back wall as you propose, and then planting similar trees within 2 feet of the front wall, and training them to a circular trellis 4 feet in height at back, and 3 feet from back wall. We have seen such a house with Vines also up the roof, but it is not very thin they were sure to injure the Peach trees with their shade. As to terra cotta or other material as boxes for windows, there used to be plenty of kinds in the New Road, London, such as at Austin & Seeley's, and there are so many inquiries that it would be worth while for makers to advertise, giving prices and sizes. Mr. Franklin, at the Steyning Depot, keeps a good assortment of elegant vases, and we have no doubt there are plenty of makers. A rich brown tint generally looks best for houses that are painted a stone colour; but where there is a difficulty in obtaining elegant figured terra cotta boxes, much may be done by making neat wooden boxes, which may be painted of any colour and sanded to resemble stone, and may be tessellated, striped, or engraved, by tacking suitable pieces on, so that when sanded they would resemble different kinds of stone, and have the advantage of being much easier to move. Terra cotta boxes, however, may be had in great variety in London. We do not know how you are in your neighbourhood. The last time we were at Messrs. Veitch's nursery, there were plenty to choose from.

PRUNING MORELLO CHERRIES. (*An Early Subscriber*).—In general it is better not to shorten in the shoots of Morello Cherry trees at all, if they are in good bearing condition, but to thin them out pretty well. Where, however, it is necessary to shorten such shoots, the wood-bud may be distinguished from the bloom-bud by its being smaller and more pointed. It is better, however, to leave the pruning of such trees till late in the winter, when the advanced state of the buds will tell their character much better, and the tree does not suffer thereby. Of course, do not let the buds be too far advanced to fall off in the operation, which they easily do.

WELLINGTONIA GRANATA. (*H. Porter, M.D.*).—Thank you for the male and female catkins of *Wellingtonia gigantea*. The one you sent is not impregnated as you suppose, but an impregnated one. Impregnation takes place at the stage in which the catkins at present are, and although insects and the wind will doubtless aid in the process, there can be no harm in shaking the branches against each other as you suggest.

VINE LEAVES SPOTTED. (*J. C.*).—The leaf sent exhibits the spotted appearance resulting from the admission of cold air in front whilst the leaves are wet, and the sun shining powerfully upon them. We have also known the same result arise from pouring water upon the pipes whilst they were hot, and the sun shining on the condensed steam.

MUSHROOM-BED FAILING. (*C. J.*).—As one bed of Mushrooms bears well, and the other shows well but the Mushrooms rot off when the size of small marbles, we suspect that the bed is either too dry or too wet, not at the surface, but some inches below the surface. You will judge best by making some holes with your fingers and trying. If the manure is dry, make little holes over the bed with a pointed stick and water several times, so as to wet the manure a little without soaking the bed. If the bed is too wet, sweep off the most of the Mushrooms and cover with 3 inches of rough hay; that may tend to heat and dry the bed.

KALMIA LATIFOLIA CULTURE IN A POT (*A Subscriber from the Beginning*).—Your plan will be to give it a somewhat large pot, drain it well, and use a compost of turfy peat chopped with a spade but not sifted. If you will do this, and plentifully supply the plant with water when making new growths, and keep it at all times moist, with the pot plunged to the rim in coal ashes in a warm open situation, you will find it a free-blooming shrub. This is all the pains we take with ours for forcing. We take up good strong bushy plants, not them in pots sufficiently large to hold them comfortably, draining the pots efficiently, and using a compost of turfy brown peat or bog soil, plunge the pots to the rim in coal ashes in a sheltered open situation, and keep the plants well supplied with water throughout the summer, and at all times moist, and we find them set plenty of bloom, which we bring out by placing them in a house with a temperature of 50° by night and not exceeding 55°. They are placed in a house having a temperature of from 40° to 45° for three weeks, and are then introduced into the above temperature. They are taken outside after blooming, and placed in the same situation as before, where they remain over winter. Being potted in spring they make a good growth, and are eligible for forcing again in the following winter. They require a rather large pot for their size, and plenty of water in summer.

SOOT WATER FOR EVAPORATING-PANS (*C. P.*).—Take a peck of soot-plant in the bottom of a butt or barrel, work it into a stiffish paste with an old scrub-broom, with two or three quarts of water so as to wet the powdery dry soot, then add from forty to sixty quarts, stirring all well together. If you wish the water to be clear, add a pound of fresh lime, and in a day or two you may fill the pans with strong clear soot liquid. Take flowers of sulphur, say one pound, mix it up in a paste with a small quantity of water, then add a dozen quarts, or more if you like, and put by itself in the evaporating-pans, or mixed with the soot or other water. In this case the sulphur will fall to the bottom, and may want brushing up at times. When the water in the pans gets hot, wet sulphur effluvia will be given off. This is a safer plan than putting sulphur point at once on pipes or flues.

HEATING A MUSHROOM-HOUSE (*Fingus*).—Two three-inch pipes will be ample for such a small Mushroom-house (10 feet by 6 feet), if the walls are secure. The house seems low (5½ feet at back), to do work in comfortably. The pipes should not go below the beds, there would be danger of over-heat as well as over-dryness. It is of little consequence whether the shell or platform-bed have the bottom open or close; when open, Mushrooms frequently come through; when solid, as slate, woodlice are less troublesome. Open-spar slating is the worst roof for such a Mushroom-house, packing with hay or straw will be advisable. A thatched roof would be better. Have a stop-cock as proposed. If the bed out of doors has been wet, and has been made four months, most likely the spawn has perished. Try a bit of the bed and see. If the spawn is sound, it will no doubt produce a jet.

REMOVING LEAVES FROM CUTTINGS (*H. D. T.*).—The propriety of allowing leaves to remain on cuttings, or removing a good portion of them, depends entirely on the treatment you are able to give them. Remove not a leaf, say some—and right enough too, if you can so arrange that by a close atmosphere, shading from sun, &c., you can keep these leaves from flagging, in other words, force them to absorb rather more than they perspire; then the more leaves on the cutting the sooner will roots be formed, and the plant established. Remove most of the leaves, say others—and if enough are left to keep on growth, the cutting will be longer in striking, but it will require less trouble in preventing flagging from extra evaporation. Generally the medium mode is resorted to, a few leaves are removed from the base of the cutting, and some of the other larger leaves are shortened, the smaller allowed to remain to keep on the growth. In the case of Calceolarias, to which you refer, we generally remove the two leaves at the bottom, or the joint at which we cut across, and leave the others mostly as they are; but then making the cuttings in the end of October, they suffer little from the evaporation of their juices. Were we making cuttings of similar plants in April, we would reduce the foliage or shade them.

FORMING A VINERY OUT OF A PIT (*An Eight-years Subscriber*).—If you cement the bottom of the pit as you propose, place 6 or 8 inches of open rubble over it, and then a layer or two of fresh turf, grass side downwards. You may use from 9 inches to a foot of such fresh turf with a portion of broken bones; you may use the rest of the turf, mixed with other soil, for another layer, and a portion of the bones and lime rubbish, but have nothing to do with the stuff dug out of the foundations for the greenhouse. Surely you might get a couple of loads or two of good loam from the sides of a highway to mix with lime rubbish, &c.; if not, take some of the best aired sweetened soil from the kitchen garden. Any Vines may be grown in such a pit, heated as it is by flues. We have given lists to-day and last week to suit cold houses. Four Vines will be enough, or three if you confine them to the rafters. If entirely for Vines you might try five—say one Sweetwater for earliness, one Muscat of Alexandria, two Black Hamburgs, and one Lady Downe's for late cutting. Use spur pruning.

RADISHES IN POTATO FRAME (*Autum*).—You did quite right to keep on the lights, the Radishes will not become drawn, air being given in mild weather, especially as the bed is cold. After the seed leaves appear it is necessary to give air plentifully, but when there are rough leaves it is not possible to keep the lights otherwise than closed in frosty weather, air being given in mild periods. They will not draw up so much as to sustain injury, only they do not stand too close or rank a beat.

RHUBARB FORCING (*Idem*).—The roots should be laid on a few inches of soil, and pretty closely together, and soil should then be packed or placed between them so as to fill up the intervals; soil should likewise be placed against the sides so as to cover the roots. They will assuredly root into the soil if it is kept moderately moist. The rotting of the stalks is due to the roots being so closely packed, certainly not from the absence of soil. Good strong roots only are eligible for forcing, those planted three or four years answer well.

BROWN VARNISH FOR WOODWORK (*H. J.*).—Sorted gum anime 8 lbs.; clarified oil 3 gallons; litharge and powdered dried sugar of lead, of each ½ lb.; boil till it strings well, then cool a little, thin with oil of turpentine 5½ gallons, and strain.

PINE-APPLE PLANTS (*M. W.*).—We do not know where you can obtain any. You had better insert a short advertisement stating precisely what you require.

HYACINTH (*N. C. Nenagh*).—The spike you mention is fine; but at the Royal Horticultural Society's Show last week there were many still finer.

CAMELLIA FLOWERS POOR (*A Lady Gardener*).—We fear that it is now too late to thin the blooms of your Camellia plants, which you say are five or six on the tip of each shoot on trees only 2 feet high. The bloom-buds ought to have been removed in September or before, leaving only one at the point of each shoot. It is, however, good practice to thin such buds by degrees, taking off a few at a time, and, when they are about the size of a Pea. You may remove some of the smaller ones now, but it is too late to expect large blooms this year; after blooming, if the plants want potting, let that be done, and keep them rather close and warm until June, when they may be gradually inured to the open air, and buds will then be forming. Thin them in August, or at latest in September, and you will have more success another year.

FLOWER BORDER PLANTING (*A Regular Subscriber*).—If your border abuts at once on gravel, with a box edging, or tile or stone bordering intervening, then we would like the "master's" choice as well as your own; but if there is a grass verge between the border and walk, then we prefer your proposed mode of planting—namely, beginning at the front with *Bijon Geranium*; second row, *Calceolaria Aurea floribunda*; third, *Perilla nankinensis*; fourth, *Fanch Geranium*.

VENTILATING TWO ADJOINING GREENHOUSES (*D. D.*).—By opening the door of your first house, or having larger openings above the door, and in the opposite end, you would have a lower temperature and a rather close moist atmosphere to suit your Ferns, and there we would chiefly place them. In your new house, 10 feet by 6, and with glass merely on the roof, if you did not open the door we would either have three openings, say 12 inches by 18 each, in the front or back wall, or two large openings a yard square in each end. Then on the shelves you propose, you could grow *Fuchsias*, *Geraniums*, &c.; and if you wish, Ferns, &c., as you intimate, then we would keep them chiefly on the shelf inside of the front wall, as that would keep them from a fierce sun.

SIX ROSES FOR NORTH WALL (*J. W. B.*).—For quick growth and flowering early in the season, we would have *Felicite perpetue*, one of the best-foliated Roses known; then you might either have *Jane Hardy*, *Yellow Noisette*, and *Fullenberg*, a crimson of the same class; *Bouquet de Flore*, one of the best Bourbons; and *Aimee Vibert*, a good old Rose of the Noisette section. We fear the *Banksian* Roses would not succeed against a north wall, but you might try *Gloire de Rosmeur*, a showy Rose less rampant than some others. We would not recommend you to try *Teas*, as they are too tender, and so, too, is the *Macartney Rose*.

PEACH TREES SHIELDING THEIR FRUIT (*Norfolk*).—We think that your trees cast their fruit in the process of stoning, and this is mostly due to over-cropping, and in some cases to the roots being deep and wet. In the former case thinning the fruit so as to leave three to every two square feet of wall covered will prevent it to a great extent; but if it proceeds from the roots being deep and wet, thorough draining is the best remedy, the trees being removed next autumn and the roots brought nearer the surface. If the fruit drops when the second swelling takes place, then it may result from want of moisture. A good watering a fortnight previous to the swelling for ripening, would cause the fruit to swell well, but it is of no use giving surface waterings, one good soaking is worth ten of them. The fruit drops very often prematurely from the leaves being destroyed by red spider. Frequent syringings will prevent this evil.

GLADIOLUS SEED SOWING (*Idem*).—The seed should be sown in pans of good, rather light, turfy loam two thirds, and sandy peat one third. Place the pans in a steady heat of from 50° to 55°. The seeds if sown in October will produce by this time nice little plants from 1 to 3 inches high, and these, rested and hardened for a month, may be planted out in a warm border. In autumn they will have plump little bulbs calculated to bloom in the following year.

PLANTS FOR WALLS OR PIERS IN CONSERVATORY (*Sussex*).—*Cissis ant' arctica*, *Cobea scandens variegata*, *Clematis indivisa lobata*, *Dolichos lignosus*, *Hibbertia grossularifolia*, *H. volubilis*, *Kennedia inophylla floribunda*, *Habrothamnus elegans*, *Sollya linearis*, *Mimosa prostrata*, *Tropaeolum speciosum*, *Solanum jasminiflorum variegatum*, *Jasminum heterophyllum*, *Bignonia jasminoides splendida*, and *Abutilon striatum*.

ROSES FOR CONSERVATORY (*Idem*).—*Noisette*: *Celine Forestier*, *Miss Gray*, *Jane Hardy*, *Aimee Vibert*, *Ophire*. *Tracensee*: *Adam*, *Gloire de Dijon*, *Devoniensis*, *Alba rosea*, *Josephine Malton*, *La Boule d'Or*, *Madame Falcot*, *Marchal Neil*, *Niphetos*, *Triomphe de Luxembourg*, and *Smith's Yellow*.

ACACIAS FOR POT CULTURE (*Idem*).—*Acacia Drummondii*, *A. juniperina*, *oleifolia elegans*, *graudis*, *hybrida*, *longiflora magnifica*, and *crucicarpa*. None is more beautiful than *A. armata*, which you have.

FLOWER-BEDS (*J. P. M.*).—We think either plan would look very well, but viewed from the window, we ourselves would prefer more variety—thus, 1, Centre Golden Chain, band of blue *Lobelia*, edging of *Cerastium*; 2, 2, Scarlet *Geranium* and *Manglesii* for edging; 3, 3, yellow *Calceolaria* and *Purple King*; 4, 4, Scarlet *Geranium*, edged with *Flower of the Day*, thick, and the flowers removed; 5, 5, the same as 1, 1. In order that all the edgings may be light, you might skirt round 3, 3, with a narrow belt of variegated *Arabis* or variegated *Alyssum*. Notices of *Shrubland Park* by Mr. Beaton will be found in Number 261, 262, 417, 418, 421, Old Series; and by Mr. Fish in Numbers 472, 473, 476, and 477, all of which may be had from our office.

RASPBERRY CANES HAVING LATERAL SHOOTS (*A Lady Gardener*).—It is seldom that much good is done with them, and they may as well be cut off or shortened; if, however, these shoots have produced fruit last year, we fear your chance of a crop this season is not good. Some kinds, as the *Fasfold*, are with us very liable to bear on the current year's shoots, and as a consequence these shoots are useless for the next year, and ought to be cut out at pruning-time; but, as you say yours are vigorous, it is likely they have not borne fruit, and may do well. We should be disposed to leave some of these shoots on the canes newly planted, for their foliage will help the plant to make fresh canes, and much fruit can not be expected.

NAMES OF FRUITS (*Op. D.*).—Old Colmar Pear.

NAMES OF PLANTS (*Lex*).—Your correspondent's handwriting must be difficult to decipher. The plants intended by him are *Bursaria spinosa*, a native of New South Wales. *Melanthea decussata* is also from New South Wales. *Sida mollis*, a native of Peru, requires stove culture. *Isoegon anomomifolius*, a native of New South Wales. *Arthropodium paniculatum*, a bulbous-rooted plant, also from New South Wales. The

New South Wales plants require greenhouse culture. There are coloured drawings of them all in the "Botanical Magazine." (*J. B. P.*)—1, *Nephrodium exaltatum*; 2, *Pteris cretica* (?); 3, *Lastrea glabella*; 4, *Lastrea atrovirens*; 5, *Woodwardia radicans* (?); 6, *Selaginella casia*. (*H. F. U.*) 1, *Onychium japonicum*; 2, *Pteris linearis*; 3, *Adiantum formosum*; 4, *Adiantum pubescens*; 5, *Aspidium molle*; 6, *Aspidium flaccidum*; 7, *Platyium rotundifolium*; 8, *Selaginella dealbata* (?). (*A. Constant*

Reader).—Most of the scraps sent are not sufficient for determination. 1, *Asplenium minimum*; 2, *Asplenium flabelliforme*; 4, *Polypodium vulgare*; 5, *Lomaria calypina* (?); 6, *Adiantum cuneatum*; 7, *Aspidium macrophyllum*. (*An Engineer*).—*Eselynanthus zeylanicus*. (*A Subscriber, Billinadoc*).—1, insufficient for identification; 2, probably a scrap of *Pteris cretica*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 17th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun. . . 11	30.299	30.154	45	36	41	40½	S.W.	.00	Overcast; cloudy; fine at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME BANTAMS.

I HAVE carefully read the various letters which have appeared in the Journal on this subject, and although late in the field should like to have my say also, which shall not occupy much of your space.

I was a breeder of Black Red Game Bantams thirty years ago, long before poultry shows were thought of, having a stock derived from birds of the late Duchess of Rutland's, of happy memory; and although these were not equal to the best birds exhibited at our shows, they possessed, however, all the characteristics of the noble Game fowl. I am still a breeder of the despised "pigmies," and do most earnestly aver that so far from being easy to breed, they are the most difficult of all the varieties which I have tried (and their name is legion). A letter from a friend, who has bred these birds for fifteen years, now lies before me, in which he states that his opinion fully coincides with my own, and that the new axiom which Mr. Crosland has put forth—viz., "To breed good birds you must breed in-and-in for generation after generation, until *avi avorum numerantur*, without infusing fresh blood, is a most absurd doctrine for any experienced breeder to promulgate. I have letters from numerous other breeders to the same effect, that from pursuing such a course the birds "throw back," "degenerate in every way," "become weak in constitution," and "in due course worthless."

My stock, derived from two of the most renowned breeders and successful exhibitors of these birds, at the beginning of last season consisted of six hens and one cock. The latter had been exhibited many times, and never without winning, at all the principal shows. The former were extremely good, and free from silver earlobes. From these I raised upwards of one hundred chickens, about half of each sex. The pullets, with two exceptions, had silver earlobes, and of the cockerels there were not more than three which would, by really skilful judges, be termed "first-class." Indeed, the largest exhibitor of Game and other breeds has given it as his opinion, that "only three first-class Game cockerels are 'out' this season," and this, too, from all the myriads, I had almost said, of the "miniatures" produced by the "pigmy" loving and enthusiastic maniacs who sent ninety and nine pens to Bingley Hall, to the disgust of our old friend the "WILTSHIRE BECTOR."—*ALIQUIS.*

P.S.—I have just seen Mr. Newsome's letter, and am surprised to find that he has not won a single prize for Game Bantams at any of our three largest shows during the season which has just closed, with the exception of the third prize at Rochdale, for a pen of Black Game Bantams. He did not exhibit at Birmingham. At Manchester he showed four pens and did not obtain a single notice! and at Rochdale he abstained from exhibiting in the Black Red Game Bantam class. Do not these facts speak volumes! Mr. Noble's name does not appear in the catalogues of any of the above-named shows. After reading carefully Mr. Newsome's letter, I am still more

confirmed in my own opinion, that it is by no means an easy matter to breed these "easy-to-breed first-class Game Bantams."

HAVING perused the letter from "CHESHIRE PILE," I shall be glad if you will allow me to make a few remarks on that portion of it referring to my financial account of Game Bantam breeding. In the first place, I have sold £180 worth, and all my own strain, which I have had for years. I have also bought largely for applicants, or, I should say, I have been commissioned to buy birds such as I could recommend, though at a lower price than my own were sold at. I have bought upwards of £50 worth in this manner, and no doubt from as good yards as my own. I know breeders that I can depend upon, from whom I would take all they had at a guinea each, and when needful these are the yards from which I can be supplied; and if "CHESHIRE PILE" does not know where the birds are to be found, and will hand me his address, I will supply him with a pen up to the "Standard of Excellence," though the price might be rather too high according to his ideas. There are, however, parties who give large prices, who, perhaps, have as good fowls as myself, and who do not scruple to give £10 or £15 for a single cock. I have sold eight Game Bantams for £50 15s., and all to first-class men who do not mind giving a first-class price when they can depend on good blood, to make an equal cross with their own.

Can "CHESHIRE PILE" account for the fact that certain breeders of Game Bantams invariably succeed in prize-taking? Can it be that only a portion out of a great many fanciers are well acquainted with breeding, and who are also able to judge a good bird on seeing one? If so, judging from his remarks, I fear he forms one of the majority of unsuccessful breeders.

I should like to give "CHESHIRE PILE" a few particulars of my private view of Bingley Hall in 1865. I first went to look over the Game and Game Bantam classes, and on finding my success in Game was satisfactory, I passed on to the Game Bantams, catalogue in hand, and again had the satisfaction of finding that in these classes I had also been successful; and on looking through the single Game Bantam cock classes, I noticed three first-class birds marked as follows:—£2 5s., £3 3s., and £5 5s. I was rather astonished on fully inspecting them, that according to my own judgment the best bird was marked at the lowest figure; and as the whole three belonged to one owner, I certainly thought he had made a mistake in penning his birds. However, I took care to claim the lowest-priced bird at the proper time, and in the course of the day I had £5 offered for him from several first-class fanciers. All their propositions I, however, declined; and although I had a first-class bird at home, I showed this bird in the single cock class at Manchester, and took the second prize, and there I sold him for £10. I may also remark that the same bird has taken a first prize at Rochdale. Now, I am of the firm opinion that the above were all the property of "P." who, I must acknowledge, made a decided hit in his communication inserted in your Journal of the 13th ult. He appears to have good judgment in breeding quantity; as to his judgment of quality I will leave it for your readers to decide upon, after perusing the foregoing statements respecting his lowest-priced cock at Bingley Hall.

After a great many years experience in Game Bantam breeding, I must endorse the "WILTSHIRE RECTOR'S" statement that they are easy to breed good; and as "GALLUS," "P.," "W. F. E.," and "CHESHIRE PILE," appear to be of the opposite opinion, I would advise them without delay to purchase the "Standard of Excellence" and digest the contents thereof, and it is possible that their present opinions may be altered.—JOHN CROSLAND, JUN.

THE FINALE.

The time having now arrived when, in the judgment of the Editors, this passage of pens should cease (verily a large amount of type has been used on a very small subject; it has been the reverse of the mountain bringing forth the mouse; and the little birds, could they know it, would be more fussy than ever), it becomes me to say a few concluding words, as a remark of mine originated this rush to pens, to my own great surprise and infinite amusement.

I stated that Game Bantams were "easy to breed." The discussion has been conducted by two parties: one which knows how to breed them good, the other which does not yet know how. It is simply a case of knowing how to do it, and of not knowing how to do it. It has been clearly proved that Game Bantams are easy to breed good by those who thoroughly understand the breeding of them. My opponents have been "GALLUS," "P.," and "A CHESHIRE PILE," also "W. F. E.," who wrote civilly, though differing from me in opinion. On my side was the greatest breeder of these fowls, Mr. J. Crosland, who stated that "he quite agreed with me," and that "he breeds every year a large number of first-class birds." It was not wise for any one to speak in opposition to Mr. Crosland, for he breeds the best birds in the kingdom, for the simple reason that he best knows how to do it. Then came my friend "WEST YORKSHIREMAN," who showed that he had gradually learnt how to do it; his letter is very valuable; then, lastly, Mr. Newsome's long and able communication (I hope some time or other to have the pleasure of meeting him), and he, too, has learnt how to do it. I am extremely obliged to those who have written on my side and proved the truth of what I stated. I have not the least personal knowledge of any of them, and not only do I thank them, but, as a gentleman, I feel particularly glad that they all wrote in such a gentlemanly manner. I think the results of this discussion will be, that possibly fewer Game Bantams will be shown, but most probably they will be better birds. Also the needless multiplication of crosses will cease, and good strains will be kept to, while bad ones will be destroyed. It is wonderful how true the little creatures come if they be of a thoroughly good strain. In conclusion, I would remark that I shall in the future, as in the past, state just what I think, quite independently of any class interest, but keep the interest of poultry on the whole always before me. Thanking my friends, I also hope my opponents will cease to stumble on the road to success, and will learn how to breed their pets to their own content and the approval of the judges.—WILTSHIRE RECTOR.

[We think this controversy may now cease, for a quire of letters would not convince any one of the combatants that his opponents are right; and the same amount of letters will elicit no other information for our readers, than that some poultry fanciers find it difficult to breed very superior Game Bantams, whilst others have experienced no such difficulty. We know the exhibited birds of all the controversialists, and we can testify that we never saw among them one inferior specimen.—Eds.]

VULTURE HOCKS—WHITE RUMPS—
ERRONEOUS NAMES.

I PERCEIVE there has been some discussion in the Journal as to the vulture hocks in Shanghaes or Cochins, and I quite agree with those of your correspondents who advocate vulture hocks in Cochins. In my opinion they are quite in keeping with the general form of the birds, and really belong to them as much as feathered legs, of which, indeed, I consider them a part; and, consequently, I admire them.

As to Blue Dragons having white rumps, I consider it quite natural and as consistent for blue Pigeons to have white rumps as for them to have black bars across the wings. It is part and parcel of the true blue colour. Some fanciers, I am aware, object to any colour like that of the wild bird or natural colour; such, of course, will discard blue altogether on that account,

and will prefer any variation from the true blue, or original colour, which, I think, is rather inconsistent; if blue, let us have the true blue.

I am glad to notice that one of your correspondents objects to the incorrect names applied to fowls. I have written much on the subject, but generally met with more opposition than encouragement. He is quite right in what he says, it is a folly to call poultry by false names. The fowl that came from Ham-burgh was a crested bird, still much bred on the continent, particularly in Belgium, and now known there as "Brabanter." Polands and Polish should be called Crested Fowls. Cochins and Brahmas are properly Shanghaes, or Chinese. The Bebe, or Black East Indian Ducks, have nothing to do with Buenos Ayres or Labrador; and the Musk Ducks come from Brazil, not from Muscovy.—B. P. BRENT.

RAILWAY CHARGES.

SINCE the first list of those willing to sign the requisition to the railway authorities, I have received communications from others, as the subjoined list will show. There are many who have not taken any notice of my circular, but I have only received one direct refusal, a name we shall miss here, though very rarely missing in the prize list. As the refusal gave no reasons, I could not, as in one or two instances I have done, show the necessity of helping, but I regret the omission, and can only hope that before the requisitions are presented, exhibitors may yet be persuaded to sign.

From the many communications I have received, I am disposed to think that a uniform rate, considerably lower than for other parcels, both ways, would meet the general wishes of exhibitors more than returning specimens FREE. I should be very glad to receive the names of any exhibitors who would form part of the deputation.

The following are the additional names that I have received:

| J. Fletcher, 10s. 6d. | |

—JOSEPH HINTON (Y. B. A. Z.), *Hinton, near Bath.*

SOUTHERN POULTRY SHOWS.

I AM truly glad that my words on this subject have called forth "BRAHMA POOTRA'S" letter. I have also received a note announcing that there will be a poultry show at New Shoreham, Sussex, next autumn, to be called "The South of England Poultry Show." This is well. "May I be there to see?" Another letter has reached me, naming Bristol as a most suitable place for a show. Some widely-known first-class poultry fanciers reside in and near that city, and Pigeon-lovers, especially of the flying varieties, abound; some pens of these latter, stating the distances they have flown, would be an acquisition.

I certainly think there ought to be several efforts made to establish shows in the south. Some of our greatest and most successful fanciers, whose names will at once occur to the minds of all readers of this Journal, live in the south of England, or, at any rate, not in the north. An outlay of many pounds is expended by them in sending to northern shows; surely, then, it would only be fair to them that there should be shows nearer home, and doubtless northern fanciers would send their birds south. I would say, There should be no show unless there is a fairly-good population, and a railway station near. Why not engraft a show upon a horticultural exhibition, or a ploughing match, or a meeting of a county friendly society or club, or a fair. Wherever numbers are drawn together for any purpose, there might be a poultry show, and, I will venture to predict, the tent will be full.

"EGOMET" speaks an encouraging word when he says, "Our Show (not in the north), was a surprise, for we had not only a balance sheet, but actually a balance in hand—a nice little nest-egg for this year." By the way, I like "EGOMET," he has

a pleasant sense of humour, and writes like a gentleman. In all controversies it would be well for all to remember, as apparently he does, George Herbert's words—

"Fierceness makes
Error a fault, and Truth discourtesy."

In passing, I must assure "EGOMET" my not continuing my "Notes on Pigeons" has not willingly been delayed by me. My good friends at 171, Fleet Street, wished me to go to Birmingham, and writing my "First Impressions of Bingley Hall" took up my time. Then they wished me to write for the Christmas Number, and writing three papers for it took up my time. Then came "GALLUS" and "P." with their hackles up and spurs on, and dispatching them took up a little of my time. Then came my visit to Linton Park, and describing it took up my time. However, I hope to continue the Pigeon subject shortly, and have been smelling the old books with gusto this very day. Mine is, from many causes, no life of leisure, so let "EGOMET" rest assured I have been a "Rambler" only per force, and am never an "Idler."—WILTSHIRE RECTOR.

P.S.—A letter of inquiry about fowls has just come to hand from a fair lady, and another from "AN AMATEUR." Like Banquo's ghosts they multiply, I think I must send some on to "EGOMET," to take a gentle revenge.—W. R.

VULTURE HOCKS, &c.

I HAVE been waiting, "like Patience on a monument," for an answer from the "able judge" who considers vulture hocks a recent introduction—waiting, in fact, for a pointing in words of what a Cochin or Brahma leg (for in this they are identical), ought to be. I asked for it, and after so sweeping a denunciation of the vulture hock and all approach to it, I feel that we breeders, who are not converts to the "recent" idea, have some right to an answer to my query.

I believe I am the oldest exhibitor of Brahmas, I will not be certain on this point, but I believe I am correct, the first prize I ever gained for the first pen I ever exhibited having been taken at the old Gloucester Agricultural Society—the poultry portion, alas! now defunct—in November, 1854, nearly twelve years ago; and as I look up the date in the old "Poultry Chronicle," I am filled with regret; for the same Number of that periodical contained notices of Brighton, Taunton, Salisbury, and Gloucester. Of these four southern shows, Brighton only remains to us! Well may "WILTSHIRE RECTOR" have a grievance; but what of us exhibitors who have to send so much farther in these days of light (?) expenses for railway carriage!

My pen is on the wing, whereas I was intending to speak of the leg; so let me return to it. In all seriousness I again ask for the "able judge's" definition of a Brahma leg. Before he give it, let me refer him to No. 3 of the new edition of the "Poultry Book." There he will see drawings of Light and Dark Brahmas of 1852 and 1853, copies from the *Illustrated London News* of that time. The hock feathers project quite the sixteenth of an inch, equivalent to an inch in the actual bird, but in the Dark birds it is considerably more. Can he then say that the projecting hock is a recent introduction? I hazard the opinion that the feathering down the outer part of the middle toe is more recent, and that this feathering, which is a great improvement, and, I believe, is now sought after, has come from the stiff-feathered-hocked birds; if I am correct, we owe this improvement to the vulture hock. I fear we shall lose that and the projecting feathering below the hock if we are forced to breed naked-hocked birds to suit the fancies of judges. I believe this outcry against a moderate amount of hock-feathers in the Cochin and Brahma is certain to injure the breeds. I have too sincere an admiration for my favourite breed to see them docked of any beauties and remain silent. For myself, whether successful or not, I shall endeavour to retain a moderate amount of hock-feathers, believing that this is the natural condition of the breed, and convinced that in any case it is a very great addition to their beauty.—Y. B. A. Z.

MINGLING OF STRAINS—DRAGON PIGEONS.

THE "WILTSHIRE RECTOR," in the last Number of "our Journal," says, "As to crossing strains, I know three of the first breeders, if not the three very first breeders, respectively of Spanish, Dorkings, and Light Brahmas. I put this question to each of them, 'How often do you cross your strains?' The same answer came from each—'I dare not do it; when I have

done so I have obtained worse birds, or only my own back again.'" Will "WILTSHIRE RECTOR" kindly explain this? Do these eminent breeders breed in and in? or do they keep a number of yards and cross one with the other? or how do they prevent their breeds from deteriorating? As a Dorking and Brahma fancier I shall be very glad to have "WILTSHIRE RECTOR's" advice as to crossing.

As a Pigeon fancier I wish to say a few words on the Dragon controversy. I have lately purchased a splendid pair of Dragons (Blue), but they have white rumps. So had the first-prize Birmingham birds. Now, are white rumps really a defect or are they not? Mr. Percivall says they are, and ought to disqualify for prize-taking. On the other hand, "A DRAGON BREEDER" says the best birds as a rule have white rumps. Must we take Mr. Percivall's word for law? If Mr. Hewitt or Mr. Esquilant would give their opinion on the subject in your columns I think they would confer a great benefit on all Dragon fanciers, as their opinion would carry great weight. Mr. Brent ignores Dragons in his "Pigeon Book."

May I suggest that the Poultry Club would be doing good service to Pigeon fanciers by issuing a "Standard of Excellence in Pigeons" on the same plan as their valuable "Standard" in poultry?—AN AMATEUR.

["AN AMATEUR" is quite correct in his surmise that the three yards I alluded to are very extensive, and their owners, I believe, avoid as much as possible breeding from very near relations. When a fancier has arrived at the top of the tree it is manifestly impossible to get higher, and hard work to maintain his pre-eminence; but when one is on a lower branch it should be his object to rise each year higher and higher; and it is encouraging to beginners to know, as I know, that some of our very first fanciers exhibited for a long time without getting a single prize. More, I would say the gradual rising in prize-taking is owing partly, in breeds dependant upon weight for success, to the crossing a strain with a better—i. e., larger breed. So doing with judgment, putting few hens to a walk, hatching early, and feeding very liberally, will enable "AN AMATEUR" to improve his Dorkings and Brahmas. This gradual advance forms one of the excitements and chief pleasures of poultry-keeping. By the way, let "AN AMATEUR" be careful and choose his best birds each year for stock.]

In regard to the Dragon controversy my view is this. As white-rumped birds have recently taken first prize at Birmingham, that kind of feathering cannot amount to a disqualification. But supposing there were two pens of equal beauty in all points, but one pen white-rumped and the other not, I own I should incline to the opinion that the latter, as being the rarer, should have the prize. I have seen Mr. Percivall's birds, and think them extremely beautiful in colour.—WILTSHIRE RECTOR.]

DRAGON PIGEONS.

IN the Number for the 27th ult. I find an answer to my letter of the 6th of that month from Mr. Jones Percivall, of Peckham Rye, in which that gentleman says he is at a loss to understand how I should come to the conclusion that his first correspondence upon the subject came from Birmingham. I need only say, I found no difficulty in ascertaining the address of the supposed writer, when the foot of the letter furnished me with his name. Like their birds, the names of these gentlemen resemble each other so closely, that, to the fancy, I believe they are looked upon as synonymous.

Mr. Percivall next presumes that I thanked him for telling us what a good Dragon should be. If he refers to my letter again, he will find I gave him credit for trying to teach us what they should *not* be. I was in hopes, when he came calmly to reflect upon the mistake he had made, and the mischief he might do, he would have seen the folly of pronouncing, upon his own authority, white-rumped Dragons as worthless; as also those of other varieties, which would necessarily follow the same fate, and which I calculate would number about three-fourths of the Blue Pigeons in existence; and yet Mr. Percivall flatters himself he is thanked by me for committing such an error! He has made himself notorious amongst the fanciers of the midland counties for the peculiar opinions he entertains of Dragons—opinions at variance with the ideas of competent judges whose decisions I have sought and obtained.

Of the numbers of white-rumped Pigeons, which Mr. Percivall says may be bought for 1s. 6d. or 2s. each, I have no doubt, but not Dragons. If he had merely pronounced the blue-rumped birds as in his opinion better than the others, giving at

the same time some reasons for so doing, instead of declaring all others worthless, a notion so preposterous that it cannot be allowed to go unnoticed, his letter might have passed without comment, and he would not have thus laid himself open to censure. I have closely scrutinised many birds of each sort, and have given my reasons for upholding the white-rumped ones. I have found that the blue-rumped ones are generally ticked with small black spots upon the top portion of the wing-coverts, and as often have amongst those ticks one or two half-black feathers, which look as though a third bar were making its appearance. The latter sort resemble the Blue Fantail in colour, which is always of a more sombre, subdued tone, and lacks that brilliancy which a good Dragon should possess.

Mr. Percivall makes bad worse by pronouncing the same judgment upon Owls. He has avoided answering the question with regard to Powters. Runts and Antweeps, he tell us, rank so low in the estimation of the fancier, that it is a matter of indifference whether they be white-rumped or not. I beg to state that it is no more a matter of indifference in these classes than in Dragons or Owls, as they have each much to recommend them, and are worthy of more notice than Mr. Percivall is willing to allow.

Mr. Percivall says he is pleased that the Dragons he exhibited at Birmingham claimed my special admiration. This they certainly did; but it is not consistent in him to value that expression of opinion, when, in the former part of his letter, he says he cannot help thinking I am one of those who do not know what a good Dragon should be.

The last sentence of his letter needs but little comment from me, as he has admitted the error in matching the Archangels, and tells of his misfortune in losing one just before the Show, leaving him a stock of two odd birds to select his pair from, with no alternative but either to compromise his judgment or leave a vacant pen. He, therefore, chose the least loss of the two, and sent the birds for competition.

I hope my remarks may have the effect of convincing those interested that Mr. Percivall is wrong, and that he did not properly deliberate upon the wisdom of allowing to be set in type for public criticism views not rightly matured.—A DRAGON BREEDER.

COMPARATIVE LONGEVITY OF THE LIGURIAN AND BLACK BEE.

I HAVE been much interested by the description given by Mr. W. G. Malin, in page 212, of his experience of bee-keeping in the city of Philadelphia, and hope that the communications of that gentleman and Mr. Langstroth may prove the harbingers of a continuous free interchange of ideas through the pages of "our Journal," which cannot but tend to the advantage of apiarians on both sides of the Atlantic.

It is, therefore, in no captious spirit that I venture to point out an error into which Mr. Malin has fallen with regard to the comparative longevity of the Italian and the common bee, the fact being that there is no appreciable difference in this respect between the two races; and however solicitous I may be for the good name of the elegant and prolific variety which I have taken so active a part in introducing and disseminating in this country, I should be very sorry to permit it for one moment to be supposed that any superiority was claimed for the Ligurians to which they were not fairly entitled.

Judging from my own experience, I should say that Mr. Malin's mistake has arisen in this way:—After the first Italian queen had been introduced and favourably received, and had commenced egg-laying, she was probably deposed and murdered by her new subjects, who then raised a young queen from her brood, which, being impregnated by a common drone, bred a mixed race of black and Ligurian bees, the latter gradually diminishing in numbers as the progeny of the purer Italian queen died off. From their ultimately remaining in so small a minority as about one in thirty, I should be inclined to suspect the purity of the original Italian queen, whose hybridised daughter, being fertilised by a common drone, would in that case breed but few Ligurian workers.

I offer the above as the most probable explanation of the circumstances related by Mr. Malin, because I have known Italian queens, which were apparently at first well received, deposed and slain after they had commenced egg-laying, royal cells being at once constructed and young queens reared from the brood left behind by the murdered sovereign; but whether this be or be not the true explanation, I have ample experience

to justify me in declaring that there is in reality no distinguishable difference in the longevity of the Ligurian and the black bee.—A DEVONSHIRE BEE-KEEPER.

WOODBURY HIVES.

IN your Journal of May 31, 1864, we are told, "the top, bottom, and sides of each frame should be three-eighths of an inch from the crown and floor-boards, as well as from the sides of the box." But if the space above the bars be three-eighths of an inch, the bar itself three-eighths of an inch, inside measure of frame 7½ inches, the thickness of the bottom of the frame five-sixteenths of an inch, and the space between the frame and the floor-board be three-eighths of an inch—total, 8½ inches—I want to know how and where the remaining five-sixteenths are to be disposed of, "so that these dimensions may be rigidly adhered to."—EDWD. FAIRBROTHER.

[The reason of my frames being about a quarter of an inch shallower than nine-inch boxes would admit of is, that the latter are usually made out of nine-inch planks, which will in the first place seldom finish the full width, and generally shrink an eighth of an inch more under a summer's sun, whilst it matters little in practice whether the clear space under the frames be three-eighths or five-eighths of an inch. If you refer to my article you will find that it is the dimensions of the bars only which are required to be "rigidly adhered to," slight variations in other respects being of minor importance.—A DEVONSHIRE BEE-KEEPER.]

THE SEASONABLE TURKEY.

BIRD of two meats—the brown and white—

Which like the dual Niles unite

And in a single body run,

Of tints diverse, in substance one—

Hail to thy bosom broad and puffed!

Plump as a maiden's cotton-stuffed,

Hail to thy drumsticks, dainties fine,

That, served as "devils," seem divine,

(And mind us of had Frankish men

Browned to good purpose in Cayenne.)

Hail to thy side bones!—rich morceaux—

And thy ecclesiastic nose,

Which to the laws of order blind,

Nature has queerly placed behind.

Yet scoffers vow thy fitness see

In nose of bishop following thee,

And hint that ever on a priest

The organ points towards savory feast,

And as the shark astern, at sea

Trackst he doomed ship, still follows thee!

Metinks I see a dish borne in

O'ceanopied with shining tin:

From 'neath that dome a vapour rare

Curls through the hospitable air.

Presto! up goes the burnished lid,

And lo, the bird its concave hid!

I see thee, browned from crest to tail,

Bird of two meats, all hail! all hail!

Through thy round breast the keen steel glides,

Rich juices irrigate thy sides—

"Dressing," to give the slices zest,

Rolls from thy deep protuberant chest;

Then tunneling in search of "cates,"

The spoon thy "inards" excavates,

And forth, as from a darksome mine,

Bring treasures for which gods might pine.

Bird of the Banquet! what to thee

Are all the birds of melody?

Thy "merry-thought" far more I love

Than merriest music of the grove.

And in thy "gobble," deep and clear,

The gourmand's shibboleth I hear!

Of all earth's dainties there is none

Like thee, to thank the Lord upon.—(H. S.)

PARTRIDGES AND PHEASANTS.—A hen Partridge is sitting (March 9) at Lulworth, Dorsetshire, on a nest of eggs. She has been sitting more than a week. Silver Pheasants are showing for laying, and there is every indication of their doing so shortly.

HOW WE INTRODUCED ITALIAN BEES WITHOUT LOSING THEM.

1. We opened our hives to remove the black queens at times when there were few bees flying—say early in the morning. The consequence was, robbers did not "pitch in generally," and we were not troubled with them. If honey forage was abundant this precaution was unnecessary.

2. If robbers did attempt to trouble us at all, we removed the open hive into the house or somewhere beyond the reach of the pests, and took out the black queen at our leisure.

3. We always caged the Italian queen and placed the cage between two ranges of comb, which contained an abundance of honey, and left her caged there two or three days, then liberated her cautiously.

4. If we made an artificial swarm for the new queen, we did it while the bees were flying freely. We did not set the hive, containing a scant body guard and honey, where it would be a temptation to robbers; but set it on the stand of one of the most populous colonies in the apiary, removing the hive of the populous colony to a new stand considerably distant. The consequence was that the workers returning from the fields by hundreds, filled with honey, finding their home removed, and in its place a new hive, new combs, and new queen, would soon accept the whole. But, as a precaution, the queen was caged, and the entrance contracted that it might be easily guarded.—**W. C. CONDIT.**—(Prairie Farmer.)

OUR LETTER BOX.

MANDARIN DUCKS (K. D. T.).—The Ducks with raised feathers on their wings are Mandarin Ducks. We do not know whether they are eaten in China, but as they are generally worth £7 or £8 per pair, we think it will be some time before any one is qualified to give an opinion of their table qualities in this country.

JUDGES AND JUDGING IN SCOTLAND.—We have received several letters animadverting upon the communication entitled as above and signed "JUSTICIA." Every one of those letters denies the correctness of "JUSTICIA's" complaints. It is probable that they were written under the excitement of disappointment; but they have called attention to the subject, and, as the letters before us state that the judging at Paisley, Jedburgh, Kelso, and other places gave general satisfaction, there is no need for fearing that "JUSTICIA's" comments will be detrimental to the Scottish poultry shows.

POULTRY-KEEPING (Annie).—I will do my best to reply to my fair inquirer. First, I would advise her to send seven stamps to the office of "our Journal," and beg that a copy of "Poultry for the Many" may be sent to her; then let her master its contents. I would recommend her to obtain a sitting of Black Bantam eggs from Rev. G. W. St. John, of Woodstock; if he has none, I dare say Mr. Cambridge, of Bristol, would sell her some. "ANNIE" should look out for a broody hen, taking care that she has nothing of the Spanish or Hamburg breed in her. A common half-bred Bantam would be the best. The hen would sit in any quiet corner of an out-house, and may be shut in the whole twenty-one days. For particulars of attention to sitting hen, management of chickens, &c., see "Poultry for the Many." The reason I recommend a sitting of eggs is that there is a great charm in rearing chickens, and in watching their habits and dispositions. Then, too, fowls seen so thoroughly one's own, having had them from the first. Black Bantams lay very early. I have had them lay when twenty weeks old. They, if pullets, are good winter layers, and their eggs, especially in the spring, are larger than those of any Bantams I ever kept. But for the trouble "ANNIE" might have with her neighbours I should, as she has a paddock, have recommended Hamburgs, any of the four varieties, though I incline to the Silver for the country. At the end of the season let "ANNIE" save her best cockerel and all the pullets. I am sure she will never regret becoming a poultry fancier, and I heartily wish her all success.—**WILTSHIRE RECTOR.**

FOOD FOR FOWLS (M. W. C.).—The sweepings of the corn market are usually too fattening. Wheat, peas, &c., are too much so. You will see what we say to-day to another correspondent. Not having a single fact on which to found an opinion, we cannot say why your hens do not lay. If more than a year old, that may be the reason; pullets are more prolific layers than old hens.

BUFF COCHIN-CHINAS (C. D.).—Buff Cochins have qualities that will always make them popular. Many cocks of this breed are bay; but the proper colour is a golden. This, like most correct things, is difficult to attain, and other colours have become so common as almost to form a rule.

GROATS FOR CHICKENS (A. B. C.).—Groats are merely oats, kiln-dried, and the outer coat of the seed removed.

BRAMA POOTRAS (Inquirer).—Brahmas are better table fowls than Cochins. They, in common with other fowls, should be killed at between four and six months, according to season of the year. They are eatable after that age; but they are apt to be strong in flavour. The Dorking is not crossed with any breed. As soon as it is crossed it ceases to be a Dorking.

CHICKEN HATCHING (E. F. G.).—Chickens usually come out of the shell at the end of twenty-one days; but we have known their appearance delayed until the twenty-third day, but the chickens were weak and grew very slowly. From fresh eggs the chicks are usually all out by the morning of the twenty-second day; the strongest get out first. Remove the empty shells and addled eggs, but leave the chickens in the nest for one whole day, feeding the hen and supplying her with water, but give nothing to the chickens; they only require warmth during the first twenty-four hours after hatching.

HATCHING ONE EGG PER DAY (E. B.).—We suppose by this phrase was meant that the incubator will hold twenty-one eggs, and that is the number of days required for incubation.

WINGS OF FOWLS (Inquirer).—The wing-coverts are the feathers that overlap and almost hide them, especially at the shoulder and at the extremities, so that little of the wing is exposed, and that only the middle.

FLOOR OF POULTRY-HOUSE (A New Subscriber).—Either asphalt, bricks, or any other hard flooring, is very injurious to poultry. It bruises their feet and retains wet. Cover the floor 3 inches deep with sand, and rake off the dung daily. Or, a good plan is to have dry earth, and to dig in the dung every third day, for the earth desodorises it, and then the earth may be removed at the end of three months, and used as a manure. Fresh dry earth to be put into the hen-house. The above answer will apply to the query of "A SUBSCRIBER." Sand to be raked only, or loose earth to be frequently dug and changed, are the best flooring.

MATERIALS FOR EGG-SHELLS (Old Cock).—The best supply for laying hens is a heap of bricklayers' liny rubbish. Oyster-shells burned in the fire until they can be easily pounded, are also efficient in supplying calcareous matter for the formation of the egg-shells.

BUCKWHEAT (Brahma).—It is a common field crop in some counties. It is also known as Frank. Whoever told you that it is Indian corn did not know what he was talking about. A little is not a bad food for fowls, but there is nothing better than two daily feeds of barley meal, mixed with mashed potatoes, for soft food, and crushed oats or crushed barley once daily. We never use mixtures the composition of which we do not know.

FOWLS IN SMALL ENCLOSURE (Amateur).—The number of fowls you can keep in the space you name, 20 feet by 10, must depend much on the breed you select. Of Spanish, Brahmas, or Cochins, you may keep two cocks and ten hens. They will require but a small house, say 5 feet of the 20 feet in length, and the whole height of 7 feet. The door, 24 inches wide, to be in one corner; the perches at the other end 2 feet from the ground; three laying-boxes in front of the door; a good large window in the house.

TURKEYS' EGGS BY RAILWAY (P.).—The eggs will travel very well if packed in moss, and there is little doubt of their hatching if they are well managed.

MARKING CHICKENS (Château Vallon).—Adult birds are marked with a ring of brass or iron wire round the leg. That, however, is a disqualification at a show, and must be removed before they are sent to one. A very efficient mark, but one that is not perceptible without handling the bird, is to mark the web of the wing with a hot iron, boring holes through it. This mark never wears out or fills up. Another plan is, to tie strong coloured thread in the web of the wing. This lasts a long time. None of these are perceptible, and, consequently, do not disqualify.

SILVER DORKINGS (Inquirer).—Silver-Greys belong to coloured Dorkings. The hen has robin breast, black and white-striped hackle, grey feathers with white shaft, light grey head. The cock has black breast and tail, light almost white hackle and saddle, metallic bar on the wing on white ground. Silver-Greys have long existed, but it is only of late years they have had separate classes. They are more bred in Scotland than any where else.

FALCH FOWLS (J. Z.).—The Crève Couers were known and kept in England thirty years ago. The La Fleche and Houdan are a modern introduction. We believe the La Fleche and Crève Couers to be better fowls than the Houdan, and more likely to meet your requirements. None of the white-shelled eggs are as thick or as hard as the brown.

BEE-KEEPING (G. P.).—If you send five postage stamps with your address, ordering "Bee-keeping for the Many," you will have it sent free by post. It contains full directions.

FEEDING BEES (G. J. Birmingham).—Now is about the time for commencing spring feeding, and the latter end of April for putting on supers. We place no reliance whatever on the story of honey bees feeding on oil-cake.

HIVES FOR PROFITABLE BEE-KEEPING (A. B. C.).—We consider frame hives to be the best, if you can manage them. Should a swarm issue from a frame hive it is easy, after temporarily hiving it in a common straw hive, to look over the combs in the parent stock, cutting out every royal cell and destroying the young queen or queens if there be any. Having done this, the swarm may be returned by being knocked out on the top of the exposed frames, and will then probably either remain at home altogether, or be so long delayed as to complete the super. We prefer bars seven-eighths of an inch in width for all purposes. To order to Ligurianise your apiary you require a pure Ligurian stock to commence with, and should then proceed as advised by Mr. Woodbury in reply to "W. L." in page 61 of our eighth volume.

ALTERING A NUTT'S HIVE TO A WOODBURY HIVE (A New Beginner).—If you lower your set of Nutt's boxes to 9 inches, and enlarge the pavilion to 14 inches from front to back (all inside measure), it will accommodate eight Woodbury frames, and will form a useful hive without further alteration of the side boxes. In making a new hive we should prefer a pavilion 14 inches from front to back, by 13 inches wide, to accommodate nine frames, and side boxes 13 inches square, fixed with eight bars in each. Whilst altering the Nutt's hive the bees and their combs should be transferred to a Woodbury hive, whence they can be shifted into their former domicile when the alteration is completed. The middle of a fine day in April is the best time for performing the first of these operations. Stewarton hives are made of inch wood dovetailed together, and although painted on the outside, some additional protection is usually afforded them. "Bee-keeping for the Many" will be republished in a few days.

POULTRY MARKET.—MARCH 19.

Our supply is getting less, and the demand increases. Prices have a tendency to rise.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 54.3°; and its night temperature 34.5°. The greatest heat was 75°, on the 27th, 1830; and the lowest cold 16°, on the 1st, 1833. The greatest fall of rain was 1.19 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

TRANSPLANTING LARGE SHRUBS AND TREES.

FEW years ago, when the removal of large trees was more fashionable than it is now, there was some contention amongst the machine makers as to whose apparatus was

best adapted for the work, and a very costly contrivance was exhibited before the late Prince Consort at Chiswick. This was stated to be perfect in its way, but we have heard very little of it since; its merits would seem to be purely mechanical, and its worth as a horticultural implement is questionable. Previous to that the machine of Mr. Barron, with some modification by other makers, was that mostly employed. The work that Mr. Barron had done with it was found to be satisfactory, and trees transplanted by its agency are met with in various parts of England. Previous to Mr. Barron's invention a machine invented by Sir Henry Stenart, of Allanton, was reported by that gentleman and others to have done good service, and contrivances of a like character were now and then met with about forty years ago.

The rage for transplanting large trees having in a great measure subsided, the use of transplanting-machines is, I believe, less common now than it was twenty years ago, although the number of valuable shrubs and trees planted has multiplied exceedingly since then. It is now only in special cases that large trees are transplanted, such as when changes taking place render their removal necessary, and often the success of the operation is not satisfactory; for it is not unfrequently found that after the lapse of half a dozen years a better result would have been accomplished by planting small trees carefully, and encouraging their growth. Occasionally, it is true, the removal of a large shrub or tree will be attended with success, but the contrary is more frequently the case, and the plant operated on dies back for a year or two, and then commences to grow again, slowly if it is an old specimen and removed to a site not so good as its former one, but if to a better the improvement is rarely visible before the expiration of four or five years, perhaps more. Besides, it is only certain kinds of trees that will safely endure the ordeal of transplantation when old; and though it may be all very well to talk of making a place or feature perfect at once by planting large trees, it is better to wait and look at the condition of these large plants twelve months after planting before giving any decision as to their looking well; and, perhaps, a couple of years after that will elicit the admission, or rather confession, that it would have been better to have planted young trees. This is no solitary case, but one of frequent occurrence, and one more likely to happen in some parts of the kingdom than in others, for the very good reason that

certain districts being less favoured than others with rain at a time when newly-planted trees require it, the result is less satisfactory. There is so much difference in the capabilities of trees in respect to transplanting, as well as in climatic influences, that no definite rule can be laid down, unless it be that small plants are more likely to succeed than those which are large; and where the ground is suitable, there is every likelihood of the small subjects out-growing the larger ones in a few years, besides being from the first more healthy and vigorous—a matter often of as much importance as size in respect to appearance. The best results are often obtained when both plans are partially carried out at the same place, a large old specimen being transplanted along with others that are young and healthy, and it would in most cases be advisable, especially where shrubs are concerned, to plant some small specimens near the large; for if the latter do not succeed, the others may, and the object, therefore, will still be attained.

Inconvenient as the removal of large trees is, there are some which are more likely to die than succeed, however carefully the operation may be performed, while others are much more certain to grow. As a general rule deciduous trees or shrubs transplant better than evergreens, and amongst those that do well are such as have their roots nearest the surface. Deep-striking tap-rooted trees are not easy to transplant safely, and one of the worst that I know is the Evergreen Oak; this, even when in a small state, bears the operation badly, and to remove it when it had formed a large tree would, I expect, be very difficult indeed. Hollies that have stood a long time in one place are also not at all easy of transplantation, though they are not worse than Portugal Laurels and some other things; and it is somewhat strange that certain plants having a strong resemblance to each other, and belonging to the same genera, should differ very much in their adapting themselves to the change that transplanting gives them. The common and Irish Yew transplant very well, while *Taxodium sempervirens* is about one of the worst to deal with; *Cupressus Lawsoniana* transplants well, while *C. Lambertiana* is very uncertain. These cases I only allude to as the result of trials with small or moderate-sized plants, but I expect the difficulty will be increased when the specimens are larger. In general the family of *Thuja* transplant well, better than any Conifers with which I am acquainted, but others, of course, may equal them.

It need hardly be said that greater success attends the planting of large trees or shrubs when they have been transplanted two or three years before, or that some benefit is derived from preparing the plant to be removed by cutting its roots all round the year before; but this cannot always be done, as the determination to remove them may not, perhaps, have been formed until the moment it is to be carried into execution. In the latter case, the only consideration is to do the work as well as it can be done, and trust to the weather and other fortuitous circumstances for a good result. Plenty of labour and mechanical contrivance can erect a building of large size in a short time, but the same means, however well directed, cannot ensure

the successful planting of large trees, in spite of all the energy and abilities of the master mind. The removal of a large tree is after all only a mechanical operation, its growth afterwards is a natural one, and no amount of ingenuity can always ensure success. We are occasionally told that trees may be safely moved with a particular machine at all times of the year, and that they will prosper afterwards. I confess that I am myself very doubtful on this point. Some years ago I went to see some trees that had been so treated, and which were pointed out as an example of success, and I did not see a healthy one amongst them, although they had been established some six or seven years in their new abode. The operation, I have no doubt, was well performed, but something must be sacrificed, and there is, consequently, a loss for which compensation cannot easily be made. Some plants that will lift with a good ball, and whose roots are numerous and closely woven together, will remove with tolerable success, but even they suffer a little when the plant is large; while all naked long-rooted ones suffer sadly, and their success is often a doubtful affair. Nevertheless, as it may be deemed worth while to transplant a favourite specimen of large size, and as a costly machine for the purpose may not be at hand, a sort of useful carriage may be made with very little trouble, and the operation performed tolerably well. The mode is this:—

Having fixed on the tree or shrub to be removed, commence on two opposite sides at a proper distance from the collar so as to secure the extremities of the roots; separate these carefully from the soil, turn them upwards, and then tie them out of the way as the work proceeds. Continue this work until you approach so near the collar that the rest may be left intact as a ball; then dig downwards about 15 inches deeper than the bottom of the ball will be. Do this on both sides, and for a space of about 4 feet wide. This done, commence undermining the ball on both sides, throwing the material out of the way.

The carriage, which should be in readiness, is of very simple construction, in fact, merely a flat-boarded platform resting on wooden rollers, the ends of the rollers being shaped into a sort of axle-fitting into holes prepared in the framework supporting the platform, but so low as to take up as little room as possible, in order to save unnecessary excavation to allow of the carriage being brought underneath the ball. It would, however, not be advisable to have the rollers less than 8 or 10 inches in diameter; and allowing an inch or so from the roller to the boards above for dirt, from 12 to 14 inches may be sufficient from the bottom of the roller to the top of the carriage. This carriage is intended to slip in underneath the ball of the tree as soon as the excavation, or rather undermining, is so far advanced as to allow it room.

The two sides of the ball at right angles to those excavated I take for granted have not been touched, and in general these are sufficient to bear the tree when the earth is hollowed out from beneath; and in undermining the ball take care to let the bottom be as flat and smooth as possible, in order that it may rest on the carriage over the whole of its surface. Should there be any roots or unevenness which will prevent this, make up the deficiencies after the carriage is put in by stuffing in some cushions of moss or litter, or it may be soil, only the latter is more difficult to insert.

The carriage being fixed properly underneath, and with its top just touching the bottom of the ball, you may then commence to cut away the two remaining sides of the ball, beginning at a proper distance to save the roots as before, doing both sides together, so that by the time you reach the sides that are cut the tree will settle itself on the carriage. A mat or two tied round the ball will complete the work so far, and some guide ropes should be attached to the top of the tree, to be held till the tree has been fairly drawn out of the hole, which will be more or less easy according to the weight and other circumstances. The tree being on the carriage, the next duty is to cut the ground to the latter, so as to form an easy incline, and to lay a couple of planks on the soft soil for the rollers to run on; then apply hand power in the shape of levers, pulleys and blocks, or some other power, and when it is seen that the whole will move, horses may be put to work; but if the distance to which the tree has to be removed is great, it is best to mount this carriage upon another having wheels, as a waggon without sides, or if with sides the bottom ought to be wide enough to take in the plant-carriage. The top of the tree being securely fixed by tying to the waggon, and the ball made as secure as possible by stuffing and tying, the plant may travel as many miles as you like.

In setting the plant in its future position the mode of pro-

ceeding is nearly the reverse of that already detailed, only this second part of the operation is sometimes more difficult than the first, for it is not always prudent to deepen the hole so much as to allow the full depth of the carriage below the ball, as the latter may accidentally drop into it and be too deep. Where, however, there is a triangle with ropes and blocks, they may be erected over the tree, and the rope fastened to the collar, that being previously well padded. By these means two or three men will bear a great part of the weight, while others are pulling out the carriage, some at the same time holding the ball to prevent its breaking, and, of course, as soon as the carriage is clear of it, let it drop, or rather settle into its place.

Sometimes it is advisable to have two or three loose boards on the top of the carriage before the ball is placed upon it, and these are of great service in sliding the tree off it, the boards themselves being sacrificed. Many better contrivances, however, will suggest themselves to the operator. I have seen a mat inserted underneath the ball, and the whole tied up like a huge pudding; but, in general, this can be dispensed with, and tolerably heavy plants may be lifted in the way indicated. Of course in filling up carefully laying out of the roots must be duly attended to, taking care not to allow them to be together, the whole being spread out as far as possible. Good soil of a suitable kind should then be supplied them. The result will, of course, be good or indifferent according to the character of the season, the adaptability of the tree for transplanting, and some other circumstances, for, be it remembered, I never yet saw a large plant moved without a check, and very seldom a small one. Although I have often enough heard such an assertion made, generally its true interpretation was, that the object operated upon did not suffer much; for, however carefully the work may be performed, and however perfect the tackle, injury must be done to the best roots the tree has, if it be a large one, and has been in its position long. If it be removed to better soil, and a more favourable situation, the tree may after a few years show more vigour and improvement than it would have done if left at its first abode; but this only proves that the situation is a better one, not that the operation of removal effected the improvement.

This paper having extended to a much greater length than I anticipated, I find I must leave the subject of removing shrubs and trees of smaller size to another opportunity, and as much greater success invariably follows the transplanting of small than of large trees, I would in most cases advise planters to be satisfied with such. To be able to point out a large tree that was transplanted without losing a leaf is certainly something to boast of; but it is well to wait and see what the condition of that tree is two years hence. I once heard a pushing builder assert the possibility of transplanting a deciduous tree of large size without losing a leaf, and in the middle of summer, and sure enough he did it, for the leaves were still on at Christmas, but it bore no more, and instances of this kind are not by any means uncommon.—J. ROBINSON.

STOPPING VINES IN POTS.

MR. D. THOMSON in his reply to "ISQUIRER," in the Number of February 20th, and referring to the cutting down of the canes of pot Vines of the same year's growth as a good plan, adds that it is one which he for the future intends to adopt. Now, I have not grown pot Vines extensively, but I always laboured that my few should be good, so far as I could make them so. I tried different plans to secure my object, the best of which was somewhat similar to the system noticed by Mr. Thomson. When my Vines had fully expanded and matured a few fine leaves, I cut them down to the lowest good leaf, and after making a growth of 2 feet, I again stopped them, continuing the stopping at two-foot intervals until I had secured my length of cane. The shoots after each stopping pushed with increased strength, and the eyes below it became much more prominent. The result was, that the Vines so treated carried a better and more regular crop than by any other means which I practised.

My object in stopping was to obtain increased root-action, or in other words to bring a more abundant supply of food to a given point, a system which I had observed to increase the vigour of other plants. After three years' practice the Vines so treated were in every instance the best, and gave the most satisfactory returns.

Some time has elapsed since I practised the above plan. I was not then, nor am I now aware, that there is anything new

in the course; but this I know, that were I again required to grow pot Vines, I should follow the plan here stated.—
J. WRIGHT, *Gardener to the Hon. A. L. Melville.*

SOMETHING MORE ABOUT FRUIT TREE STOCKS.

Mr. Robson, I am quite sure, will allow one who has seen more than most people in fruit-tree culture to notice and correct some of his notions.

The "knifeman," I trust, belongs to a past age. In former days he was a man who employed a sharp knife and a blunt intellect. With the former he "cut back" trees year after year till they were pollarded stumps, and "whip-grafted" trees quickly and dexterously—an operation not requiring much nous. I well remember the old foreman of my grandfather, who was an active man in my youth. He could neither read nor write, yet he was reckoned a good "knifeman," and always boasted of his having grafted a thousand Apple trees per diem for many consecutive days, when a "quarter"—i. e., large piece of crab stocks, was operated upon. He had, he said, a tyer and two puggers—lads who clayed the grafts. This must be "sixty years since." The quarter contained 20,000 stocks, and such stocks as are rarely seen. They threw up shoots from the graft the first season from 5 to 7 feet in height.

The budding of the purple Cytisus on the common Laburnum has never to my knowledge been followed by any stain in the stock in England. The Purple Laburnum, as is well known, was originated in France by the live shield or plate of a bud of the purple Cytisus—the bud having died—staining apparently the common Laburnum in which it was inserted, and thus producing that odd variable tree, the so-called Purple Laburnum. What an imposing name! and what a number of guineas it drew out of the pockets of Englishmen! In the many, many thousands of Purple Beech annually grafted, I have never seen a shoot below the graft, either alive or dead, stained; the same with variegated Hollies and other variegated trees. The way to bring about this staining, if at all possible, is to prevent the graft putting forth leaves. This is easily done by rubbing off the young tender shoots as seen as they appear, so that the graft has a dormant life. The variegated Jasmine has a great tendency to stain the stock it is grafted on; and I think I have seen staining in some other shrub or shrubs, but it is very rare.

Roses huddled on the Manetti Rose stock are not now planted deeply. Rose-growers who are at all worthy of the name huddle them so that the junction of the bud with the stock is within 2 inches of its roots; consequently deep planting is not required; 3 inches deep will do. The growth of Roses thus planted here is remarkable. I have now in sight from my window Rose pyramids, the last year's shoots of which are 9 feet in height. If Mr. Robson ever reads "our Journal," he would know "to whom was due the merit of first trying the Manetti stock for the Rose."

There is nothing new in employing Peach and Almond stocks for the Peach and Nectarine. It was common in France two hundred years ago; but even there they were used only in the dry hot provinces. They have never been common or popular in England, our climate being too cool and moist. The Peach stock is very unfit even for warmer climates than ours; for after a few years the disease called "chlorosis," or as the Americans call it, the "yellows," nearly always attacks the trees. Even trees in pots in orchard-houses in England do not escape this fatal malady. I have never seen it attack trees on Almond stocks, and I have recently told some American friends they should leave off budding their trees on Peach seedlings, and use Almond stocks. The yellows destroys annually thousands upon thousands of trees in the United States, yet I have not heard of the Almond stock being employed to counteract it. I fully believe that in the south of England, in dry, gravelly, or chalky soils, Peaches on Almond stocks would succeed, when those on Plum stocks invariably fail. The knowledge of such things as fruit-tree stocks seems to be but little thought of by men otherwise well up in horticulture. One day they will think differently when their inner knowledge comes—i. e., when they practise with their hands and their heads.

With regard to Mr. Robson's remarks on the Pear on Quince stocks, I can most promptly support what he says as to the comparatively small quantity of fruit borne by a Pear on the Quince stock, and that "there is no instance in which a Pear

so worked has produced anything like the quantity of fruit it has done when grown on a stock of its own kind; and in no case when I have seen it has it approached the majestic growth of the Pear tree when on a stock better suited to its requirements. I have in no instance seen a Quince tree (I suppose Mr. Robson means a Pear tree grafted on the Quince), yield more than one-fourth of what the Pear will do, and this is a wide difference." This is all most true. I have seen in Worcestershire some most majestic Pear trees. I remember one most particularly in the vale of Evesham, which one fine day in September seemed a golden tree, so thickly was it studded with fruit, computed at 100 bushels. The Pears were of a brilliant clear yellow, and most beautiful. Now this was really a "majestic tree." On inquiry I found it was called the Cheat-boy Pear, on account of its often enticing strange boys passing along the roads to pluck the fruit growing on trees, as is usual there, in the hedgerows, and then finding their jaws glued together by its powerful astringency. I have seen other majestic Pear trees; but with the exception of the Aston Town and Autumn Bergamot, of which there is a tree here still alive three hundred years old, I have never tasted a fine Pear from a majestic tree. I think your readers will agree with me, that one or two pecks of Louise Bonne Pears from a well-trained pyramidal tree on the Quince stock, would be of more value for the dessert than a hundred bushels of "Cheat-boys" from a majestic tree, or even twenty or thirty bushels of Swan's Eggs, or "Grey Beurés," a sort which used to be grown here, large trees often bearing thirty or forty bushels.

Mr. Robson, under his peculiarly happy circumstances of not being in the mercantile world of gardening, and of course not knowing much of what is taking place in it, will excuse me for giving him a few words of enlightenment. Such great advantages have been found in France from using the Quince as a stock for the Pear in gardens—a custom, I may add, two hundred years old—that in the French nurseries for a hundred Pear trees sold grafted on the Pear, there are five thousand trees grafted on the Quince, the demand annually increasing. In this country the custom of grafting Pears on the Quince for garden culture has existed not quite so long, and for many years was confined to those skilled in gardening—not professed gardeners, but amateurs. Well, it has gradually spread, till the demand for such trees is very large. Taking my calculations from what passes here, I should say that for fifty thousand trees on the Quince stock sold annually, there are only five thousand on the Pear stock, and as the culture of the former by double-grafting becomes better known, this proportion will soon be exceeded. There is, indeed, nothing more charming than a plantation of Pear trees on the Quince stock, either as bushes, pyramids, or cordons. They never fail to bear if their blossoms are protected. They are always full of blossoms, filling the heart in spring time with that which ought always to come in spring—hope. When I look at my plantation of Louise Bonne Pear trees, some of them twenty-five years old, all standing not quite 5 feet apart, I am annually struck with the pleasant facility of their culture. They are all on Quince stocks, all pyramids some 8 feet high, and are all pinched-in during the summer, so as to keep the trees nicely within bounds. There are about two thousand of these trees, and they stand on a slip of ground less than an acre in extent. Now, the question is, How many "majestic trees" I could grow in this space? Possibly about forty of some such Pears as I have named, worth but little to eat, and less to sell. The forty majestics would, probably, at the end of fifty years bear twenty bushels per tree. The two thousand pyramids on the Quince, after twelve years' growth, bore half a bushel per tree of fine thinned-out fruit, of more than a quadruple the value of the others. No comment is required.

With regard to the culture of Apples—by which I mean their careful cultivation in fruit gardens, not rudely growing large quantities on "majestic trees," we have to thank Mr. Robson for his candour. He says, "I have had little experience with the Paradise stock, and have yet to learn any advantages it possesses over the more common crab." He has all to learn; but, then, placed as he is in a climate and soil the best in England, with a well-appointed large garden, with wall trees, espaliers, and standards, all doing well, and producing more fruit than can be consumed, he has no stimulus to make him gain experience, to try experiments, or to learn whether one stock is better than another. The Paradise stock has been known upwards of a century, and has been largely used by our continental neighbours, who are infinitely our superiors in fruit-tree culture in the open air. It is only within these last twenty

years that it has made much progress in England, owing to that peculiar national dullness in all matters relating to the culture of the soil. We take a new mechanical invention readily enough from our neighbours, but a new idea in gardening is hummed at and haw'd at, till many years have passed and much valuable time has been lost. As with Pear trees on Quince stocks, I must be allowed to go into statistics. Twenty years ago 1000 Apple trees on Paradise stocks supplied the usual demand here; this has gradually increased till 30,000 scarce suffice to do it. The produce of Apples trees per acre on good Paradise stocks would bear about the same proportion to orchard trees on the crab, as pyramidal Pear trees on the Quince do to the "majestic trees," and owing to the trees being cultivated—the ground kept clean, the trees pruned, and the fruit thinned—it is far more valuable. I was offered this week a guinea a-bushel for my Newtown Pippins, grown on dwarf trees on the Paradise stock, by a Covent Garden fruiterer; besides this, the crop seldom fails, owing to the fruit being thinned and the trees not distressed by bearing too many—in short, they may have careful culture, such as it is impossible to give to orchard trees, which, in plentiful seasons, bear too many, and in seasons the converse none. There is nothing "questionable" about the early fertility given to Apple trees on the Paradise stock. They commence to bear the second year from the graft. It is true that such sorts as Hawthornden, Keswick Codlin, and some others do the same on the crab; but such sorts will not supply our desserts or all our wants. No good cultivator would plant a Pear tree on the Quince, unless it was budded or grafted near the surface. It is true that the Quince makes roots near the surface, consequently its stem may be on an emergency buried more deeply than the stems of other trees without injury. With respect to the bearing of Apple trees on a good kind of Paradise stock, if life were not so uncertain, I would wager that twenty trees on it would bear double the quantity of fruit than the same number on crab stocks. Mr. Robson acknowledges to having had no experience in this matter, and yet he makes most confident assertions; this is not prudent in a writer.

No one can admire more than I do a fine orchard of Apple trees, such as one sometimes sees in Kent and in Nottinghamshire, more particularly with Mr. Pearson, whose grandfather and father planted the trees—they really are "majestic," and owing to the heavy demands in a large manufacturing town, where all sorts of fruit are wanted, doubtless pay well; and I confess I fly at higher game, and wish to grow only the finest fruit, such as will command a high price—something in the way of my Newtown Pippins.

At the end of his fourth paragraph Mr. Robson tells us that "We see no instance in which she (Nature) buries the collar below the surface." Nature sometimes tries her hand at grafting in a Hawthorn hedge by uniting two branches, but I never remember her taking budding in hand, consequently she does not, and never has known anything about burying the "collar"—i.e., the junction of the bud with the stock.—T. R.

MR. WILLIAM PAULS SHOW OF SPRING FLOWERS.

On Wednesday last there was opened to the public one of the most charming floral displays which have been seen for some years, a display worthy of one who enjoys a high reputation, not merely as an enterprising nurseryman, but as a scientific horticulturist as well. The exhibitor is Mr. W. Paul, of the Waltham Cross Nurseries, the place of exhibition the eastern conservatory arcade of the Royal Horticultural Society's gardens at Kensington, and the subjects those which are embraced in the comprehensive term, spring flowers.

This exhibition may be regarded in two points of view—first, as an example of tasteful and effective arrangement as a whole; and, secondly, as showing the results of successful cultivation in the merits of the individual flowers. Into the latter it is not our intention here to enter, for a large proportion of the subjects exhibited are the same as those with which Mr. W. Paul has taken no less than twenty-nine first prizes at the recent shows, a fact which is sufficient evidence of their excellence. Those majestic spikes of Hyacinths which carried all before them, reinforced by others equally fine, those Tulips so showy and rich in colour, those gentle Crocuses, and those glorious Rhododendrons, are here in all their beauty; and to these are added numerous miscellaneous greenhouse plants, such as Azaleas, Camellias, Eriostemons, Epacrises, Cinerarias,

Geraniums, double-flowering Peaches, &c. But the Rose, that flower of all ages, and for which Mr. W. Paul is so famed, must not be forgotten; two beautiful groups of it, placed one at each end, serve as the points on which rest the right and left wings of the whole arrangement. Among the varieties are several new ones, such as Dr. Lindley, Elizabeth Vigieron, Glory of Waltham, and Black Prince, several others of the best of the Hybrid Perpetuals, and the delightfully fragrant Teas. The next group, on passing from the conservatory eastwards, consists of miscellaneous greenhouse plants interspersed with flowering-bulbs, and flanked with double-flowering Peaches. Then we have another group composed of Tulips, Hyacinths, and Crocuses; a fourth has masses of rich-coloured Rhododendrons on each side, with three lines of Tulips, and six of Hyacinths, stretching along the centre; the fifth is a mixed group of greenhouse plants, supported on each side by Lilæes, *Bichardia æthiopia*, and tall Scarlet Geraniums; and the sixth, the terminal group of Roses. Opposite the pillars of the front of the arcade a series of semicircular tables are variously filled with *Dielytra spectabilis*, *Cinerarias*, *Narcissi*, *Cyclamens*, Lily of the Valley, and Hyacinths of various colours, edged with either white or red Chinese Primulas.

The arrangement of the groups above briefly described may appear simple, and it has that merit, but it is very effective as a whole; and on inspection it will be found that the details in each group have been carefully studied as regards the contrast and harmony of the colours. The exhibition will continue till the 3rd of April, and besides affording an example which may be consulted with advantage in conservatory arrangement, will afford, it is to be hoped, gratification to thousands during the Easter holidays. To the lovers of fine flowers it cannot fail to do so.

PROPOSED HORTICULTURAL DINNER.

A MEETING was held at Anderton's Hotel, Fleet Street, on the afternoon of Thursday last, to consider the propriety of holding a dinner at some date during the continuance of the International Horticultural Exhibition. Upwards of twenty gentlemen were present; and Mr. William Paul, of Waltham Cross, being called to the chair, the following resolutions were unanimously adopted.

1st. That a public dinner be held during the week of the International Horticultural Exhibition, and that a Committee of Management be appointed to carry out the same.

2nd. That the dinner take place on Thursday, the 24th of May next.

3rd. That an advertisement be inserted in the gardening publications announcing the dinner, and requesting that those intending to dine send in their names at once to the Secretary; and that the price of the tickets for the dinner be fixed at 10s. 6d. each.

4th. That the following persons be a Sub-Committee to carry out the arrangements with respect to the dinner:—Messrs. C. Lee (Chairman), C. Edmonds, B. S. Williams, T. F. Wilding, J. F. Meston, Mr. R. Dean (Secretary).

Several letters were received from leading horticulturists regretting their inability to attend, but cordially approving of the proposal.

DESTROYING THE BROWN WEEVIL.

From your description given to "WATSONIAN" in the *Journal* of February 20th, I am inclined to think that it is the same weevil with which we are troubled. It first begins its depredations in the autumn and spring months by eating away the bark of our young Hollies, Yews, &c., a little below the surface of the ground. It formerly committed sad havoc among our two and three-year-old seedling Rhododendrons; but by annual and biennial transplanting we have almost banished it from our "bog ground." Our mode of proceeding is about the month of May to take up the plants, and give each a slight shake or two, when out rolls from the neck of the plant a white crescent-shaped red-headed grub, about half an inch in length. In June it changes into the beetle or weevil state, which at first is of a white, soft, pulpy matter, gradually becoming brown and hard, when it commences its ravages above ground, in the summer and autumn eating the foliage, and in the spring the buds and bark of our fruit trees, Pears and Plums especially.

If "J. B." will try the following, he may at least save the buds

of his Vines:—Take half a pound of mutton suet, melt it, and while hot mix with it half a pound of chloride of lime, keeping it stirred till it cools, to prevent the chloride of lime settling. Put a ring of this about an inch wide round the stems of the Vines, a little above the surface of the soil. I have used this mixture for the last three years on some thousands of young trees, Pears, Plums, Apples, &c., and in not one instance have I found the weevil cross it.

I find that the best traps for catching the weevils are pieces of rather stiff grafting clay, fitted loosely round the stems, leaving sufficient room for the weevil to creep down between the stem and the clay. Divide the clay on each side of the stem. If these rings are examined every morning numbers of the insects will be found to have crawled underneath after their night's raid.—A NURSERY FOREMAN.

A FEW HINTS ON THE CULTURE OF THE BALSAM.

AFTER having obtained the seed of some variety which has been very highly recommended, and seeing in perspective its beauties developed in summer, nothing is more annoying to the grower of this beautiful plant than to find, after having grown the plants for a month or two, that they must be put out of sight to hide their lanky stems; and as now is the proper time to commence growing them, perhaps a few hints as to their culture would not be unacceptable to some of your readers.

Having procured seed of the Camellia-flowered varieties, if a year or two old so much the better, sow towards the end of March, in light sandy soil, about ten or twelve seeds to a 48-sized pot. Place the pot in a Cucumber or Melon-bed at work, or wherever there is a brisk heat to start them, taking care when the seedlings are up to keep them close to the glass to induce stubby growth. When the plants are 3 or 4 inches high pot them off singly into small pots, using light loam and leaf mould, with a sprinkling of sand. Place them on a hotbed, and keep them close to the glass as before, using a little shade in very bright weather. When the plants have rooted sufficiently they should be kept rather dry and cool for a week or two, which will induce them to show a few flowers, when they can be sorted over, the worthless thrown away, and those with double blossoms and the brightest colours retained. After this the flowers should be rubbed off, and the plants shifted into 32-sized pots, using richer soil than before, and plunging them to the rim in an old Potato hotbed, or something of the sort, where there is a little bottom heat. Keep the lights on, and supply the plants with abundance of water; give plenty of air, syringe them overhead every afternoon, and shut up for an hour or two, tilting the lights a little at night.

As soon as the roots have reached the sides of the pot, and before the plants become pot-bound, shift into the blooming-pots; ten-inch pots are the most suitable for that purpose. Use a compost of two parts friable turfy loam, one of two-year-old dried cowdung, and one of leaf mould and sand. After potting plunge the plants as before, and shade them till established, when the lights should be taken off altogether, except in rough stormy weather. They should be liberally supplied with manure water till they are placed in the house which they are intended to decorate. The flowers should be picked off the main stems should they appear before the side shoots are furnished with buds.

A few plants treated as above will give more satisfaction than a larger number grown indiscriminately, and they will be good plants, and of select sorts; and coming in as they do, when the usual inmates of the greenhouse and conservatory are out of doors, they will be as highly appreciated as they are easily grown.—W. C.

MESSRS. CUTBUSH'S SHOW OF SPRING FLOWERS.

To the admirable display which Messrs. Cutbush, of the Highgate Nurseries, have this year made at the Crystal Palace, as well as to the very superior excellence of the flowers composing it, we have already directed attention. It therefore now only remains to say a few words as to the arrangement.

Along the centre of one of the naves is a double line of tabling, divided down the centre, and 300 feet in length, and on one side of this are arranged about 300 pots of Hyacinths and a like number of Tulips, comprising the best varieties of

those favourite spring flowers—flowers, be it remembered, which can be cultivated by all, which display their full beauty almost before the icy hand of winter has relaxed its grasp, and which, by a little encouragement, may be brought forward to adorn the conservatory, the drawing-room, or the window, even amidst the frost and snow. Of the Hyacinths, it is not too much to say that all the spikes are good, and a very large proportion of them are of a size, and of a perfection as regards form and colour, that no ordinary grower could hope to attain. The Tulips, too, are extremely gay, and had the most showy varieties not been noted as being shown at the recent exhibitions, it was our intention to have named a few of the most effective. They are well worthy of more extended cultivation than they at present receive, more especially as it is not difficult to flower them well either for conservatory or out-door decoration.

On the opposite side of the stage to that on which the Hyacinths and Tulips are ranged is a miscellaneous collection of spring-flowering plants, including some of those already named, Snowdrops, Crocuses, and other bulbs; Dracenas, Azaleas, Kalmias, Rhododendrons, Andromedas, Camellias, Heaths, Epacrises, Acacias, Deutzias, Cytisus, Guelders Rose, Cinerarias, double-flowering Peaches, and the pretty little double white *Prunus sinensis*.

The whole of this excellent display is covered with a new canvas awning prepared for the occasion, and this, whilst it serves to prevent that dwarfing effect which all large structures like the Crystal Palace have upon plants, by the subdued light which it affords, is most favourable to the brilliant colours of the flowers being seen to the greatest advantage.

This exhibition will continue open up to, and including, the 31st instant, and we can commend it to our readers as one that will well repay an inspection.

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE.—New Hyacinths and Roses were on this occasion exhibited by Mr. William Paul. The former consisted of Vunxhaak, Sir Henry Havelock, and Bird of Paradise, to each of which a first-class certificate was awarded; and of Princess Mary of Cambridge, Sir E. Landseer, and Adeline Patti, all of which have been already noticed in recent reports. The Roses from the same exhibitor consisted of Dr. Lindley, large, full, and rich in colour; Elizabeth Vigneron, very large, rosy pink; Glory of Waltham, said to be a fine climbing Rose; and Black Prince, a dark crimson, shaded with black. To this was awarded a first-class certificate. Of Orchids there was a very good display. W. W. Buller, Esq., Strete Raleigh, was awarded a special certificate for a collection in which were *Dendrobium speciosum* with two very fine spikes, *D. aggregatum*, *Vandas*, &c.; and a similar award was made to Mr. Anderson, of Meadow Bank, Glasgow, for cut spikes of *Lycaste Skinneri*, *Odontoglossums*, *Epidendrum rhizophorum*, &c. Mr. Robson, gardener to G. Cooper, Esq., Old Kent Road, had a first-class certificate for *Dendrobium densiflorum thyriflorum*, with an orange lip and white sepals and petals; and from the same came also *Odontoglossum Alexandra*; *O. Cervantesii*, white with some crimson bars; *O. hystrix*; and *O. gloriosum*. Mr. Wilson, gardener to W. Marshall, Esq., Enfield, also exhibited the *Dendrobium* above referred to; and Mr. Willcock, gardener to Dr. Pattison, St. John's Wood, had a special certificate for a collection of Orchids, in which were included *Dendrobium chrysotoxum*, *Oncidium sarcodeis*, *Epidendrum atropurpureum*, an unnamed *Odontoglossum*, *Lycaste Skinneri*, and *Cattleya pallida*. From Messrs. Backhouse, York, came *Odontoglossum luteo-purpureum*, referred to in the report of the Scientific Meeting. Mr. Bull furnished a large collection of new plants, &c. Special certificates were awarded him for a group of *Imantophyllum miniatum* in fine bloom, and for the handsome *Bignonia argyrea violacescens*. *Damara Moorei* received a first-class certificate, and *Camellia Emilia Lechi*, rose-coloured, one of the second-class. Of Chinese Primulas, a fine collection of twenty came from Messrs. Windebank and Kingsbury, of Southampton, who received a special certificate for the collection, and first-class certificates for the following varieties—viz., *P. sinensis magnifica*, rosy pink, very double; *alba gigantea*, large, single white; *filicifolia rubra*, single, very large, glowing rosy purple, beautiful in colour; and *filicifolia alba*, a fine single white. Mr. Toombs, gardener to W. S. Roots, Esq., Kingston-on-Thames, received a first-class certificate for *P. sinensis filicifolia rubra plena*, the first of a new strain of double-flowering Fern-leaved varieties, and as such an important acquisition. The flowers were perfectly double, of a purplish rose, but pale at the edges of the petals; Mr. Shepperd, Bedford, likewise exhibited a variety called *Distinction*, but no award was made for it. From Messrs. Osborn, Fulham, came a yellow *Sinningia*; from Mr. Brown, Emdon Hall, a dozen cut blooms of *Camellias*; and lastly, from Mr. Green, gardener to W. Wilson Saunders, Esq., *Sonchus platylepis*, interesting on account of *Orobanchae minor* succeeding so well upon it; *Nicotiana wigandoides*, loaded with white blossoms; *Maxillaria picta*, *Pleurothallis dichroa*, *Compartmentia rosea*, and other plants of botanical in-

terest. A small standard Wistaria in excellent bloom came, in addition, from the Society's Chiswick Garden.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. The only subjects exhibited were Black Alicante, Muscat of Alexandria, and Lady Downe's Grapes, of which excellent bunches came from Mr. Tillyard, gardener to J. Kell, Esq., M.P., Staamore Priory. They were in very fine condition, and excellent in flavour. A special certificate was awarded them.

SCIENTIFIC MEETING.—Lord H. Gordon Lennox, M.P., in the chair. The award of the Committees having been announced, the Rev. M. J. Berkeley made some remarks on the subjects exhibited. The distinguishing features on this occasion were, he said, the *Amherstia nobilis* and the collections of Orchids, but of these Mr. Bateman would speak. Attention was then directed to *Odontoglossum luteo-purpureum*, exhibited by Messrs. Backhouse; and *O. hystrix*, notwithstanding the difference in the spikes and leaves, was stated to be merely a variety of it. Mr. Berkeley then read a letter from a gentleman, whose name was withheld lest the locality being disclosed collectors might divest it of the plants, stating that in his neighbourhood the Lizard Orchis (*Orehis hircina*) attained great perfection, and in proof instancing one near his house which had a spike 31½ inches in height, bearing fifty perfect lizards. Chinese *Primulas* next came under notice, particularly a double Fern-leaved variety; and the structure of double-flowering *Primulas* being a matter of considerable interest, a paper on the subject would probably appear in the "Proceedings." As an instance of the abnormal production of flowers, a case was cited in which *Clarkia elegans* was found to have produced a perfect flower from the side of a petal. Of *Sonchus ptyloides*, from Mr. Wilson Saunders, it was remarked that it appeared peculiarly favourable to the growth of the parasitical *Orobancha minor*, which, when once established on the *Sonchus*, was very difficult to eradicate. Cultivators experienced great difficulty in endeavouring to grow parasitical plants, but if it were once known which were the plants most favourable to the growth of particular parasites, the cultivation of these would be much facilitated. *Chloranthus incomptus* was mentioned as being very curious in respect to the structure of the flowers, and *Dumora Moorei*, from New Caledonia, as an elegant plant for table decoration. A section of a branch of *Pinus Lambertiana*, from a tree recently cut down in the course of the improvements at the Society's Chiswick Garden, was next exhibited. The branch from which it was cut was pendulous, and then grew erect, and it was remarkable that the distance from the pith to the outside was only ½ inch on the upper side, but as much as 8½ inches on the lower one, being a difference in the thickness of the woody deposit of 7 inches. This result was partly to be accounted for by the gravitation of the sap, but there were other circumstances as well that might exert an influence in causing the great inequality in the thickness of the woody layers on the two sides. A little mollusc, which had attacked Mr. Wilson's Cucumber plants at Weybridge, then occupied attention. This was found to be identical with *Bulimus Goodallii*, a native of the West Indies, although of larger size than the specimens which had for some years existed at a Bristol nursery. It was there mostly found at the bottoms of the Pine-pots, but did not attack the roots; in the case of the Cucumber-plants, on the contrary, it had proved troublesome, and notwithstanding that the house had been thoroughly cleaned and white-washed, and the old soil removed and replaced with fresh, this little snail was as plentiful as ever. Mr. Gwyn Jeffreys, to whom specimens were shown, was surprised to hear of its attacking Cucumber-plants, as the species is considered to be carnivorous, but several instances were known of carnivorous molluscs becoming herbivorous, and *vice versa*. Mr. Berkeley then read a letter from M. Naudin, of Paris, stating that he had found *Cucurbita melanosperma*, an annual at Paris, perennial at Hyères. There was a plant there, five years old, which had a hard stem upwards of 10 yards in length, and even then its growth was not complete. The difficulty experienced in growing some kinds of Gourd in this country was an interesting point in the theory of horticulture, for although the summer temperature at London was nearly as high as that of Paris, yet Gourds were found to thrive better at Paris than near London, whilst at Bordeaux, though warmer than Paris, they were not grown so successfully as at the latter place. The explanation of this was probably to be found in the sky being clearer at the one place than the other, hence that light was as important to their ripening as heat.

The Chairman in calling upon Mr. Bateman to address the meeting on that plant which had been called the pride of Burmah—the *Amherstia*, said that Mr. Bateman required no introduction from him, as that gentleman had contributed so much to the success of the fortnightly meetings.

Mr. Bateman said that before dealing with the most attractive object in the room—the *Amherstia*, and the Orchids, which were his usual province, he would direct attention to an outsider—viz., *Andromeda floribunda*, a plant which in the last few years had risen rapidly into favour. It should be known, however, that it was most poisonous to cattle. His first suspicion of its being so was awakened two years ago, when a goat at Bidulph Grange was seized with what appeared to be an epileptic fit, and in the foamings from the mouth he saw some leaves suspended; but a short time ago, however, two cows belonging to a neighbouring farmer were taken ill with what was supposed to be the cattle plague, and one of them died. On examination

it was found that she had eaten some withered leaves of the *Andromeda*, which had formed part of some school decorations that had been incautiously thrown away within the reach of the animals. Whether dead or alive, no portion of the plant should ever be within the reach of cattle. He did not wish to discourage the cultivation of the plant, but only to inculcate caution as to where it was planted, for it had proved harder even than the Oak, and the flowers, though formed before winter, refuse to expand till spring. Next with reference to Orchids Mr. Bateman remarked that *Odontoglossum radiatum* of Reichenbach, and *O. hystrix*, named by himself, must, he thought, be merged in *O. luteo-purpureum* of Lindley. The disadvantages under which those who first describe new Orchids, often from wretched specimens, labour were then referred to, and as an illustration of the development of such Orchids under cultivation, he held up a small plant of *Dendrobium luteolum*, newly imported, and a fine spike grown by Mr. Anderson, gardener to T. Dawson, Esq., of Meadow Bank, near Glasgow, where there existed a remarkably fine collection of Orchids. Among others there was there a perfectly white variety of *Lycaste Skinneri*—*Odontoglossum Alexandriae*, exhibited by Mr. Robson, gardener to G. Cooper, Esq., was small, but there was one at Mr. Patterson's, near Glasgow, with seven flowers on it. *O. Blantii* was apparently only a variety, for it had been impossible to discover any specific difference between it and *O. Alexandriae*. Attention was next directed to the fine example of *Dendrobium speciosum*, from W. W. Buller, Esq., and though the species had been long known in this country, it was, said Mr. Bateman, evidently still one of the finest, and he called upon Mr. Buller to state the mode of cultivation which he had adopted.

Mr. Buller said he had grown it in a warm greenhouse where *Geraniums* were kept, and the only secret in its cultivation, he believed, was not to shade it at all. Mr. Buller added that *D. Hillii*, which he had recently seen at Kew, appeared identical with *speciosum*, but the latter grew on rocks, the former on trees.

Mr. Bateman, in continuing his observations on the Orchids, said in reference to one exhibited as *Dendrobium macrophyllum*, that a large variety of this had, till the last few years, gone under the name of *D. anosmum*, but that which had been called *D. Dayanum*, introduced by Messrs. Low, was the true *anosmum*. Attention was then drawn to a cut spike of *Agaveum chlorum*, which had been in bloom since Christmas, and of which the beauty had only begun to wane.

The next subject was the special one of the day, *Amherstia nobilis*. Of this Mr. Bateman remarked, that his acquaintance with it began at a very early age, for he remembered reading, when a boy, a newspaper paragraph to the effect that a wonderful flower had been discovered. Little did he then think that forty years afterwards he should have been called upon to speak of that very plant. The paragraph to which he referred appeared about the year 1825. Two or three years later, when at Oxford, he was surprised on opening Wallich's "*Plante Asiaticae Rariore*," to find that the first plate was a representation of that very plant. The plates of it in this work, also one by Mr. Fitch, of the plant flowered at Mrs. Lawrence's, in 1819, were exhibited. The history of its discovery and introduction was this. Some rumours had reached Dr. Wallich's ears from a Mr. Crawford, respecting a tree which had been seen in the garden of a monastery on the River Salcen, in the province of Martaban, and some of the flowers of it were sent to Dr. Wallich. The latter took the earliest opportunity to visit the locality, and when he came to the garden of the monastery, he was surprised to see a tree 40 feet high, bearing long pendant clusters of vermilion-coloured blossoms, such as those exhibited before the meeting by Mr. Taplin. He also observed that the flower was greatly prized by the natives, being found by hand-ful before the gloomy images of Buddha. Ten years elapsed before any other notice was taken of the plant, and up to 1835 no living plant had been seen in Europe. That time was a memorable one in the annals of horticulture, for then the Horticultural Society's collectors were ransacking the world; then Dr. Lindley and Sir William Hooker were in their prime; and then, too, was in his prime the late Duke of Devonshire, who determined *coute que coute*, he would have the *Amherstia*, and he sent Mr. Gibson, now of Battersea Park, to bring it and certain Orchids over. Mr. Gibson succeeded in bringing home, in 1837, a living plant, and a house was specially prepared for its reception; but unfortunately at that time the process of kyanising had just been discovered, and though known to preserve wood, it had not then been also discovered that it had just the contrary effect as regards growing plants. It was, then, placed in a kyanised tub, and year by year grew worse and worse, and seemed so likely to perish that Sir Joseph Paxton had determined to send some one to India to introduce another plant, and was just on the point of carrying that determination into execution when the evil effects of kyanised timber on plants were found out, and the plant was removed from its tub, and thenceforth it began to flourish. Although, however, the Duke of Devonshire was the first to introduce the *Amherstia*, he was not the first to flower it, for Mrs. Lawrence, of Faling Park, in 1849 had the honour of presenting to Her Majesty a bouquet from a plant sent home to her by Lord Hardinge. Since that time the flowers of the *Amherstia* had not been seen, till happening to be at a *sairee* of the Manchester Field Naturalists, he found a spike there, and he was informed by Mr. Taplin, the Duke of Devonshire's gardener at Chatsworth, that it was the last of fifty or sixty racemes that the tree had produced this year. Mr. Bateman added, that the present Duke is so charmed with his *protege*, that he is going to enlarge the house, and

he (Mr. Bateman) would also suggest that the Duke should stretch out his arm to the Andes, and introduce that plant which bears the name of his family, and is said to be the glory of the new world, as the Amherstia is of the old. And here he would remark, in connection with botanical nomenclature, that the honour of having a genus named after one would be more appreciated twenty or twenty-five years hence, for by that time the world would be so thoroughly ransacked that there would be few new genera to be named. Returning to the Amherstia, Dr. Wallich had described it as the most beautiful object in the Indian flora; and just as the celebrated Bonpland, the companion of the still more celebrated Humboldt, wrote after a long imprisonment in Paraguay, that the remembrance of their first botanical excursion was still vivid in his memory, so, too, it was likely that the eye of Wallich to the day of his death still rested on—*Amherstia nobilis*.

[We have seen the Amherstia in the Botanic Garden at Calcutta, and well do we remember the sparkling eye and hilarity of Dr. Wallich as he brought us into the presence of his pet tree. He had had a wooden palisading formed round it to prevent visitors gathering its flowers, and well did the tree merit such care. It was in full bloom, and as the breeze from across the Ganges waved the light pendulous branches, the gentle motions and blendings of the crimson racemes and the long pinnate leaves, rendered it the most brilliant and graceful tree we have ever looked upon.—Eds.]

After a few remarks from Mr. Wilson Saunders on the *Sonchus* and *Orobanche*, it was, on the suggestion of the Chairman, resolved to send the Amherstia blossoms to Lady Sarah Williams, the daughter of the Earl of Amherst.

At this meeting twenty-one new Fellows were elected, and seven Societies admitted into union, among which was the Royal Horticultural Society of Ireland. The attendance at the lecture was extremely numerous, the visitors nearly filling the large Council-room, and altogether the meeting must be considered the most successful of those held this season.

WEEKLY SHOW.—The interest of last Saturday's meeting was greatly enhanced by Mr. William Paul's splendid show of bulbs and spring flowers, which everybody should make an effort to see.

The prizes offered on this occasion were for a collection of six miscellaneous plants, the first of which was taken by Mr. William Young, gardener to R. Barclay, Esq., of Highgate. His collection consisted of forced *Rhododendrons*, *Acacias Drummondii* and *eriocephala*, *Deutzia gracilis*, *Epacris grandiflora*, and *Azalea ardens*. Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, was second; but it must have been a stretch of imagination on the part of the Judges to have regarded four *Azaleas* and two *Pelargoniums* as a "miscellaneous collection," in the sense in which the schedule requires it. Mr. Bartlett, of Hammersmith, exhibited a collection also, which received an extra prize.

In the competition for a collection of twelve bulbs, Mr. Young was again first, and Mr. Bartlett second. Mr. Young received first-class certificates for a collection of Tulips, a collection of Hyacinths, and a tray of very good *Camellia* blooms; and a second-class certificate for mixed bulbs. Mr. Bartlett received a first-class certificate for a collection of mixed bulbs, and an extra prize for a collection of Hyacinths. Mrs. L. Young, of 6, Blenheim Terrace, Kentish Town, exhibited a dozen well-bloomed Hyacinths in glasses, which had been grown in the window of a sitting-room, and received a first-class certificate.

INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS.

The following Hon. Local Secretaries have been appointed in addition to the list already published:—For Leicester, Mr. Wm. Penn Cox; for Huntingdon, Mr. John Ingram, The Nurseries, Huntingdon; for Chepstow, Mr. John Billinger, The Nurseries, Chepstow; and for Redditch, Mr. John Gould, Rose Cottage Nursery. The Right Hon. Lord Lurgan has kindly consented to act as Chairman of the Belfast Committee.

As evidence of the success of organisation of this kind we may mention that the following sums have already been announced by the Secretaries of the places named:—Glasgow and West of Scotland, £127 3s.; Doncaster, £59 8s.; Bristol, £18 18s.; Ascot, £11 11s.; Warrington, £24 3s.; Chelmsford, £63; Coventry, £26 5s.; Manchester, £31 10s.; Oxford, £5 5s.; Derby, £21 1s.; Belfast, £36 15s.; Hertford, £10 10s.; Elgin and North of Scotland, £24 4s.

To show the strong interest the proposed banquet is exciting in the City, we may say that the Right Hon. the Lord Mayor has nominated a Committee of six gentlemen from the Corporation to assist and advise the Banquet Committee, nominated by the Executive Committee of the International Horticultural Exhibition. It is composed of the following gentlemen:—Mr. Deputy Obbard, Mr. Deputy Charles Reed, F.S.A., Messrs. J. E. Saunders, Chairman of the City Lands Committee, John Kelday, Wm. Lawley, and F. Wyatt Truscott.

THE LATE MR. FRANCIS DICKSON, OF CHESTER.

MR. FRANCIS DICKSON, who died at the Upton Nurseries on the 3rd inst., was born at the Nurseries, Leith Walk, Edinburgh, on December 25th, 1793, and was the youngest son of the eminent nurseryman of this name who was the founder of the well-known nurseries of the Dicksons of Edinburgh. The late Mr. Francis Dickson was the last direct representative of that family in the profession. After making himself thoroughly master of the nursery business as practised in Scotland, he went to the then celebrated nurseries of Malcolm, at Kensington, where he distinguished himself by his enthusiasm and love of his profession, and made the acquaintance and lasting friendship of many of the foremost men in the botanical world. After remaining there for a considerable period he returned to his brother, Mr. George Dickson, in Edinburgh, and in the year 1819 came to Chester, where he established the well-known nurseries with which his name was so long and so honourably associated. The collection of hardy plants, and especially of rare herbaceous and alpine plants, which he brought together, was considered at one period to be unequalled. He was the intimate friend of the late Mr. Loudon, and was frequently consulted by him in the publication of his botanical works, as well as by the late Thos. Andrew Knight, Esq., by whom he was nominated, in the year 1825, a corresponding member of the Royal Horticultural Society.

From his earliest years he was an enthusiast in his profession, and his chief delight was in cultivating those plants which were considered the most difficult of management, and in which he was so successful. He was well known for his integrity and uprightness of character. His genial heart warmed with kindly fellowship towards those of his immediate profession who came into contact with him, and his generous hospitality was ever proffered to them. His erect and manly frame gave indication of the vigorous mind it enshrined—a mind stored with great and varied information relative to all branches of his profession. He was borne to his grave in Chester Cemetery on the 8th inst., followed by a numerous throng, who paid in this manner their last respect to a worthy fellow townsman and a valued neighbour. He is succeeded in the management of the business by his two sons, Mr. F. Arthur Dickson and Mr. Thomas Dickson.

NEW BOOK.

A Practical Treatise on the Culture of the Pine Apple. By DAVID THOMSON. W. Blackwood & Sons.

The name of the author, one of the very best gardeners of the British Islands, guarantees that this volume contains no directions that are not sound and tested by experience. He says that his object was to be as "strictly practical as possible;" he has attained his object, and we commend the work to any of our readers who need truthful information on Pine-Apple culture. One or two extracts will give an idea of the contents.

"HOW TO KEEP UP A CONSTANT SUCCESSION OF RIPE FRUIT ALL THE YEAR."

"Where a regular supply of fruit has to be kept up with the least possible intermission all the year round, it is more certainly accomplished by potting a quantity of suckers at frequent intervals. Supposing that a number of Queens ripen in May, June, and July of 1866, these stools will give the suckers that supply the earliest fruiters for 1868. And those that ripen in August, September, and October, give the suckers that will succeed the earliest lot, so that these two sets of early fruiting sorts cover six months of the twelve. The other six months of winter and spring—particularly spring—are those in which Pines are most valued, as other fruits are then scarce. March and April are the most difficult months of the whole year in which to have ripe Pines.

"In June and July I always endeavour to start a quantity of the true Smooth-leaved Cayenne. This is a noble Pine when well grown, being un surpassed for appearance and long keeping after it is ripe, and swells better after October than any other Pine I know. The Black Jamaica is also a most useful Pine for winter swelling, and probably is un surpassed for flavour at the duller season of the year. The Queen is comparatively worthless as a winter Pine compared to these two; it does not swell kindly, and is always dry and juiceless compared to them.

"There should be two sets of Cayennes and Jamaicas, as recommended in the case of Queens and other early sorts, for summer and autumn fruit. The Smooth-leaved Cayenne is so very shy in making suckers that I always endeavour to save as many crowns as I can, and take all the suckers that can be got in October from the fruiting plants, whether the fruit be ripe or not. These suckers and crowns are potted generally into six-inch pots, and shifted in spring as soon as sufficiently rooted, as described in the former part of this treatise. These are

shifted into 11 and 12-inch pots, and grown on in the usual way, only that they are not kept so dry in autumn and winter as is desirable for early-starting plants. The temperature, too, is kept 5° higher than for *Queen's* at rest; the object being not to ripen, as it were, the growth of these so as to predispose them to start in spring. The heat is quickened, both top and bottom, in February, and they make a spring growth; arrested in May and June by being kept drier and cooler; and then, with increased heat and moisture, I rarely ever fail in starting them all in June and July. Care must be taken that they never get too dry at the root, particularly in spring, as that would be likely to start them before this is required. This applies with the same force to *Jamaicas*. These will keep up the supply of fruit till the end of the year.

It is necessary to have a later lot of these two varieties to come in for spring, and this I find rather difficult in the case of the *Smooth Cayenne*. It makes suckers still more tardily from late plants. The method I generally adopt is to save the old stems of those that ripen their fruit through the winter, and place them in strong bottom heat to spring the latent buds. These grow into nice plants, ready to shift into eight-inch pots in September, and I shift these into their fruiting-pots in March, and by pushing them on they start in September and October, and succeed those started in June and July. For this purpose I most decidedly give the preference to the *Cayenne*; and from plants of it so managed, I have had very fine fruit in the spring months. They are kept on at a temperature of from 60 to 65° all winter, with a steady bottom heat of 80°.

There is nothing peculiar in the management of these winter fruiting sorts, except it be that I never keep them so dry and so completely at rest in winter as those intended to start early. This is with the view of their not resting and maturing themselves so thoroughly in autumn and winter as would cause them to start when excited in spring. The *Smooth Cayenne* requires more moisture at the root when growing than is good for most other sorts. It is also more impatient of bright sun early in the season than any I know, more especially if kept gently on the move all winter. And rather than allow the foliage to become bronzed, shade should be applied for a time, as already directed. When swelling off in winter, water at the root will of course not require to be so frequently given as in summer, and there should be no syringing. The evaporating-trays will keep the air sufficiently moist. Air must be put on for a short time in the middle of every fine day.

With respect to the treatment of plants that fail to start into fruit, Mr. Thomson says:—

"When I have room to conveniently operate on these I cut the plants over at the surface of the soil, and strip a few of the leaves off them, and pot them deeply and very firmly in fruiting-pots. They are slightly shaded for ten days, by which time, with a brisk bottom heat, they begin to send out wonderfully strong roots, and then the shading is discontinued, and they are watered. In this way they are transformed into dwarf strong plants, and I always find they start into fruit very soon after, and swell off fine fruit."

LOBELIAS, VERBENAS, AND ZONAL GERANIUMS FOR BEDDING.

In reply to a query from "Nemo" in your Number of the 6th inst., I write to say that I sowed a packet of *Lobelia* Snowflake about six weeks ago, and though the seeds were a long time in coming up, yet I have now about fifty or sixty plants above ground.

I sowed four kinds of *Lobelia* the same day—*Blue King*, *Paxtoniana*, *Speciosa*, and *Snowflake*—with very different results, though they were all treated alike. *Paxtoniana* coming up very freely and quickly, and *Blue King* next. *Snowflake* was a long time before it made its appearance. I am inclined to think that at this time of the year persons are apt to give many seeds to great heat and moisture, which they cannot stand till the days are longer, and there is more light. Small seeds, too, like those of the *Lobelia*, will not germinate if they are covered with too much soil. I always mix my seed with Calais sand previously to sowing, prepare a pan, smooth the top soil, and water it, then scatter the sand with the seed mixed in it over the top; the white sand helps very much to show where the seed falls, and to sow it evenly. I never cover it any more, but put a sheet of glass over it, and place it near the light in a temperature not exceeding from 50 to 55°. *Lobelia* seeds with this treatment scarcely ever require any more water till they are up.

A few words with respect to *Verbenas*, which seem according to some accounts to have kept badly this winter. The only kind I have seen really showing signs of disease is *Mrs. Holford*, and I have seen traces of disease on that for two or three years in several different gardens. Last September was too dry and hot for *Verbenas*, and, unless cuttings had been secured previously, it required a great deal of care and management to secure a healthy stock of plants afterwards. No plants are more easily injured by over-dryness at the roots,

I have known many a healthy pot of fine established cuttings permanently injured by one day's exposure to a drying sun after the pots were dry. Many gardeners are too much afraid of the watering-pot for *Verbenas* in the winter. My own experience is, keep them always slightly growing, as near the light as possible, give plenty of air underneath the stage, and water and syringe regularly, but always allow a little fire heat to dry off superabundant moisture from the leaves. With this treatment, and by nipping back the shoots whenever they are more than 3 inches long, *Verbenas* may be kept healthy and strong, without green fly, mildew, or thrips, and will supply any amount of cuttings in the spring.

I agree with Mr. Kent that it is a great pity that *Verbenas*, with the exception of *Purple King*, are so much neglected; it is often, I think, from want of attention, and because they are difficult to winter without proper care, and will not stand the treatment that the *Zonale Geraniums* have to live through. The following sorts all bedded well with me last year:—*Craor*, *Firefly*, *Foxhunter*, *Mrs. Harrison*, *Madame H. Stenger*, *Nemesis*, *Ariosto*, *Mrs. Elphinstone*, *Sultana*, *Ocean Pearl*, *Miss Field*, *Brilliant de Vaise*, *Purple King*, *Géant des Batailles*, *Garland*, and *Shades of Evening*. Of these, *Foxhunter*, *Miss Field*, and *Madame Hermant Stenger* have rather too straggling a habit, but the flowers are very perfect of their kind. *Nemesis* is so like *General Simpson* that I consider them the same, and the *General* was first in the field.

The following *Verbenas* are also, I consider, well worth growing for mixed beds, and I hardly know any bed that is more effective or more interesting than a mixed bed of *Verbenas*:—*Apollo*, *Mulberry Superb* (*Lady V. Scott* or *Miss Trotter* synonyms), *Mrs. Mackay*, *Black Prince*, *Lord Leigh*, *Lord Craven*, *The Moor*, *Reine des Violettes* (useful in colour, but bad-shaped frass), *Evening Star*, *Miss Hammer*, *Rubens*, *Mrs. Pennington*, *Silver Star*, *Tyrian Prince*, *Cicero*, *Lady Cotton Sheppard*, and *Victor Emmanuel*. This number might be increased by many of the new striped sorts, but I have not tried them, and therefore cannot form an opinion of them as bedding plants. I only had a few of them in large pots in a cold frame last year, but I intend to give them a trial this summer.

While on the subject of bedding plants I wish to add that I am going to make an experiment this year with all the new sorts of *Zonale* bedding *Geraniums*, both *Noseway* and others, which I can obtain. I have Mr. W. Paul's new seedlings and several others of Bull's, Carter's, &c. Those of which I have only a few, I shall plant in large mixed beds, and, including old sorts, I have more than a hundred to try. If any person wishes any seedling or other *Geraniums* to be tried alongside of the older-established sorts, and also with some of the new sections from Donald Beaton's, I shall be very happy to try them and report on them. With your permission I will send you a report in the autumn of the results of my experiments. I wish to see which of the new sorts will stand the test of being planted side by side in Yorkshire with the older-established sorts, as *Tom Thumb*, *Trottingham Rose*, *Stella*, *Crystal Palace Scarlet*, &c.—C. P. CLEAVE.

TEMPERATURE-RECORDING APPARATUS.

In the spring of last year I purchased one of Negretti and Zambra's maximum thermometers (a cheap one on boxwood is the kind necessary for the purpose)—a thermometer where the mercury remains in the graduated portion of the stem on the slightest fall in temperature, and thereby shows the maximum heat attained during any given period. Now, any one who has such a thermometer in his possession will perceive that on tilting the instrument, bulb uppermost, the mercury detaches itself from what remains in the bulb, and the portion of the stem near thereto, owing to the obstruction in the tube, which prevents the mercury retreating into the bulb on a decrease of temperature. It occurred to me, therefore, that the portion of mercury detached could be made use of, if means were devised for its measurement. Such a thermometer as I have described, where the obstruction is caused by compression of the glass tube and not by a piece of glass or enamel, when placed in a vertical position, acts as an ordinary thermometer; the mercury from its weight always passes the obstruction in the bent portion of the tube, and the reading of actual present temperature is obtained. If, however, the thermometer be tilted from the vertical position, the mercury will detach itself at the bent portion and run down to the farthest end of the

tube. Assuming that at a given time the thermometer can be so tilted by clockwork (as I will hereafter show to be the case), how is this quantity of detached mercury to be measured? in other words, when a person comes to his thermometer some hours after the portion has been detached, how is the temperature which was existing at the moment of separation to be ascertained? The portion of mercury detached must be measured, and the measurement is made in this way: Suppose the mercury when the thermometer is placed in a vertical position, bulb downwards, stands at 50°, it will be found on tilting the thermometer and detaching the mercury for experiment to the other end of the tube, that the upper surface of the detached portion will read off at or near some of the degrees on the ordinary scale of the thermometer. On the opposite side of the graduated part of the instrument a small slip of paper must be fixed by glue or some similar adhesive substance along the whole length of the tube. Should a thermometer, when placed vertically, read at 50°, care must be taken to note the height on the paper where the detached portion of the mercury appears on tilting, and note that spot 50° likewise. This plan is to be adopted at different temperatures throughout the scale, and by such means the temperature when the thermometer is tilted and reversed can be ascertained, or such a scale can be engraved by the maker. The instrument is reversed at the time that is desired by means of the weight of an alarm clock. As the weight descends, the thermometer which is in connection with it, is made to fall to a position considerably below the horizontal. I purpose now to give drawings of a

thermometer both before and after it has been set in motion by the alarm clock, with the machinery also which reverses the thermometer, and by such drawings I hope to convey to your readers a much better idea of the thermometer apparatus than I have done by the past description.

I have only cursorily glanced at this invention; but sufficiently, I think, to give your readers an opportunity of judging how far such a thermometer apparatus may be useful to them. I have no doubt but that many already possess a maximum thermometer, such as I have described, and most, if not all, a small alarm clock with weights. That is really all the machinery required for the apparatus in its simplest form. The working of thermometers which register the maximum and minimum is well known to all. In the morning the observer knows how low or how high the temperature has been during the night. My plan will not tell him when the lowest or highest temperatures occurred, as is the case when a photographic apparatus is used, but it will give him the temperature of that moment when the alarm descended, and the alarm must be set for the time when he wishes to know existing temperatures. I think in many instances that such knowledge will be of use to a gardener and others, and will give them respectively information how fires have been working up to that fixed time, whether proper temperatures were then existing in a room, or the degrees of cold or heat in the external air, and that not by getting up in the middle of the night, or by being on the spot by day, but by reading off by the new scale the height at which the mercury stood when the weight of the alarm ran down.

Fig. 1.

A. Piece of wood. C C C. Conorse of thermometer. H H. Hooks. M. Height of mercury in tube. N. A nail. O. Obstruction in tube. S S. String. W. Alarm weight. X. Hook to alarm. D M. Detached mercury. Y. Part of thermometer inverted, with new and old scale.

Fig. 2.

In choosing a thermometer for the purpose great care must be taken to see that the mercury does by its own weight easily pass the obstruction in the tube when the instrument is placed in a vertical position, and also that, when the thermometer is tilted, the mercury detaches itself without difficulty at the point of obstruction and proceeds to the farthest end of the tube. This previous caution is necessary, for unless the mercury acts in the way above mentioned (although such an instrument is perfect as a maximum thermometer), it will be of no use for recording temperature at any one given time. I now proceed to describe the temperature-recording apparatus.

Figs. 1 and 2 represent the invention in its two different stages; the one (fig. 1) a moment before the alarm has gone off, the other (fig. 2) when the weight of the alarm has descended and the thermometer is no longer in the same vertical position as before.

I will now glance more particularly at the general machinery necessary to carry out such a change, and, first, I will describe the mode of setting up a thermometer as it appears in fig. 1.

Against the wall of a greenhouse fix (secure from dripping of water), and set going a clock which is furnished with an alarm weight, w, at the bottom of which is a small hook, x. I will suppose the time at the moment of starting the pendulum and winding up the alarm to be 6 p.m., and that the temperature

of the place at 12, midnight, is required to be known. Set the alarm for 12, midnight. In the wall drive in or screw hooks at h, h, and at x fix a maximum thermometer which plays freely on a nail, x. Connect the thermometer with the alarm weight, w, by means of a string, s, s, s, fastened to the hook, x, and passing round the hooks, h, h. The instrument now acts as an ordinary thermometer, the mercury stands up to m, and passes the obstruction at the bulb, o. As the temperature varies, so will the mercury rise or fall in the tube; but at 12, midnight, the scene will be changed. The weight, w, will descend; the thermometer turning on x, as on a pivot, will pass through c, c, c, and will present an appearance similar to that observed in the second drawing, fig. 2. Now, what has really taken place? A quantity of mercury has been detached at o, and has run down to the end of the tube, marked n m (detached mercury). The instrument cannot run down to a lower position than that indicated in fig. 2, owing to a small piece of wood, a, which prevents the weight, w, descending farther. This will be better understood if the reader look at the position of a as represented in fig. 1. Care must be taken also to see that the mercury has run down to the end of the tube before reading off the degrees of temperature by the new scale, x, which represents part of a thermometer inverted with the mercury run down. Should an increase of temperature have taken

place after midnight a portion of mercury will be found deposited at the bulb end of the tube; but this quantity is not to be taken into account. At the moment of tilting, the thermometer is supposed to have stood at 38°, as is shown by the new scale. All that is required to reset the instrument is to pull up the alarm weight, w, in the usual manner, and the apparatus will appear once more as in *fig. 1*, and be ready for future observations, according to the fancy of the observer.—*X., Surrey.*

HEATING A SMALL PROPAGATING-HOUSE.

Will you inform me as to the best manner of making a small tank for propagating-purposes, as cheaply as possible? I have a small greenhouse, 15 feet by 10 feet, with a door leading into a potting-shed. The front shelf is 2 feet wide. I have enclosed a portion, 5 feet in length, with glass, and have had made a small tin boiler, placed in the shed, with pipes 1 inch in diameter, placed horizontally, running into that enclosed portion of 5 feet. These I have covered with cinder ashes, and I find I obtain a nice bottom heat of 80°, but only just where the small pipes run. Now, would it do to make a small wooden or brick tank half filled with water, covered with slate, on which the pots could rest, and through which the tin flow and return pipes could pass round inside?—*ARDENT LOVER OF FLOWERS.*

[Your cheapest plan would be to add two more of your one-inch pipes in the enclosed space. Make the bottom waterproof with Portland cement, place house slates or galvanised iron over your pipes, and then ashes for plunging in. Leave a few holes with tubes in the covering, to let up heat when you want it, and through them you can let air or moisture down at pleasure. Your two one-inch pipes, unless very hot, and that always wastes fuel, will not give you enough of continuous heat, either for your present arrangement or if you preferred a tank. The piping recommended would also be necessary for a tank; a wooden one would be cheapest. It should be made of 1½ to 2-inch wood; 3 inches would be deep enough; slate would be the best covering. At that depth you would want a frame with glass to set over it. Your first plan is the simplest.]

CULTURE OF VINES IN POTS.

(Continued from page 221.)

THE nine-inch pots being full of roots, pot the canes without loss of time into 15-inch pots, which will be large enough for the majority, but any that are very strong may have 18-inch pots, and those of small growth 12-inch pots, for though all may have been put in at the same time, and treated alike, the canes will have different degrees of strength. The pots should have one large hole at the bottom, and three, each an inch in diameter, in the sides, the bottom of these holes being slightly above that of the pot. A large crock being laid over the hole at the bottom, place 2 inches of rather large crocks over it, and above these an inch of smaller ones, but not very small, and on these again an inch of the sods broken into pieces with the hand, and the soil knocked out of them. The pots are now ready for the Vines. The soil being chopped with a spade, and made somewhat fine, mix with every peck one quart each of half-inch bones (boiled), and pieces of charcoal, from the size of a hazel nut to that of a walnut. Mix them well, and in this compost pot the Vines, pressing it firmly between the ball and the sides of the pot. The soil should not be wet, nor yet dry, but between the two extremes, and it should have been kept under cover for some time to air. After potting, if there is the convenience, a bed of leaves and dung, or tan, will be of advantage in inducing the roots to reach the sides of the pot quickly, and its temperature should be from 70° to 75°. Upon no consideration must the Vines, for the sake of bottom heat, be placed in a situation shaded by other climbers. As climbing Vines require the first place beneath the glass, and they should be from 9 inches to a foot from it, and a foot apart, or better 18 inches. The pots may remain plunged to the rim until the roots reach the sides, when the pots should be raised, and remain plunged no deeper than a couple of inches above the side holes. Through these roots will come, and passing into the fermenting material give, without applying liquid manure, to the canes a strength more than equal to that obtained when the pots are on a hard bottom and liquid manure freely given. If the pots are slightly plunged in a border, weak liquid manure may be afforded twice a-week, but if on a hard floor or bottom it should be sup-

plied at every alternate watering after the roots show at the sides of the pot, as they will do in three weeks after potting. When the pots are on a hard bottom there is an advantage, inasmuch as all the roots are made within the pots, whilst when plunged many of the best roots are in the bed, and these on the removal of the pots are lost, and unless the pots are plunged in a mild hotbed on forcing, the Vines show the loss by breaking weakly. If there is the convenience to form a hotbed in which to plunge the pots before forcing, allow the Vines to root through, as they then require less feeding to become strong, and I do not like to be under the necessity of giving strong doses of liquid manure in order to have strong canes, for it makes the soil heavy. On the other hand, if there is no alternative but to set the pots on a hard bottom, be content with giving weak applications of liquid manure at every alternate watering, and what is lost in the thickness of the canes will be gained in their certainty of fruiting.

From the canes being trained to the roof they will throw out laterals near the bottom, but trained to a stake erect few if any will appear at the bottom. If not trained to the roof, incline the canes after the last potting as nearly to a horizontal position as convenient, remembering that the more erect the canes are, the more their vigour will be spent in the upper part, and that is the part to be cut away, and along with it the best eyes. Laterals, however, will show, and I wish to have them as low upon the canes as possible, and for that reason train them to the roof or inclined from the perpendicular as much as circumstances will permit, for I have a great aversion to a cane double the strength at 8 feet that it is at 2 feet from the pot. Encourage the laterals near the bottom, and do not stop them until they have made three leaves, then take out their points; but stop those above 5 feet from the pot at the first leaf, removing the tendrils when first seen, to avoid the strength of the cane being wasted. After the laterals have been stopped once, allow them to make six leaves, taking out the point of the cane when it has grown 9 feet, and every time the lateral from the side of the upper eye makes a leaf take out the point of the shoot above that. If the uppermost eye break, as it most likely will, and the next two or three below it, stop all at the first leaf, and this will cause the vigour of the Vine to be thrown into the laterals below, and these being allowed to grow, and hang loosely so as not to shade the first leaves along the cane, this will be of nearly equal strength from top to bottom.

When the vigour of the Vine seems to have spent itself, which will be known by the laterals giving up growth, and the wood of the cane assuming a russet appearance, reduce the laterals to six leaves, and if they do not break within ten days reduce them still further to one joint from the point whence they take their rise; but if they push strongly stop them at the first fresh leaf, and instead of reducing them all at once, do so by degrees until they be all brought in to one joint, and at this keep them until the wood is brown and hard; then with a sharp knife remove them close to the cane. This must not be done until the wood is ripe, and the roots in the border cut off close to the pots, and the soil in these sparingly supplied with water; for if it be moist, and the root-action powerful, to take away the laterals is only to cause some of the principal eyes to break, and fruit may be showing at a time when the Vines are required to go to rest.

From the time of potting the eyes to that of the wood becoming brown, the soil should never be allowed to become so dry as to cause the leaves to flag, but be kept well supplied with water; but this should not be given until the soil shows signs of dryness, which, after the pots become full of roots, will be every day, and very often twice a-day water will be required to keep the leaves from flagging. After the canes have become as thick as the little finger, and the wood is turning brown, leave off the applications of liquid manure, and only water when the soil is dry. Up to this time weak liquid manure may be given at every alternate watering after the pots have become full of roots. Discontinue watering after the leaves turn yellow, but do not leave off all at once, but from once a-day gradually reduce the frequency of watering to once or twice a-week, which will be sufficient after the leaves change colour, and then the Vines may be taken out of the house and placed close to a south wall with the pots on boards, there they will soon go to rest.

The house, until the wood become brown, should be sprinkled morning and evening with water, and the paths, walls, &c., must be kept moist, and if there are evaporating-troughs these are to be kept full of liquid manure. The foliage should be syringed every evening to prevent red spider attacking the

principal leaves, for unless these are kept free of this pest the eyes at their axils will not be properly matured. The moisture and the syringing should be continued until the wood is becoming brown and hard, when both are to be gradually discontinued.

Air is to be given freely, fully, and early, as from a deficiency of air and light the canes will be long-jointed. Give air then early, and particularly whilst growth is being made, for if ever the wood become long-jointed, no amount of air and light afterwards will remedy the evil. It must, however, be given without lowering the temperature, and the amount should be reduced before this fall much, so as to afford a rise of a few degrees after the air is taken off for the day. A little may be left on all night, but currents of cold air should at all times be avoided; and when the thermometer shows less heat a short time after air is given than before, it is an indication that too much has been admitted. Either it was given too late, or it was not needed. Air day and night should be given after the ripening of the wood begins, and it should be more freely admitted then than when the canes are growing.

The temperature up to the time of the wood turning brown, and the completion of the growth, should be 65° at night, or rather in the morning, from 70° to 75° at mid-day without sun, from 75° to 80° on cloudy days with clear intervals, and from 85° to 90° on clear days. After the wood has turned brown, and the growth is on the decline, the temperature should be 5° lower at night, and this should be rather from leaving more air on than from keeping the heating surface cooler. By day the same temperature should be maintained, for hot days and comparatively cold nights favour the thorough ripening of the wood.

The eyes being inserted during the first week in January, and treated as above described, the Vines will be ready for their final shift in April, and by the end of August the wood will be of the thickness of the little finger, brown, and hard. They may then be placed close to a south wall, where the leaves will soon fall, when the canes are to be cut-in to 6 feet. If the eyes are not inserted until the first week in February, and grown on as already mentioned, the canes will not be strong enough for their final shift until May, and will not have the wood brown and hard until September. In this case they should not be taken out of the house, but kept in it, trained near the glass, and when the leaf falls they should be pruned. The first description of canes will be eligible for forcing in the November and December following, in order to yield fruit in April and May, whilst those of the latter description should not be started before the days begin to lengthen.—G. ABBEY.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE operation of surface-stirring amongst advancing crops must be persevered in. *Beans*, earth-up growing crops. *Broccoli*, sow the Purple Sprouting and Lee's New Early White Sprouting. *Cabbage*, sow for the main autumn crop the Enfield Market and the Battersea. *Capsicums*, pot-off as soon as they are fit. *Cauliflowers*, stir the soil round those under hand-lights, and earth them up. Sow the Frogmore for an autumn crop. *Celery*, prick-out the early crop. *Cucumbers*, earth-up during dry weather, and give air freely, preserving the heat by fresh linings if necessary. *Kidney Beans*, put in a small breadth of the Dun-coloured or Fulmer's on a warm, dry, sheltered border, and plant a quantity in small pots, to be raised in a cold frame, and planted out as soon as all danger of frost is over. *Potatoes*, the main crop may now be planted. *Spinach*, sow small crops of the Round in drills, but little at a time, as it soon runs to seed. *Tomatoes*, these should now be potted off. *Sea-kale*, see that the ground for this, *Rhubarb*, and *Asparagus*, is in readiness to be planted soon. These require a deep rich soil, which should be trenched 2 feet deep, plenty of rotten manure being well incorporated with the bottom spit; indeed, the ground can hardly be made too rich, particularly for *Asparagus*. This, when planted in well-prepared soil, is very productive, yielding a large number of fine strong shoots every season; whereas if planted on poor shallow soils no after-attention in the way of surface-manuring or watering with liquid manure will serve to secure first-rate heads, and it is so much esteemed in most families that the trouble and expense necessary to properly prepare the ground should not be complained of, particularly as beds rightly made

last for many years. Sow seeds of *herbs* and other vegetables that may have been omitted during former weeks. Remove all litter and weeds. Earth-up early crops, strewing a little soot about them to prevent the attacks of slugs.

FRUIT GARDEN.

The season for disbudding fruit trees is fast approaching. The importance of this operation is generally acknowledged, and upon the proper performance mainly depends the production of a suitable quantity of healthy clean wood of a fitting quality. Take, for instance, a single branch of a Peach tree when it first starts in the spring. If in a healthy fruit-bearing condition it will throw out probably fifty wood shoots, and perhaps a greater number of blossoms: if the whole of these were left on it is probable that two or three of the leading shoots would, by drawing all the nourishment to themselves, become rank and overluxuriant, whilst the remainder would be weak and worthless; the fruit, too, would be small, ill-flavoured, and a great portion of it abortive: hence the necessity of a systematic course of disbudding, by which we mean the entire removal of every fruit and every shoot that is not required to be brought to perfection, and if this system of disbudding be rightly carried out through the whole of the tree, it will induce that proper equilibrium of the sap by which the trees are prevented from growing into overluxuriant wood. Every tree in a good soil is capable of producing and bringing to perfection that quantity of wood and numbers of fruit which are proportionate to its age and the healthy condition of its roots: consequently, if by carefully thinning the fruit and removing superfluous wood, the sap is directed to all parts of the tree at nearly equal distances, the result will be that each individual shoot will have the power of drawing to itself that amount of sap which is necessary to its healthy support. In order to have fine trees it is necessary to begin with them from the time of planting, and the selection should always be made with care. Those only are worth planting which are well filled with clean healthy wood from the centre to the circumference; if they are not so, they should be closely headed back until they have formed good heads. Supposing the tree to be operated upon to possess from eight to twelve branches of young wood springing from the centre, the object proposed to be attained is that the branches may not elongate themselves to a greater circumference, but produce healthy branches from the centre; and this is attained by removing, at four different thinnings, every shoot but the terminal one and the one nearest the base on the upper side of the shoot. If this were done all at once the trees would be injured, but from being done at intervals, the shoots to be left acquire sufficient strength to absorb all the nourishment the tree can give, and the sap being thus equally distributed, no shoot will be able to take to itself an undue preponderance. We have entered into this subject more at length on account of the great show of blossom on fruit trees this season.

FLOWER GARDEN.

Proseute vigorously, till finished, improvements of every description. Bring speedily to a close the digging and raking of borders, sowing grass seeds, laying down turf, and the planting of evergreen and deciduous shrubs. Make new plantations of Russian double blue and white Violets. For this purpose select the young runners, but give the preference to seedlings of the Russian Violet; they make stronger plants, and flower more abundantly than offsets.

GREENHOUSE AND CONSERVATORY.

Now that the new growth has commenced, abundance of air and light should accompany it, if short-jointed wood and healthy foliage are to be obtained. To allow sufficient air to greenhouse plants, with the keen piercing winds we are now experiencing, requires some management, for with a bright sun air must be supplied freely. Hardwooded plants, whose pots are full of roots, and which it is not convenient to repot just at present, should be carefully attended to with water, for if allowed to flag, many plants, particularly such as have fine hair-like roots, scarcely ever recover. The growth of plants intended to bloom next autumn and winter will require attention: if numbers are grown they will be easier managed if placed by themselves. The early-started Chinese Azaleas will be making growth, which should be encouraged by frequent syringing and a genial temperature of about 50° by night. Straggling shoots should be at once removed; and to obtain perfect flowering specimens, the growth should be uniform to enable the wood to ripen at the same time. Some of the earliest-bloomed Camellias may be added, and occupy the shady parts of the house.

Epacris is another useful family for winter flowering, and will stand a moderate forcing. To the above may be added various plants, which, if required to bloom at Christmas, should be encouraged to make an early growth preparatory to an early ripening and rest. The potting such of the above as require shifting is best done after the growth has become somewhat matured. Prune in *Erica hyemalis* and other winter-blooming Heaths as they go out of flower, to be in order for potting. *Puchsias* will be benefited by the application of clear liquid manure. Very liberal shifts will be necessary at this period, more especially with those intended for very large specimens. *Cinerarias* for late blooming should be shifted. See that the twiners which are starting into growth are kept free from insects, as these, if allowed to get a footing upon the young tender shoots, will soon do a vast amount of mischief. *Mandevilla suaveolens* is one of the most beautiful and useful of twiners; but it is subject to the attacks of green fly and thrips when commencing its growth in a cool house, and unless these be eradicated, they will greatly retard its growth and prevent its blooming early. It almost rivals the lovely *Stephanotis* itself in beauty, and is not much inferior to it in fragrance, and it grows and blooms as freely in the conservatory as the *Stephanotis* does in the stove. It requires, however, to be kept dry at the root during winter, and should not be encouraged to start into growth early in spring. In a close-roofed conservatory it will be one mass of bloom from the middle of July till November.—W. KEANE.

DOINGS OF THE LAST WEEK

KITCHEN GARDEN.

Our ground is still too wet for much seed-sowing, except it be Peas and Beans. If it do not dry soon, we will sow lots of vegetables under a little protection, and prick off afterwards. The Peas covered with ashes, &c., were soon found out by an army of pheasants, and we had to cover them thickly with branches, and then will not if that will not do. On Tuesday we planted out a lot of Peas and Broad Beans several inches in height, working in the nice friable soil about the roots, sticking as we went along, and placing some laurel twigs on each side of the row as a protection. If we had known there would be so much snow on Wednesday, and such a frost on Thursday morning, we would have delayed the operation a little longer; but the young plants have sustained no harm, and we expect will succeed well. The pheasants have not meddled with them as yet, and they seldom do when well-established. Without any protection they will of a morning before one is out clear whole rows of those only lately sown. They like the Peas best just when swelled enough to enable the radicle to protrude, as then, no doubt, they are very sweet. Except the regular looking-after of other vegetables to keep all right, and providing for successions of Kidney Beans, Rhubarb, Sea-kale, Mushrooms, &c., there has been little doing in the kitchen garden.

Contrary to our wish, we have taken up some more Sea-kale, as the cold weather has given a check to that out of doors, protected merely by pots and a little litter. It is, however, showing freely, and therefore, we will not take up much. In addition to what is under pots, we will shut up a piece with banks of litter a foot in depth on each side, and on these place hurdles thatched with evergreens, and then covered with litter, to keep out the light. The hurdles will be easily moved so as to permit of the heads being readily seen and examined, and cut when 6 or 7 inches long. It would be of little use placing hot litter about the roots out of doors now, even if we had it. Boxes would be better than the hurdles, as they would be cleaner. The litter placed over the hurdles must be clean, or the heads of Sea-kale may be disfigured.

Gave plenty of air to Radishes, Lettuces, Cauliflowers, Potatoes, &c., in suitable weather, and in a dry day in the beginning of last week ran the hoe or fork through winter Onions, Spinach, and Cabbages, and raked the ground over Asparagus that had been dressed with rotten dung, burnt earth, ashes, &c. If we had a little salt we would have slightly whitened the ground, which serves to give the Asparagus a little encouragement when starting, and also keeps down weeds. Prepared some ground for Asparagus, Sea-kale, Rhubarb, Artichokes (Globe and Jerusalem), and got forward as much as our stiff moist soil would permit.

Dressed the outside of the frames intended for Cucumbers with coal tar, as described last week. Run the tar on the

bottom of the frame outside, and let it seep down a little in the bed and lining. Made the soil turn against the sides of the box all round inside, to prevent the slightest fumes from the tar entering, for nothing will stand that with impunity. We hope this will keep rats and mice at a distance. Planted again with strong plants. This avoids one of the instances of the disappointments that gardeners often experience from hosts of enemies, notwithstanding all suitable precautions.

FIELD EXPERIMENT.

Pruned and matted in favourable weather. Forgot to notice last week that Peach with the leaves on made a good protection for wall trees if put on thinly. As then stored canvas is the best where it can be obtained. The orchard-blossom trees are standing very well; those in the first house are in full bloom at the back, and it is shut up earlier to guard against cold nights. In this we have an old iron stove, which we can light on an emergency. This is placed more for convenience of position than suitability as to draught, and yet a little fire in it does wonders. Contrary to all our experience and knowledge in such matters, the outlet-pipe goes horizontally 7 or 8 feet before rising upright outside the house, and this gives a little trouble when the wind is from the north. In any other direction the draught is good enough, and a great heat is thrown out in the large place from little fuel. Were such houses our own, we would have a good brick stove in each, a horizontal pipe a foot or 18 inches long, and then an upright pipe free of the glass. That it might not be in the way against the back wall, we would place it in the middle of the house, partly sunk, with an open space all round it, and take the upright funnel through the roof, substituting a stout square of galvanised iron with a hole in it, for the usual square of glass. As stated last week, for merely keeping frost out from rather small places, but roomy, there is no other plan so economical in first cost, or that will use less fuel afterwards to produce the desired result, provided the draught is duly regulated by a close-fitting ash-pit door. Most people run away with the idea that for any purpose, be the house never so small, heating by hot water is the most economical, as well as the best. We own at once that for all places it is the best mode for diffusing something like an equality of heat; but we contend that to heat a small single house by hot water involves the loss of a good deal of heat up the chimney, however carefully the damper and the ash-pit door may be attended to.

Heating by Gas.—Besides what appears in answers to correspondents, many inquiries reach us as to the practicality, utility, and economy of the plan. In every case we reply, we have had little or no practical experience, but we have paid considerable attention to the subject, and seen what we could of the plan when in operation. The result is the conviction that such a mode of heating is chiefly applicable to small places, such as the neat little conservatories that in suburban districts often abut against the folding-door window of a sitting or drawing-room. These may easily be heated by gas-burners passing through tubes, or first heating a small boiler to which pipes are attached. We recollect of a neat little house thus heated that abutted against the folding-door window of the sitting-room. The kitchen, &c., was beneath this room. In a corner in the kitchen, not far from the ceiling, a black-tin boiler was fixed, about the size of a teakettle, but hollowed-up or concave at the bottom. A strong gas-burner was placed beneath it, and a tin cover when the gas was lighted went over all, with means of regulating draught when the pipes became hot. The pipes were also of black-tin 1½ inch in diameter. Two of these were sufficient to keep out frost, except in severe nights, and then a late fire was put on in the parlour and one of the doors left open. The place altogether was about 7 feet wide, 11 feet long, and 10 feet in height. This simple apparatus would have done very well with soldered joints, if it had been kept constantly at work, but though painted the metal rusted inside when not in use, whether the water was left in or taken out. The proprietor told us that ultimately when the pipes were out he should use two or three one-inch stout iron pipes, and most likely do away with the boiler, and allow the heat from the burner to go at once through the pipes, and then out of the house by means of a small gas-pipe. The place could have been comfortably heated from a close kitchen boiler, but the head of the kitchen would not hear of it, and the master considered he had better not try to conquer her prejudices. Success by all such modes will be very uncertain, unless the manager of the kitchen fire be made a firm ally, and then all will be plain sailing.

Again, there are many who have a greenhouse close to or

near their house, heated sufficiently to keep the plants all right, but who want a little place warmer, shut in by glass, for propagating, seed-sowing, &c. Now, in such a case, a jet of gas, either with or without a boiler, will often do all that is wanted. One of our correspondents to-day has set off a place 2 feet wide and 5 feet long for such a purpose, and has had a small boiler made and two-inch pipes connected with it, to heat that little place, shut in with glass for this purpose. If gas could have been obtained it might have saved a good deal of labour, and the waste of fuel that is complained about in heating such a little place separately. For such a purpose, were we near enough to a kitchen boiler whence once a-day, if necessary, a painful or two of water not far from the boiling point could be taken, we would have a stout wooden vessel made of the necessary length and width, and about 3 inches deep, covered with slate or sheet iron, and that with sand or ashes for the pots. We would have a funnel placed at the top of this vessel, and a tap or plug at the bottom, the latter to remove the cold water, and the other to put in the hot water, which would seldom require to be oftener done than once a-day, and in mild weather not so often. In such a wooden box, with no outlet for the heat, except to the pots, and that, too, covered, the heat is retained a long time, and under such circumstances it can be regulated to the greatest nicety, by taking in some cases part of the cooled water away, and everything would be as thoroughly under control as if gas or hot water were used. Of course, such a plan would only be applicable to small places. For nice Fern-cases, plant-cases, and propagating-boxes, in parlour windows, there is no more simple plan for heating them, and perfect cleanliness may be secured if ordinary care be used.

There are inquiries as to how to keep Peach trees in unheated houses longest in bloom. Our first reply is, Keep them as backward and in as dry an atmosphere as possible. Our next would be, if you let them come early, by early shutting up, &c., then you should try some simple plan to prevent them suffering from cold. We cannot agree with "W." that a lot of Peach trees in full bloom is the most beautiful of all sights; but we do allow it is a very beautiful one, and so is an Apple tree in full bloom, and hence the fruit-grower has a great advantage over the mere flower-grower, as he has the beauty and the utility together.

Regulated and stopped Vines, and attended to other houses such as detailed in previous weeks. Have been obliged to move Strawberry plants from a vinery where they were becoming too much shaded. They neither set nor swell well without plenty of light, and if they do swell in plenty of heat, and a little shaded, the flavour is never anything to boast of. In full light Keens' will be as firm and nearly as black as the Black Prince. In shade they come flabby and too pale red in colour.

ORNAMENTAL DEPARTMENT.

Went on potting, repotting, sowing, pricking-off, and giving general attention to what needed it, as detailed last week, and of which we shall have more to say next week. See Mr. Keane's directions last week about Orchids, &c.—R. F.

TRADE CATALOGUES RECEIVED.

James Service, Corberry Hill, Maxwelltown, Dumfries.—*Descriptive Catalogue of Florists' Flowers, &c.*
 J. C. Padman, Providence Nursery, Boston Spa, Tadcaster.—*Catalogue of Dahlias, Hollyhocks, and Miscellaneous Bedding Plants.*

COVENT GARDEN MARKET.—MARCH 24.

THERE has been scarcely any alteration worth notice, the demand and supply being about balanced. There is no difference in the continental imports. Pears and Apples for dessert are limited to those varieties lately mentioned; and forced Strawberries are coming in very good for so early in the season. We hear great complaints of the appearance of the outdoor ones, many of the market gardeners having ploughed them all up, as they showed no trusses. We should be glad to know if this is at all general.

TO CORRESPONDENTS.

EVERLASTINGS (Mrs. W.).—We think you have seen *Helichrysum orientale*, the Immortelle of the French, which is dyed of various colours. Many species and varieties, however, are treated in a similar manner.

BALA-PHOOL (B. Godbold).—Bala is the Hindoostanee name for the *Hibiscus tortuosus* of Roxburgh. Phool, in the same language, is a flower. Mats and small cordage are made from the fibres of the bark.

BED IN ROYAL HORTICULTURAL SOCIETY'S GARDEN (L. F. S.).—The plant you describe we believe to be *Colens Verschaffeltii*; the corresponding bed on the opposite side was *Amaranthus melancholicus ruber*, edged with *Centaurea candidissima*.

WINDOW GARDENING (C.).—If you send ten postage stamps with your address, and order "Window-Gardening for the Many," you will have it sent to you free by post from our office. After reading that, if you need further information we shall readily give it.

CRANSTON'S GREENHOUSES.—"A. M." wishes to know what rolling blinds, or sun-shades, are most suitable for these; and at what distance they should be from the glass so as not to interrupt the ventilation.

ORCHIDS FOR COOL GREENHOUSE (An Old Subscriber).—The twelve orchids you name for a cool greenhouse, with an average temperature of from 50 to 60°, with a rise from sun heat—namely, *Laelia anceps*, *Cypripedium insigne*, *C. barbatum*, *Maxillaria Harrisonii*, *M. graminifolia*, *Dendrobium nobile*, *D. Koenigianum*, *Cattleya Mossii*, *superba*, *C. Skinneri*, *C. crispata*, *C. Forbesii*, and *Lycaste Skimneri*, *Oncidium glossum*, *Acridos odoratum*, *superbum*, *Bryasia vertucosa*, *major*, *Calanthe vestita*, *Cattleya Mossii*, *superba*, *C. Skinneri*, *Coleogyne cristata*, *Cypripedium barbatum*, *superbum*, *C. insigne*, *Dendrobium nobile*, *Phajus grandiflorus*.

HEATING A CHURCH (F. F.).—We have most faith in your proposed plan of heating the church by a saddleback or other boiler. The objections as to excavating, &c., do not apply where there is a basement story. In some cases, when the lower storey was used as a schoolroom, a good-sized furnace boiler—that is, a stove with water all round, without any brickwork, did for heating the school and the church above. We have known many churches made very comfortable in winter by lighting the gas a couple of hours before service. We have no doubt that the church could be heated by gas and a boiler as you propose; but then, as we have only seen small places heated by gas, we would not at present be inclined to think that we were considering the economical in using gas to heat a boiler 5 feet long, about 81 or 9 inches in diameter, and supplied with twenty-seven tubes of copper inside, 1 inch in diameter each, and the attending piping. The cap with the small pipe to allow the gas to escape are all very well, and the form of the boiler for the purpose we consider also to be good, being simply that of the letter L reversed, with the short leg over the burners, and the long leg horizontal; but with our present lights we rather think the consumption of gas to heat that boiler and about 1200 feet of three-inch piping would be such as to make some church officers stare. Very likely, however, you may know more of heating large places by gas than we do; all we know is, that the simplest boilers generally do their work best. We shall be glad to know the expense of such heating.

POTTING CAMELLIAS (Jas. Keay).—In potting those received from Germany with turf, the soil or peat in which they grow may be picked away from amongst the roots, being careful not to injure them; but beyond picking away the loose soil and loosening the sides of the ball, the roots should not be further disturbed, for nothing is more brittle and sooner injured than Camellia roots.

DESTROYING MOSS ON A LAWN (H. W. W.).—Wood ashes and gypsum, because they promote the growth of grass, are good destroyers of moss. It is mainly due to the porousness of the ground. Apply a dressing of rich compost, say one-half well rotted manure, and the other half good rich soil, well mixed, first scratching the surface with an iron rake, which will remove much of the moss. Use enough to cover the ground from a quarter to half an inch deep. Now is a good time to apply it. About the middle of April rake the ground again with an iron rake backwards and forwards, and this will again remove much of the moss, also any sticks or stones; and then, on the first prospect of rain, sow over the lawn the following:—*Festuca duriuscula*, 2 lbs.; *Festuca tenuifolia*, 1 1/2 lbs.; *Poa nemoralis*, 2 lbs.; *Cynosurus*, 4 lbs.; *Trifolium minus*, 2 lbs.; and *Trifolium repens*, 4 lbs. in mixture for an acre. After sowing, gently rake over the ground, and roll immediately. The ground should be dug at the time of sowing, and if rain fall on the following day, or soon afterwards, the seeds will soon vegetate. The lawn will please before autumn. If you object to the appearance, which will not be long barren-looking, though it will be so at first, you may give a dressing of guano in the first showery weather in May, and again in July, and this will promote the growth of the grass and the destruction of the moss.

GARDEN PLAN (C).—There is nothing in your plan to induce us to incur the expense of engraving it, and especially as no planting is stated.

FIXED OR SLIDING SASHES.—*B. B. D.*—If you have no openings in the back wall you had better have movable sashes 1 foot wide at the top of the roof. For a stove, four of these 18 inches long and a foot wide would do. The rest of the roof could then be fixed. We are presuming that you could have also ventilation in the front wall. The chief advantage of a fixed roof is its economy, otherwise movable roofs are better, especially if you can slide with a view to employ the house for different purposes.

VINES BEING KILLED.—*J. Brown.*—If troubled as some of us have been with very dry summer, we think it very likely the roots of your Vines have gone a good way too deep. If so, most likely the covering the border with fermenting material, as you have done, and a little more fire heat in the autumn, will make the Vines again vigorous. In another year without lifting the roots, though that eventually may have to be done. Perhaps your heavy crops may have been too much for the Vines, and a lighter crop may restore the lost balance. We have several times noticed the effects you detail from very heavy cropping.

HEATING VARIOUS HOUSES BY ONE FURNACE.—*Patelin.*—1st. It would have been your best plan to have had the boiler in the middle, between the two houses, and then you might have heated both together or separately. 2nd. By the plan proposed you cannot heat one house without heating the other. 3rd. You cannot have the bottom heat for one house or for both on the plan you propose, as your return-pipe, dipping into the water, is much below the bottom of the boiler, and no pipes act well if below the bottom of the boiler. 4th. With your stop-valve at z, you may heat the bottom beds of one or both houses, but only provided that the lowest of the pipes are not lower than half the height of the boiler. They would do if not lower than the flange at the bottom of the boiler, but they would do better if the return-pipes in the houses were not lower than the top of the boiler. 5th. In section x, called present state, the return-pipe is shown a long way below the level of the boiler. Even with air-pipes we have seldom known such a plan to answer well. 6th. Except this sinking of the pipes, we have no fault to find with your proposed plan either for bottom heat for one or two houses. The stopping of the valves at z will, and the heat into the bottom-heat pipes; but the less the bottom-heat pipes go below the level at x the better they will act. 7th. We do not know from your description whether it would not be possible to have your bottom-heat pipes on much the same level as the top-heat ones, which would be the best under the circumstances.

SOIL FOR PAMPAS GRASS.—*A. New Subscriber.*—The Pampas Grass delights in a deep, rich, and moist soil. We know some plants of it that would scarcely grow; they were taken up with good balls, the bottom of these loosened, the soil taken out to the depth of 18 inches for a yard all round, and replaced with turfy loam, well rotted manure, and leaf mould, in equal parts, well mixed. In summer a good dressing of liquid manure was given in dry periods, and the result was that they grew amazingly. We recommend a similar course to be pursued with every Pampas Grass that has been planted more than three or four years. The difference in the growth of the plants is due to the richness or pooriness of the ground, and their being supplied with water or allowed to suffer from drought.

COCONUT FIBRE.—*Subscriber, N. B.*—The fibre of the coconut is not suitable for any kind of plant. It is very different from the dust which is the waste of the cocoa fibre mat, brush, and rope maker. The refuse of the husk is the kind suitable for compost for plants, and it is like mahogany sawdust. In its fresh state it is one of the best of composts for Orchids, and may be used for them in place of brown fibry peat, to which it is equal, if not superior. In its fresh state it is excellent for mulching plants in pots or tubs, and also for surfacing flower-beds. For potting plants it is best laid up along with other soil, or by itself, for a couple of years to decompose, and then it becomes closer in texture, and resembles mould. In this state almost anything will grow in it. It is used in place of heat for Ferns, for all plants that require peat soil, and for softwooded plants in place of leaf soil.

CYPERUS ALTERNIFOLIUS VARIETAS CULTURE.—*Dull Fellow.*—By semi-aquatic is meant that it requires abundance of water during the growing season, and should then be kept with the soil wet, or the pot set in a saucer full of water. We have not found it do well in a warm greenhouse, though it may do so with others who treat it differently. With us it requires a winter temperature of not less than 50° at night, but does better in one of 55°. In winter, or when not growing, the soil should not be more than moist. We find that a compost of equal parts of sharp sand, peat, and loam, with an inch of sand at the top, suits it well. In rich soil the leaves become green, and in a greenhouse the plant dies. Unless kept wet at the root, and in a moist atmosphere, it scarcely grows, and is eaten off by red spider. The green-leaved species is a greenhouse plant, but the variegated form is more delicate than the original.

Tobacco Seed.—I grew a hundred weight last summer, and some of the plants were 8 feet high. An old plan remarked it was much finer than in its native country. I should have no objection to sending my correspondent a packet of the true seed of Nicotiana glauca for twelve postage stamps.—*THOMAS ELGOM, Gardener, Blon Garden, Near Curwen, North Wales.*

MELON VEGETABLE MALLOW.—*G. J. W.*—It was advertised by Messrs. Small, Colnbrook Nursery, Slough, Bucks.

TRICHOOPSIS GRANDIFLORA LEAVES BECOMING SOFT.—*(A Subscriber).*—The cause of the leaves turning soft is the atmosphere not having been for some time sufficiently moist, and from the temperature being too low. Having no pseudo-bulbs, this class of Orchids will not bear the dry heat in which many others will thrive.

ANTS IN ORCHIDHOUSES.—*Idem.*—If they have their nests in the floor or other parts of the house away from the plants, water them daily with ammoniacal liquor from the gas-works, and they will disappear in a few days; but if they are in the pots, or where ammoniacal liquor cannot be used, your best plan will be to mix together equal proportions of honey and arsenic, placing it thinly on saucers or paste-board near their haunts,

JERUSALEM ARTICHOKE.—*Alfred Crockett.*—We are unable to account for your Artichokes not boiling soft. We may help you by stating how we grow and cook them. The ground is dug deeply in autumn, and a dressing of half-rotten farmyard manure applied. In February, if the weather is mild, and the ground in good working order, or on the first favourable opportunity, drills are drawn from 4 to 6 inches deep, and 2 feet 6 inches apart. In these the medium-sized sets or tubers are planted at 1 foot apart, and the soil is drawn over them. When the stalks are 8 inches or so high, soil is drawn up to them as in earthing-up Potatoes; the after-treatment consists in keeping down weeds, which are not very troublesome in Jerusalem Artichoke plantations. A sheltered yet open situation is selected. In autumn, after the stalks are leafless, we dig up a portion to serve for a month's or six weeks' consumption, and store them away in moderately dry sand in a rat-house, which is a shed at the back of the garden well closed on all sides. Our soil being dry, we do not mind taking up more than enough to serve a month or so, and more to save trouble in taking up in frosty weather than for any other reason. When grown in strong ground they are best taken up in November or December, and stored away in sand; but if the ground is light they keep more plump in the ground. The tubers are cooked as follows:—They are well washed, pared, and put into the pan with the water boiling. They are boiled for half an hour, and are then strained, placed in a dish, and served with melted butter. In some cases they are fully cooked or boiled in twenty minutes. Ours are never hard, and we have grown them in eight different soils and localities.

PLANTS FOR EXHIBITION.—*J. Threlfall.*—The following are first-rate, and nearly all of them are very constant:—Leah, deep golden yellow; Ne Plus Ultra, bronzy rose; Charlotte Doring, white ground, edged and tipped with rosy crimson; Lord Derby, rosy crimson; Andrew Dadds, dark maroon; Bob Billey, red; Miss Henshaw, white; Anna Keynes, white, tipped with lilac rose; Willie Austin, buff; Criterion, delicate rose; Lilac Queen, lilac; and Beauty of Hilberton, purple.

ONE CHIMNEY FOR TWO GREENHOUSES.—*(N. C.)*—We have no doubt that the flues would do better if you had a separate chimney for each; at least, if they were a separate chimney for part of the height. A friend of ours had a greenhouse heated by a flue which communicated with the parlour chimney, perhaps some two yards above the fireplace, but it was a perfect nuisance, as when the fire was lighted the parlour was filled with smoke. The flue was carried up outside, so as to enter the chimney about 10 feet higher up, and there was then no more annoyance. But for having another chimney, not it would be better not to go into the house chimney at all. Many chimneys in a house, if they terminate on the same level, out-side even, will swirl smoke into the next chimney, and it will come down and fill the room. We have no doubt that another chimney will remove your smoke nuisance—that is to say, if there is a good draught in your flues.

GROWING PINE APPLES.—*Miss Hughes.*—To learn the whole method of culture, purchase "The Pine-Apple Manual." You can have it free by post from our office for thirty-two postage stamps.

BOOK.—*F. E. L.*—Paston's Botanical Dictionary is out of print.

GARDEN PLANS.—*(A Gardener).*—There is no such work as you inquire for. We are now preparing one for publication. You had better refer to the back volumes of this Journal. They contain many such plans.

GARDENERS' WAGES.—*(H. S.)*—We cannot annotate upon communications which have not appeared in our own columns. We are always ready to refute mis-statements wherever they appear.

EARTHWORMS.—*Woodlice (R. M. T.)*—Earthworms do no harm to flowers beyond drawing seedlings into their burrows. Toads will eat woodlice.

BRICK AND DRAINING-TILE MACHINE.—*Miss Langford.*—We do not know which is the best.

LEARNING GARDENING.—*(J. W. B.)*—You ought to obtain employment under some head-gardener at a gentleman's residence, and then try to obtain an engagement at some large public establishment. The only way for you to proceed that we can suggest, is for you to advertise for what you desire.

CYCLAMEN (S. S. L.)—The leaf sent belongs to *Cyclamen neapolitanum*, and to that variety cultivated as *Cyclamen africanum* (latifolium, robustum, and macrophyllum) superfluum. The flowers are a shaded red, foliage large and hand-some.—*G. A.*

NAMES OF PLANTS.—*(J. L.)*—We cannot undertake to name plants from leaves only. 2, *Gnaphalium tomentosum*; 3, *Cineraria maritima*; 5, *Centaurea rugosius*; 6, *Polycterium alaicorne*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 24th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

NOTES FROM MY POULTRY JOURNAL.

EGGS IN WINTER.—While reading a late Number of THE JOURNAL OF HORTICULTURE I noticed the number of eggs given by three hens and five pullets during the winter months as instanced by a schoolboy, and your remarks thereon as regards feeding. Perchance a lady's experience in the same school may be equally interesting to your readers; and they may perhaps profit by what I tell them of my little yard when the dark wet days of winter come again, the time when the bright coral colour is so apt to leave the comb, and the clear, ringing, morning crow, that should make the hills echo, sounds like the creak of a raven.

Well, on the 10th of last December I turned out in my yard ten pullets and two hens—viz., six Spanish and six Light Brahmas, with a Black Spanish cockerel. My yard is a space 14 feet square, in which the hen-house, 4 feet square and 7 feet high, is built entirely of wood, placed upon joists with the ground taken away underneath, thus leaving a free space for air all round and under the house. Two small doors, slung on hinges at the top of the hen-house, are aids to ventilation, and a little latticework in the front gable end admits, day and night, pure air when the doors are closed. The floor of this hen-house is kept covered to the depth of an inch or two with ashes, which are sifted carefully every morning, thus rendering it clean, sweet, and free from vermin. The nests are separate boxes placed in each corner of the house. The yard has a border all round, 2 feet in width, planted with laurels and other evergreens, the ground beneath being covered with green turf renewed every fortnight, over which the fowls in fine weather love to walk and trim their plumage, cackling under cover of the shrubs. The yard is of fine gravel, with a high mound of the same in the centre for the fowls' scratching and eating. The fence enclosing the yard is of galvanised wire netting, 6 feet high, supported by iron posts, and has one door, with strong wooden posts and frame, for admission to the yard and hen-house. All is thus under lock and key.

Now for an incident which may serve as a warning to others. I had not roofed my yard over. My fowls came in the afternoon, and all-desirous of their comfort, I turned them into the yard, and fed them for the first time with my own hands. They were very quiet, and I left them, of course thinking they would naturally seek the shelter of the hen-house at roosting-time; but fancy my horror and affright when, in less than an hour, my maid came rushing to me with the news that my valuable fowls "were up in the trees like so many crows." Never shall I forget it. A fall of sleet had set in, and everything was wet and sloppy, but there was no help for it. What a hunt it was catching them! and oh! the looking up in the trees, with the snow and rain drizzling down my face, and the wind, and my ribbons; but at length we were rewarded, though the gardener had to climb the trees for the last two. When all were safely shut in the hen-house we soon threw wire netting over the yard, drawing it tight to the iron uprights, and binding it with wire.

After this all went well for a time, and eggs began to come in. I fed the fowls according to my usual régime, to which I shall allude by-and-by; but the weather became so miserable, raining day and night, and several of the birds had begun moulting heavily, and their consequent tenderness made them so susceptible of damp and cold, that my utmost care would not prevent their becoming sickly. That beautiful gloss, like the sun on a gipsy girl's hair, left the Spanish plumage, and the delicate pencilling of the Light Brahma faded away in wet and dirt. I saw plainly something must be done to help them. I at once determined to make them a nice dry day run, where they would have sufficient protection from rain, and wind, and wet ground, and yet enough of liberty. I therefore erected alongside the hen-house a wooden building, 10 feet long and 4 feet wide, thus running parallel with it; a door opening outside the henyard, so that I could pass in and out of this covered building without going into the yard. It is all of wood, with strong plate glass windows in an asphalted roof. The front, down to within a foot of the ground, is of galvanised wire netting, which, however, can be closed in by shutters during heavy rains and severe cold. This building communicates with the hen-house, and the floor is covered 6 inches deep with fine old mortar rubbish, the surface of which is raked and sifted daily. This was finished by February, and since the fowls have

had this retreat there has not been an ailment amongst them. They are all in the most perfect health and feather. They are as sleek as moles and eat like hunters, and up to the 10th of March, thus including the three winter months, have laid me 236 eggs. I do not boast of this as a great number; but when I remember that all the Brahmas moulted during the time, and the damp and cold of the season, I am satisfied with the result.

So much for housing them; but after all, as you say, there is a great deal in the mode of feeding. I like a generous diet for fowls as well as for children. In the morning I give my thirteen fowls one pint of Indian corn and barley mixed, a plate of boiled potatoes, and about six spoonfuls of Tyler's patent meal mixed with water. Then I place in the building a large cow cabbage, which is always entirely devoured by four o'clock in the afternoon, at which time they are fed again with the same quantity of mixed corn and Tyler's meal, and about 3 ozs. of barleymeal in paste. About every second day they are allowed 2 ozs. of meat saved from the table, and cut very fine. I always take great care that the birds have fresh spring water in clean garden saucers twice a-day, and I believe there is nothing more conducive to their health.

In keeping all live stock it should be, I think, our constant endeavour to subject them, as nearly as we can, to the great guiding laws of Nature. We should enable them to employ their instincts, such as running under cover in rain, and dusting themselves. We should give them imitation bowers, and food which assimilates as nearly as can be to that which they would gain in the wilds. Then their animal life would become pleasant to them, and their various functions natural and not matters of pain; and we should have our reward, if not in the return they made, at least in the observation of their perfect health and thorough enjoyment.

I am about rearing chickens, and if you care for my experience I may tell you by-and-by how I progress.—L. W.

RAILWAY CHARGES.

I SENT to the late Rochdale Show a basket containing a cock and hen Buff Cochins, tied with another basket containing a cock and hen Sebright; also two other baskets tied together, containing each a Game Bantam cock and hen. All the baskets were directed *via* Peterborough. In the freight-note of the Great Eastern Railway the charge for carriage to Rochdale stands thus:—

To Rochdale, one basket 12 lbs. each	s. d.
" " 30 lbs. "	2 0
	4 0
	6 0

On the 7th of February the baskets began to come back.

On the evening of that day arrived the Cochins; on the morning of the 8th came the Sebrights; in the afternoon one basket of the Game Bantams appeared; the fourth basket I received on the following morning. All the baskets were marked *via* Peterborough, yet two travelled by the London and North-Western Railway. For three I paid; for the fourth no charge was made. I have this day a demand sent up from our station for 3s. 6d. for a basket of birds from Rochdale, delivered on the 8th of February, being one of the four above mentioned. I paid on the return journey:—

For the basket of Cochins	s. d.
For the Sebrights	2 10
For the Game Bantams	3 6
For the other Game Bantams	1 6
	0 0
	7 10
I am now asked to pay	3 6
	11 4

Compare the charge to Rochdale—viz., 6s., with the charge back, 11s. 4d.; note that all but the basket of Cochins were within a few ounces of the same weight; add also 1s. 6d. telegram to Rochdale, to know why my birds were delayed; besides, damage to the birds in a delay of one day whilst confined in their baskets, the attendance of my man at nearly every train to meet the expected birds, and correspondence with the Secretary of the Rochdale Show, and I think I have just ground for asking an alteration of railway charges and arrangements in the matters of poultry carriage. I do not mean to pay the amount claimed; but I shall refer the claimants to the railway authorities at Rochdale, who may, if they like, try whether they have a remedy in the County Court against me.—GEORGE MANNING, Chapel House, Springfield, Essex.

PROFITABLE DUCK-BREEDING.

I VENTURE to offer a few words upon the rearing and management of Ducks—those general favourites in the farmyard and of the cottager. The Duck in particular is the country housewife's bird. Its hardiness renders it independent of that care which other fowls require, and it is one of the very best scrap-savants or scavengers. Potatoes and vegetables of all kinds well cooked, with a little sharps or pollard, constitute good food for the Duck, which swallows whatever you give to it in the shape of food, not refusing young frogs, toads, and garbage of all kinds, and that with a relish which is truly pleasing to witness. My favourites for years have been the Aylesbury and the Rouen; but during the last two years I have bred from a cross between the White Call Duck and the Aylesbury drake. The birds so produced are not quite so large as the Aylesbury, but they are much the hardier of the two, lay more eggs, and are better sitters and foragers. At five months old I have had them weighing from 5 to 5½ lbs. The produce from six Ducks the last two years was—Eggs, 932; young Ducks hatched, 281. In 1864:—Eggs laid, 260; eggs used for sitting, 137; young Ducks hatched, 131. In 1865:—Eggs laid, 672; eggs used for sitting, 202; young Ducks hatched, 146; and the market value by August was for all fit for sale, 5s. per pair. The eggs, when I have any for sale, are 3s. 6d. for fifteen. Your readers will no doubt remark the great difference in the number of eggs in 1864 and 1865. In 1864 the Ducks had their own way, and laid where they liked; but in 1865 they were deprived of their usual laying-places, in a way beyond my ability to remedy.

Profitable Duck-breeding depends a good deal upon the situation and convenience of a farmyard. That at this place is in every way excellent for Ducks, being close to a fine pond of water fed by springs from the hills in rear of the farm buildings, and there is a small paddock also. The land, pond of water, and paddock, are altogether about an acre in extent, and fenced in on all sides. The soil is a strong, heavy, wet, brown loam, near a close and adhesive calcareous clay; the formation oolitic, and presenting great varieties of soil in the neighbourhood; and the aspect, south and east. The poultry-house is built of bricks, and the roof is of red tiles.

About the middle of March we commence sitting hens upon the Ducks' eggs, to have ducklings for green peas in June. If three or four hens wish to sit within a day or so, about eleven eggs to one hen are sufficient; if a good old sitter and mother, thirteen are allowed. By the time these eggs are hatched we manage, if possible, to have six or eight more hens sitting upon Ducks' eggs. Should four hens bring out thirty or forty ducklings, two hens take charge of and nurse them. I have had five hens hatch fifty-two Ducks, have put them to two excellent mothers, and have not lost one while they had charge of them in the coops. As soon as the ducklings are what we term nest-ripe—sprightly, strong, and hungry, they are put under coops with the mothers out of doors, and between the coops is placed a feeder for the ducklings to feed under. One of an oblong form is best. Mine, for Ducks, is about 8 feet long by 1 foot wide, and is made of dry elm boards 1½ inch thick. Its depth is 8 inches by 4, and in it are cut pigeon-holes—viz., one at each end and one in each side, to allow of the Ducks going in and out to feed. The top is covered with galvanised wire-netting, with one-inch meshes, to prevent small birds, &c., devouring the food. We commence feeding with chicken rice boiled in-skimmed milk for the first six weeks, both for chickens, Ducks, and Turkeys.—J. D.

PREVENTING SWARMING

I AM absent from home during the day, and find it impossible to take runaway swarms, and am a little nervous at changing bars from one hive to another for the purpose of multiplying swarms. Do you think if I were to make a small, long passage from one bar-nive to another that the bees would enter the empty hive, fill it with comb, guide-comb being previously attached, and breed a new queen therein? I should close the entrance to the empty hive until I thought it pretty full, then open the entrance at front, and close the connecting passage, so as to leave them to their own resources. SMOKE TOWN.

[It is very unlikely that bees would take possession of a second hive far detached from the parent stock, and with such restricted communication. Even if they were to do so they would not raise a young queen therein, as you suppose, but would remain one family under the original sovereign. If

young queens were bred it would probably be in the old hive, and the result would be the issue of one or more swarms in the ordinary way.

The bee you enclosed looks rather dark for a Ligurian, but the point cannot be decided without an actual examination of the stock itself. No reliable opinion can be formed merely from the inspection of dead bees.]

REMOVING STOCKS

I HAVE had a new bee-house made, and wish to move the hives I now have into it from their stands. How am I to lift the hives off as I conclude they would adhere to the wood? and will not the bees come out at the bottom? Would it be safe to move them now, or better to wait till they swarm in the summer? The distance to the new house from their present abode is about 20 yards.—A. F. S.

You will find no difficulty in merely removing your stocks, if, after previously loosening the hives from their floor-boards (we imagine these latter to be fixtures, or they should accompany the hives), one day you lift them quietly, and towards the evening of the next, convey them to their new position. So many bees will, however, return to their old place from such a short distance as 20 yards, that we should advise the old stocks being left where they are, appropriating the new bee-house to the reception of swarms.]

OUR LETTER BOX.

SPANISH PULLET (*Percy Cross*).—Nearly three weeks having elapsed you may now conclude that her progeny would be pure. You will see some notes on the management of Ducks in our present Number. In "The Poultry-keeper's Manual," published at our office, are coloured and other drawings of various kinds, as well as directions for managing them.

PAISLEY SNOW (*Fair Play*).—All that you say may be quite true, but so great a length of time having elapsed, and as we have declined to insert defensive statements, we must not revive the complaints.

INCUBATOR (*J. T.*).—The temperature is 10° too low, it ought to range from 100 to 105°.

TESTING EGGS (*E. A. P.*).—They may be put into water not hotter than 100° with perfect safety.

UNFERTILE EGGS.—INCUBATOR (*Captain*).—After eggs have been under the hen for a week, those which are unfertile may be detected. A description and drawing of the mode of detection are in the "Poultry-keeper's Manual," published at our office, price 7s. 6d. As the incubator you mention failed, but we do not think it can have been properly managed, try Brindley's. His direction is St. Alkmund's, Derby.

FOOD FOR ZEBRA PARROQUETS (*J. Worthington*).—Chopped egg, bruised hemp sopped with crumb of bread, and started rape, are good food for Zebra Parroquets.

BRAHMA FOOTBARS (*Idem*).—The origin of the Brahmas is a vexed question. The general opinion is that the Dark is the true bird. If they were the result of a cross between a Dorking and the Light they would throw clean legs, five claws, and all the different shades that come in Dorking breeding. The best and largest breeders of the Pencilled variety can prove they never breed a faulty bird either as regards clean legs, five claws, Light or Dorking birds. All crosses will throw back at times, it is an inevitable result.—B.

FOOD FOR GOSSINGS (*Idem*).—Meal mixed in water, and put in a vessel that has a growing sod of grass at the bottom, is the best food for Goslings.

CRUSHED OATS AND BARLEY (*E. C. K.*).—They are merely crushed flat, the outer skin being thus broken facilitates digestion. In the best conducted stables there is a machine for the purpose. It is formed of two cylinders, with just space enough to have the grain crushed as it passes between them. Horses supplied with oats so crushed are kept in as good condition with one feed less daily as horses fed with oats uncrushed.

DISTINGUISHING A COCK FROM A HEN PIGEON (*Inquisitive*).—The cock is bolder, more prone to fight, coos louder, is thicker about the base of the beak and neck. In playing he turns round and round, which the hen rarely does. The hen when cooed to twinkles her eyes, seems to swallow, raises the shoulders of her wings, and cartseys to the cock. Two cocks, also two hens, will occasionally pair, and go through all the actions of a pair as far as possible; but two cocks will also coo after other Pigeons. Two hens will lay four eggs. Lastly, in billing, the hen puts her bill in the cock's. Thus, two cocks will both open their mouths; two hens will both try to put their beaks in that of the other. Perhaps your correspondent may tell by these signs what sex his Fairfairs are. I do not know of better food than old tares and small beans; a little buckwheat barley, or canary seed for a change.—B. P. BERN.

POULTRY MARKET—MARCH 26.

THE tendency of prices is still to rise quite as much as they generally do at this time of year.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 56.4°; and its night temperature 36.2°. The greatest heat was 79°, on the 7th, 1859; and the lowest cold 21°, on the 6th, 1851. The greatest fall of rain was 1.19 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

MELON AND CUCUMBER CULTURE.

THE cultivation of the Melon has been so well treated of in a series of papers by Mr. Abbey, that I can have but very little to add, as mine and his ideas on the subject are so much alike.

I am obliged to "AN OLD SUBSCRIBER," for the compliment he has paid me, although he is wrong in assuming that I once lived at Cricket Park. He is correct, nevertheless, in stating that Mr. Davies grows Melons and Cucumbers well, and, indeed, everything else he takes in hand is well done. I may here state, that I attribute a great portion of my success to the kind encouragement which Mr. Davies gave me when a boy. At a very early age the love of flowers had taken strong hold of me; I thought nothing of walking ten or twenty miles if I could procure cuttings, or plants, of any good flowers.

The lessons I learnt when chance gave me an opportunity of visiting the beautiful gardens at Cricket Park, in my early boyhood, have been always fruitful of good results, and are so deeply engraven on my mind, that they have ever since formed prominent landmarks in my memory and models for my guidance; and if I had a son who wished to be a gardener, Mr. Davies is the man, and Cricket Park is the place, above all others, I should like to send him to.

But to return to the subject which forms the heading of my present paper, I will, as it has been requested, give a few plain hints on the cultivation of the Melon in houses heated by hot water, referring "AN OLD SUBSCRIBER" for general details to Mr. Abbey's articles on the cultivation of the Melon.

Where it is necessary to have a moderately early crop of Melons, no time should be lost in sowing the seeds. I generally sow about five or six seeds in a large 60-sized pot. As soon as the seeds are up the plants should be carefully separated, taking care to preserve their roots from injury; they should then be potted singly into large 60 or 48-sized pots in any good soil, and placed in a temperature of 70° or 75°, in a position as near the glass as possible. A bottom heat of 70° will be sufficient to cause the seeds to vegetate. As soon as the plants have well filled the pots with roots, they should be shifted into 16 or 24-sized pots, and a stick put to every plant to prevent its suffering injury. The bed in which the Melon plants are to be planted out may in the meantime be prepared.

The house in which the Melons are to be grown should have an ample quantity of pipes in it, so that the desired temperature may be obtained without the necessity of ever making them very hot. Where the heating surface is in-

sufficient, there red spider and thrips will be sure to appear and when once these insects obtain a hold, there is very great difficulty in extirpating them without sacrificing the crop. The pipes should also be distributed as equally as possible over the house.

The bed in which the Melons are grown should be about 4 or 5 feet from the glass, and a wire or wood trellis should be fixed about 18 inches from the glass to train the vines on. If the bed in which the Melons are to be grown is 5 feet wide, there should be two four-inch pipes in the bottom for bottom heat; but if only 2 feet wide, one pipe will be sufficient. There should be about 1 foot of broken bricks placed above the pipes for the purpose of distributing the heat regularly all over the bottom of the bed, and on these should be placed a layer of charcoal broken rather small, with the small dust sifted out of it, to keep the soil from passing down amongst the drainage. The soil, which should be about 2 feet deep, may then be put in in layers and made moderately firm. A good stiff loam, without manure of any kind, should be used for Melons. It is a good plan to put in some drain-pipes at intervals along the bed for the purpose of pouring down water amongst the drainage in order to produce a moist bottom heat.

As soon as the soil of the bed has become well warmed through, and the plants have nicely filled their pots with roots after the second shift, they should be planted out, and to each plant a nice straight stick should be put, reaching from the bed to the trellis. The plants should not be stopped, but ought to have all the encouragement that can be given them in respect to heat and moisture, to cause them to reach the trellis as quickly as possible. They must also have all the air that can be given on all favourable occasions. The night temperature most suitable for them during their season of rapid growth—that is, before they begin to show fruit, should never be lower than 65°, and the day temperature should average about 75° or 80°.

None of the leaves should be touched till after the plants have reached the trellis and been stopped. As the plant makes fresh leaves above the trellis, those on the stem may be gradually taken off, beginning at the bottom. In doing this care must be taken not to cut the leaf off close to the stem; it is better to pinch the leaf off by degrees, and allow the stalk of the leaf to wither-up and fall off of its own accord. I like a clear stem of about 4 or 5 feet long, as I find such plants are not so liable to go off at the collar as when the vine is nearer the ground. As the vine grows it should be stopped at every second or third joint; and as soon as the plants are in flower, choose an opportunity when the atmosphere of the house is pretty dry, to fertilise with the pollen of the male blossoms. The best time to do this successfully is in the morning after there has been sufficient sun to dry the flowers after syringing, and the house should be as free from moisture as possible for an hour or so after the young fruit have been set.

As soon as a sufficient quantity of fruit is set on each plant and they begin to swell-off freely, the plant should be liberally supplied with guano water in a clear state

three or four times a-week, until within ten days or so of the fruit's ripening, when all water should be withheld, the temperature of the house increased, and abundance of air given. This will impart the necessary flavour to the fruit. When the fruit are fairly set and are swelling off, all the fresh shoots made by the vine should be pinched out, so that the whole of the energy of the plant may be concentrated on the fruit. All the first and principal leaves made by the plant must be preserved in a healthy state as long as possible, as these are the chief lungs of the plant by which it receives its atmospheric food. To guard against green fly and thrips, the house should be well fumigated two or three times during the free growth of the plants; the syringe, too, should be freely used before and after the fruit is properly set, but in order to prevent scorching syringing should be done pretty early in the morning, so that the foliage may be dry before the sun shine very strongly on the house, and in the afternoon the house should be shut up, and the plants syringed, as soon as the vertical rays of the sun are off the glass.

The Cucumber requires similar treatment to that recorded above for the Melon, with the exception of the drying-off process, and the difference in the soil, which cannot be too rich for the Cucumber. It will also do with a higher and more humid temperature than the Melon, and this temperature must be continued till the fruit be fit to cut. To be successful in setting the young fruit of the Cucumber during the winter months, care must be taken in choosing an opportunity when the pollen is quite dry. Fertilisation is best done with a small brush, as the fruit is often injured by pressing the male blossom on it too hard. A plan of a new range of Melon, Cucumber, and propagating houses, &c., will shortly be given, showing the positions the plants occupy.—J. WILLS.

CULTURE OF VINES IN POTS.

(Continued from page 245.)

WHERE the convenience of a house with a suitable temperature, and means for plunging the pots in bottom heat is not at command, it will answer nearly as well to plunge the pots in Cucumber or other hotbed-frames; the temperature of the bed being 75°, and that of the atmosphere 65° by night. In this the pots are to remain until the eyes have started, and have grown so as to fill the pots with roots. By this time another hotbed will most likely be in readiness for successional crops of Cucumbers or Melons. Soil in which to pot the Vines should be brought into the frame to become warmed, which it must be, forty-eight hours before they are potted. The Vines, being potted in six-inch pots, should be plunged in the bed again if the heat is sufficient and can be kept up by linings, or they may be transferred to another and new bed, choosing a warm calm day for the operation of potting or transferring the canes, so that they may not receive a check. Here they may remain until they can be removed into a house with a temperature of not less than 60° at night. The house may be a vinery at work or any similar house. Previously to removing the Vines from the frame, the pots should be gradually withdrawn from the hotbed, so that when removed to the house they may not receive a severe check, as they would were they removed direct from the hotbed and placed at once on a cool bottom. In the house the Vines are not to have an inferior situation, but the best the structure affords, and that must be light, and not very airy at this early season. If there is a pit filled with fermenting materials plunge the pots therein to the rim, and when they become full of roots shift the Vines into nine-inch pots, and ultimately into 11-inch or larger pots, after which they are to have a position near the glass. The canes raised in this manner will be of the thickness of the little finger by autumn if at all liberally encouraged, and the wood will be brown and hard if they have had the benefit of all the light possible, by being 1 foot from the glass of an unshaded roof, and had a sufficiency of heat with abundance of air. Many of them will fruit in the following year, but will not be eligible for very early forcing.

Where there is not the convenience of a vinery that is started in January or February, so as to have by the time the eyes are removed from the hotbed (where they were placed in January or February), a temperature of from 60° to 65° at night, and the means are limited to a greenhouse or other cool house, the eyes may be inserted in the beginning of February, and be plunged in a hotbed such as is used for raising annuals, and in this they may remain until April, when they may be removed to

the warmest and least airy part of the house. If there is no hotbed at command in February, they may be inserted in March, and plunged in a mild hotbed; they then grow rapidly, and, when the bed becomes cold, may be removed to the cold house, giving them a light and airy situation. Pot the young Vines in six-inch pots in April or May, and by June they will have filled these with roots, when they may be transferred into nine-inch pots, training the canes as they grow, to the roof if possible, and watering when the pots become full of roots with liquid manure at every alternate watering up to September. The use of liquid manure should then be discontinued, and only half the quantity of that previously given should be afforded, gradually reducing the supply so as to leave off watering altogether when the wood becomes brown and the leaves turn yellow. Let the canes grow as they like, and without heading the laterals. By autumn the result will be strong canes, considering the means, but of no value for fruiting in the succeeding year, though they will do for planting out in the following spring in borders; but, if this is contemplated, cut in the laterals in September, which will admit more light to the leaves and cane, and cause the latter to ripen more fully.

Where there is not the convenience of a hotbed, the eyes may be made and inserted in pots in February or March, and be placed on a shelf in the warmest part of the greenhouse; the soil being kept moist, the eyes will commence growth when a minimum of 50° of temperature is reached. The soil must not be kept wet, otherwise the eyes will rot, and if kept dry they will not grow. When the Vines have grown so as to fill the pots with roots, shift into six-inch pots, and if by July they have grown sufficiently to fill these with roots, give nine-inch pots, and, under liberal treatment, they will merit the name of Vines by autumn.

Raised by any of the above means, the canes after the leaves fall may be kept in any place free from frost, though it is not absolutely necessary to exclude it; only, if no fire heat is used to keep out frost, the pots must be protected by a covering of dry hay or litter so as to preserve the roots from injury. The temperature when the Vines are at rest should not exceed 45° from fire heat. The soil in the pots should not become so dry as to cause the wood to shrivel; a little water should be given if necessary to prevent this. The canes intended for fruiting should, immediately after the leaves are off, be cut in to the length required, and those not strong enough for fruiting should be cut in to two or three eyes. The parts cut off may be kept until required for taking eyes from, with their lower ends in moist soil.

The Vines not sufficiently strong for fruiting in the following year being cut in to two or three eyes, may have the soil shaken from the roots and be repotted in nine-inch pots. Spread out the roots as much as possible, and work the soil in between them. This should not be done later than the middle of February, even for the Vines that are to be grown in cool houses, for though they may not grow they will, nevertheless, make roots.

If from these Vines ripe Grapes are desired on New Year's-day, select some of the strongest of such as had the wood ripe early in the season; those from eyes put in in January and grown throughout in a strong heat, having the wood ripe in August, are the best, and they cannot be too strong. Cut them in to two eyes early in October, turn them out of the pots, shake the soil from the roots, pot them in nine-inch pots, and keep them in a cool house until November. They may then be placed in a house having a temperature of 50°, plunging the pots in a hotbed of 75°, half their depth at first, and then to the rim in a fortnight afterwards; increase the temperature 5° every fortnight, and when a heat of 60° by night is attained, that degree is not to be exceeded until the 1st of February, when an increase of 5° more is necessary. When the nine-inch pots are full of fibres, pot the Vines in 12-inch pots; these will be filled with roots by February, and a shift into 18-inch pots will then be necessary. The canes, from the first, are to be trained to the roof or rafters, and the laterals are to be stopped at the first leaf; but after the final shift allow the laterals to grow, keeping those at the upper part of the cane closely stopped to one joint—that is to say, when the lateral has been stopped at one joint and it has grown again, stop that growth at the first leaf. The cane should be stopped, or have its point taken off, when it has attained the length of 9 feet, and the laterals for 3 feet beneath it are to be stopped to one joint as fast as growth is made.

By May the canes will be strong, and the wood turning

brown. Now reduce the laterals gradually, diminish the supply of water, and give more air and a temperature of 60° by night, and from 85° to 90° by day with sun, and 75° without it, and the wood will soon become of the colour of amber, and be as brittle as glass. Early in June place the Vines with the pots on their sides close to a south wall, and on Midsummer-day strip off the foliage, then prune them. After pruning set the pots upright on boards, and not on their sides, and after allowing them to remain thus for six weeks, they may be placed in a house with a temperature of 60° at night, and which is kept very moist and rather close; they will soon break freely, showing fruit from almost every eye. Now, these Vines, or others of this description, if kept in the house until midsummer, will have the wood even better ripened, and if then placed at the foot of a south wall will go to rest, and be fit for forcing so as to have fruit ripe in March, which is much more difficult to obtain than in January; for almost any strong Vine, if well furnished with sound, plump eyes by the end of June or July, if it then receive a sudden check from the leaves and laterals being taken off suddenly, will start most of the principal eyes, and the shoots from these will mostly show fruit at the fifth joint, which, under favourable conditions of heat and moisture, will ripen at a late period of the year.

Another batch of the non-fruiting canes being placed in heat and grown or in a house having a temperature of 50° at night to begin with, and an increase of 5° fortnightly up to 65°, will, with the treatment before-named—viz., shifting into 12-inch pots when the pots become full of roots, and into 15 or 18-inch pots in April if started in January, or in May if started in February, have strong and well-ripened canes by August in the one case, and by September in the other. The first are calculated to ripen with greater certainty a crop of fruit in April and May, and the second in May and June, than these raised from eyes in the same months as the above were started.

The Vines that were raised in a greenhouse in the previous year are to be shaken out and placed in nine-inch pots by the middle of February, or not later than the beginning of March. These, with the soil kept moist, will shoot strongly at the end of March, and are to be trained to the roof of the house at 1 foot from the glass. The first laterals should be stopped at the first leaf, and this continuously until the point of the shoot is taken out at the height of 7 or 9 feet; and the uppermost laterals for a distance of 3 feet or so downwards are to be closely stopped to one leaf at every succeeding growth. The laterals situated lower down should be allowed to grow if they will. In June give the Vines their final shift into 12, 15, or 18-inch pots, according to their strength. Syringe them in the evening, and never allow them to suffer from want of water, and give liquid manure at every alternate watering in July and August. Under these conditions, and with a moist atmosphere, they will make strong canes by September, when they are, after the last week, to have no more water than is sufficient to keep the leaves from flagging, and the laterals are to be reduced by degrees, and finally cut off close to the cane in the beginning of October. These Vines will mostly bear fruit in the following season.

If bushes are desired the cane is to have a strong stake placed by it in the pot, 3 feet long for two-foot bushes, and longer for those of greater height; three-foot bushes are, in my opinion, high enough. The stake must be 1 foot in the soil, and if it be charred a little it will neither be so apt to rot, nor will fungus be so likely to attack it, as would otherwise be the case. To this stake the cane is to be loosely tied, and when it has grown to the top of the stick take out the point. The laterals will then break strongly; stop them at the first joint or leaf, and pick out the eyes from the canes for a distance of 6 inches from the soil. Above this point will be seven or eight leaves, with eyes in their axils, and laterals coming from the sides of them. Pinch in the three uppermost laterals to one leaf as they are made, and let those below grow and hang at freedom. In June give the Vines 11-inch pots, and throughout their growth keep them near the glass. The laterals are to be removed in September by degrees, and take care to give no water beyond that needed to keep the leaves from flagging. These canes will fruit another year, but are not so good nor certain as canes cut-in to eight joints, not counting the three lowest, which are mostly embryo eyes, which ought to be picked out with the point of a knife. This should be done immediately after the leaves have fallen.

We have now, 1st, Strong canes raised in January and by September fit for forcing to produce fruit in the following April and May. 2nd, Canes raised from eyes in February, and by

October ripe enough and strong enough to afford fruit in July; or if started later, in August and September. 3rd, Canes two years old for fruiting in January and February. 4th, Two-year-old canes for fruiting in March. 5th, Canes one and two years old for fruiting in September, the fruit hanging up to Christmas, or March if needed; and, 6th, Vines for bushes for cool-house culture in pots. All these I will notice in future articles.—G. ABBEY.

MORE GOSSIP ABOUT ROSE-GROWING.

I AM much obliged to your correspondent Mr. A. H. Kent for his reply to my communication in your Number of December 26th, on the subject of using the Manetti stock as a means of getting Roses on their own roots. I have derived some valuable hints from that reply; and if it will not be trespassing on his kindness, or that of some other of your correspondents, I shall be very glad to have farther information on one or two points alluded to therein.

First, as I shall, of course, be very glad to arrive at the knowledge of the form of Rose-growing likely to be best suited to my soil, through the speedier process of benefiting by the experience of others rather than by the more tedious one of proving this by my own experiments, I herewith send what I call a popular description of the nature of the soil of my garden, premising that I do not possess such a knowledge of agricultural chemistry as to enable me to give a scientifically or chemically correct description. The soil of my garden is heavy, but inclined to be boggy or dark in colour, rather than clayey or red. It is shallow, not being more than from 2½ to 3 feet deep, and at that depth rests upon a particularly bad subsoil, consisting of clay and gravel, the water running from which leaves a peculiarly rusty-looking deposit. When from any cause the greater part of the roots of any of our fruit trees find their way down into this subsoil, the tree speedily dies, the decay apparently beginning at the extremities of the youngest and thinnest branches. These die away in lengths of from 6 to 12 inches in a single season, and in two or three seasons lead to the death of the tree altogether. I find I can grow Broccoli and Cauliflowers, and indeed the whole Cabbage tribe to perfection, but have hitherto failed to grow good Carrots, for which I expect my soil is too rich and heavy. I imagine, also, that it will prove too good for the Manetti, unless I can reduce its over-luxuriance as a stock by annual removal or root-pruning. I fancied last year that my plants made too much wood, and produced much fewer blossoms that they ought to have done; but as the ground was a virgin soil to Roses and liberally manured, this tendency may be corrected after two or three years' growth in the same situation. When I describe it as a virgin soil to Roses, I mean that other plants—those for bedding-out, for instance—had been grown upon that part now occupied by my Roses, but not Roses. It was carefully and fully drained about four years since.

As some proof of the character of my soil as to richness, I may state that some of the free-growing Hybrid China and Bourbon Roses, as Blairii No. 2, Charles Lawson, &c., have made shoots of 6 and 8 feet long in the first season after budding—that is, they were budded in the end of August or the beginning of September, 1864, and made this growth during the following year. Mr. Kent speaks of "well-budded Manetti plants in nine cases out of ten making strong shoots the first year," and again that "if budded early in the season a plant is formed at once, which may be removed in the autumn." Would he kindly say how early he thinks might be desirable to bud the Manetti in this neighbourhood (Shropshire)? I have hitherto budded in the last week of August or first week in September.

I also owe many thanks to your well-known correspondent, the Rev. W. F. Ralelyffe, for his remarks in No. 250 on my communication about Roses published in your Journal of December 26th; and I am sure that he, or Mr. Kent, or both, would confer an obligation on many of your readers if they would give some plain and precise directions as to the propagation and budding of the Manetti. I do not know how it has been with others, but I have found some difficulty this year in procuring Manetti stocks. One of our principal growers, of whom I ordered six dozen, supplied me with two dozen, with an apology that the demand was so great, that he was himself a buyer instead of having any to sell. Therefore it is desirable, if not necessary, for amateurs to be able to propagate the Manetti stock themselves if they wish to experimentalise with it to any extent.

In the autumn of 1861 I put in about a hundred Manetti cuttings in a west border under a wall in the early part of September, and they seemed all to do well until they began to grow in the spring, and then all died with the exception of about twenty. This autumn I put in about the same number under a north wall, and about ten per cent. of these have rotted already, owing, I am sure, to a superabundance of moisture at the roots. I have also about fifty more cuttings in the west border before alluded to, protected by a frame, and which so far seem to be doing well. My experience thus far goes to show that it is not so easy to strike the Manetti as some people represent.

Then as to budding the Manetti. The plan that seems to answer best on my soil is to plant shallow, and earth up the stocks about 3 or 4 inches, much in the same way that you would earth up a row of Cabbage; and when you come to bud, this ridge of soil must be opened, and the bud inserted 2 or 3 inches above the roots. I have found the success of budding on the Manetti to depend very much upon there being three or four fine days immediately after budding. When the budding has been followed by wet, especially if continuing for two or three days, I have found many buds fail through the wet penetrating to the junction of the bud with the stock, and so causing the bud to rot. This is especially the case if, in opening the trench with either trowel or spade, in order to bud the stock, simply a sort of basin-shaped hollow is made instead of the ridge being thoroughly levelled to fully an inch below where the bud is inserted. In such instance, in the case of rain the tying of the bud is kept constantly wet, and the bud is almost sure to rot; therefore every precaution should be taken to preserve the bud and its surroundings, for some days at least after insertion, in a state of comparative dryness, and to bud when there seems to be the greatest probability of settled fine weather.

There is a point connected with this part of the question upon which I should be glad of the opinion of your correspondents before alluded to, and that is when this ridge of soil should be replaced about the Manetti—in the case of early budding, probably in a month or six weeks' time, or as soon as the bud has made about 4 inches of growth; and in the case of light soils I should say always before the winter, as I cannot help thinking the soil would prove a great protection to the newly inserted bud. In heavy soils like mine, I am inclined to think that the earthing-up of the budded Manetti before spring, would be likely to lead to the rotting of any buds that had not formed a perfect junction with the stock.

I have thus contributed my mite of information on this subject, and shall be glad if the propagation and budding of the Manetti can be thoroughly ventilated in your next two or three Numbers. I have for some time been convinced that when rightly used, and for soils for which it is adapted, it is by far the best means of growing Roses. If it has a fault it seems to be its excessive luxuriance, which in heavy rich soils causes the Roses budded upon it to make too much wood; but this may, I suppose, be corrected by an annual removal or root-pruning. I have had no experience as yet of its use in growing Roses in pots, though I have seen it recommended as the best stock that can be used for that purpose.—COUNTRY CURATE.

In reply to "Locu Ness," I beg to state that I live in Essex, about twenty miles east of London, and the soil in which my Roses are grown is a tolerably light one, resting on a sort of gravelly clay. I have from twelve to twenty plants of all the leading kinds (about 1800 plants in all), and so am able to form a pretty good opinion of what a Rose is after having it a season or two. I must confess that I did not pass judgment on King's Aere so much from the blooms which my plant bore as from those which the raiser of this Rose exhibited at the Crystal Palace Show. I concluded that if this gentleman could only show about one good bloom in some two dozen specimens, it was at least not at all a constant flower.

Perhaps "Locu Ness" lives in a moister climate than this. Last summer was a very trying one for Roses in this part of Great Britain, it was so hot and dry. Should the coming summer be more favourable than the last, King's Aere may prove a better flower than I at present take it to be. I sincerely hope it may, for it seems to be a Rose of good constitution, and is, moreover, an English-raised flower.

I forget whether "Locu Ness" mentioned Olivier Delhomme. If he has not yet obtained that variety, I can confidently recom-

mend it as a first-class flower of very fair habit. I think, too, that if he has not Madame Clemence Joigneaux he would be pleased with that flower.—P.

VERBENAS

OUR HANGING BAY

YES, we had a grand battue of new and old varieties at Shobden Lodge one day last autumn; and if we killed a good many it was not to fill our bags with them, but the dungheap, while those that were spared were for the stocking of the preserves again. We make, by-the-by, a great outcry about French Roses, the numbers that are brought out, and the few that are kept afterwards; and yet may not our French friends cry out in return and say we give them a Roland for an Oliver? Nay, do they not? Pathetic have been the complaints that I have heard from Messrs. T. & K., Mons. R. C., and others. "Ah, sir! I buy every year your new Dahlias, Geraniums, and Verbenas; but there is very little difference from one year to another, and I shall give up buying any at all." Now, my wonder is, that they buy any of these novelties, considering how few are the amateurs in France. My object, however, in mentioning it is to show that the complaints are not all on our side. Are they groundless on theirs? Every year we have a multitude of new Verbenas, and I am constrained to say that a very large proportion of them do not come up to the standard they claim to have reached. Let it be borne in mind that there are two distinct objects for which the Verbena is raised—for bedding-purposes and for exhibition. Would it not, then, be only fair that that for which a new variety is useful should be fairly and distinctly stated? for while many a bedding variety would be useful in a stand, many of the pot or exhibition varieties are useless for a bed. Why is it that Purple King is still the best bedding Verbena out? It is neither the size of the pip nor the brilliancy of its colour, but its habit of growth, the profuseness of its bloom, and the uniformity of its colour. There is no white or coloured eye, but it presents one mass of purple to the spectator; and while other varieties more or less eyed are used, undoubtedly, for bedding, yet the nearer the approach that could be made to it the greater would be the acquisition for such purposes. To have the habit of Purple King is the standard which each raiser claims to have reached. How many have yet done so? The lists will answer this. Instead of giving the lists of the new varieties of last season, I shall give the list which we selected of those to be retained, adding a few observations on some of them at the end.

1 Admiral Mitford	20 Waverley (Banks)	40 Nobile Carolina
2 Annie (Cooling)	21 Madame Lefevre	41 Franzini
3 Chieftain	22 Faust	42 Garibaldi
4 Purple Emperor	23 Lord Raglan	43 Grande Duchesse
5 Elie Deans	24 Brillant de Vaise	44 Fantastic
6 Lord Leigh	25 St. Marguerite	45 Admiral Dundas
7 Lord Clifden	26 Nemesis	46 Reines Amazones
8 Foxhunter	27 Grouse des Batailles	47 Merry Maid
9 Princess of Wales	28 L'Ascent de Ballent	48 Gloire de St. Louis
10 Ruby	29 Madame Matras	49 Velvet Gem
11 Grande Boule de Neige	30 Striata Perfecta	50 Emblem
12 Snowflake	31 Le Bon Nicola	51 Glowworm
13 Mrs. Holford	32 Mrs. Elphinstone	52 Princess of Wales
14 Defiance	33 Leon Manser	53 Lilac King
15 Ariosto Improved	34 Quelli	54 Beatrice
16 Warrior	35 Desdemona	55 Purple Queen
17 Ruby King	36 Great Eastern	56 Ne Plus Ultra
18 Beauty (Banks)	37 Vicomte de Balliere	57 Paul Dupont
19 Urban	38 Purple King	58 Dr. Prony
	39 Marquise Pallavicini	

It will be seen that this list comprises many of the very old varieties, such as No. 13, 15, 24, 25, 27, and comparatively few of those of last season, 2, 49, 50, 51, 52, 54, being the chief; but there are one or two things to be considered. It was a very difficult season to judge of Verbenas, the intensely hot weather in the earlier part of the year interfering very much with their growth, and, in many instances sweeping away whole beds, as was the case in the ground of my friend Mr. Banks, and then they did not afterwards recover sufficiently to afford a fair trial. No. 2 is decidedly a striped flower; but there is a washiness about it that makes it very difficult to show even in a stand, unless you can manage to keep it entirely away from the scarlets, &c. 46 is a good flower, in the style of Lord Raglan. 52 is a magnificent lilac flower. 6, 7, 8, are so like one another, that it would be almost impossible to discern the difference between them in a stand, and yet one hardly likes to discard any of them.

As I am frequently asked to give lists of Verbenas, especially

those suitable for small gardens, it may, perhaps, save some trouble if I say that I consider the best *Verbenas*, taking in all their points, to be Admiral Mitford, Lord Clifden, Snowflake, Warrior, Ruby King, Beauty, Faust, Lord Raglan, Nemesis, L'Avenir de Ballent, Mrs. Elphinstone, Grande Duchesse, Fantastic, Admiral Dundas, Géant des Batailles, Merry Maid, Lilac King, and Purple Queen.—D., Deal.

P.S.—On referring to Henderson's list I find that in it are retained about 80 varieties, and in Turner's about 100.

VINE CULTIVATION.

CAN Mr. Thomson or any other Vine cultivator give his experience in the following mode of cultivation?—Instead of planting the Vines at 4 feet apart, plant them at 2 feet, and fruit every alternate Vine once in two years. What would be the effect in quality and quantity, the plants being under glass and each having the same advantages? The finest crop of Grapes I ever had was by inducing the root-fibres to come to the surface by top-dressing with well-rotted dung and leaf mould. I have seen very fine crops of Grapes grown by digging a trench inside the house and filling it with fresh leaves every year. This continued feeding seemed to answer remarkably well, and it was very instructive to watch the roots passing into every part of the leaf mould, which became rapidly exhausted.—CONSTANT READER.

TRANSPLANTING LARGE TREES.

THE following mode of transplanting trees of large size has proved very successful here for some years past. The trees are never lifted, so that the ball of earth is seldom broken. No rollers or wheels are required. Mr. W. Thomas, the landscape gardener, was the first person who introduced the plan here. The apparatus, consisting of a stout plate of iron, say 5 feet by 4, with an iron ring near each corner, is all that is necessary. It can be made by any blacksmith at a cost of about £1. This iron plate is introduced under the ball of the tree, which is kept in position by being tied to each of the rings. Two horses are now attached to two of the rings, when the tree can be taken away to any distance. When it has arrived at the required spot it is untied, and the iron plate is withdrawn.

A large number of trees have been moved here this year in the above manner without a ball having been broken. I am acquainted with the various modes of transplanting, and never found any method so simple or efficient as this.—CONSTANT READER.

APPLE SCIONS ON THE POMMIER DE PARADIS STOCK.

To show you that I know as much about the Pommier in question as any of your correspondents that have as yet written upon it, let me say that whilst on a botanical tour in the south of Russia I crossed from the Sea of Azof to Astrachan, and along the shores of the Caspian, over the Caucasus to Teflis, thence to Mingrelia and Batoum in the north of Armenia. I had, therefore, an opportunity of seeing our little friend in all his pride of place in those mighty mountains that stretch from the Black to the Caspian Seas and divide Astrachan from Georgia, Armenia, &c., and whose summits may be said to be capped with eternal snow. There, amidst some of the most sublime scenery in the world, our petit Pommier, or, what I know for it, the *Pyrus malus præcox*, revels and luxuriates, forming jungles of considerable extent, and throwing up its innumerable progeny in thousands around it. It is found at great elevations, reaching almost to the snow line; however, at these altitudes it is a "wee thing;" lower down the mountains, where the Walnut, Chestnut, and Vine grow to mammoth proportions, it attains considerable dimensions.

Your friend of Sawbridgeworth says that "The Pommier de Paradis should be grown in dry light soils." He may have got this out of his quarto edition of Miller, but I do not think it bespeaks much knowledge of the plant under consideration. My experience of it is just the contrary. The tree in its wild habitats luxuriates in dark, deep, rich, boggy soils, where its roots are always in contact with moisture, and in summer especially so, from the melting of the snow above continually running down the mountains, and watering all the vegetation below copiously. I think those who attempt to grow it in "dry warm

soils" will be like the two friends who killed it by the thousand. They may roast the little Pommier, but they will find it difficult to freeze it to death. I have seen it in too many frozen localities to allow me to think that; in fact, were I to trace its geographical distribution from Persia to Astrachan, and from thence northward, I think it would be found a fellow denizen with the Siberian Crab itself. This I know, that both the *Pyrus astrachanica* and *P. præcox* are hardy at Warsaw and Moscow, and the two are found inhabiting the same localities as far south as Persia.

As to Mr. Rivers's supposition that this and the Dwarf Apple of Armenia are the same, I cannot say whether it is correct or not, as I have not seen the article in the "Horticultural Transactions," but I may say that the *Pyrus communis* and *malus* have each of them other representatives in these regions, such as the *Pyrus communis flore pleno*, &c.

Now, to return to the observations of your correspondents about this tree, I may say that no one has killed it but Messrs. Rivers and Pearson, whose importations and killing, to my mind, are wonderfully alike in time, place, and quantity. Mr. Rivers's having such and such a stock has very little to do with establishing or proving the hardness or tenderness of the tree in question. I have also my Nos. 1, 2, &c., of surface-rooting Crabs, but I have not taken forty years to bring them into action. I send you some of them that you may judge of their rooting propensities. No. 1, I call Géant des Batailles. I think you will allow that it is a good specimen of a surface-rooter. No. 2 is also very good, and No. 3, Nain enfant, as dwarf as you could wish to see. I do not find that the surface-rooting stocks possess any of the dwarfing nature of our Pommier; they are each good in their several spheres, the one to grow large trees upon, the other to grow little trees for little gardens, or where several sorts are required in a small space.

Your correspondent Mr. Robson, I think, mistakes the purpose for which Paradise stocks are advocated. He says a less quantity is produced by trees on this stock than by the same number of trees on a free-growing stock. This, I think, admitted by all parties. What we claim for the Paradise is its dwarfing nature and early-bearing character, making it a useful stock for such as have small gardens yet require to have a diversity of fruit. We all know that a tree spreading over 20 or 30 square yards will, possibly, yield more Apples than the twenty or thirty trees on Paradise stocks which will stand on the same space of ground. In the one case you have one sort of Apple to repletion, in the other twenty sorts in moderate abundance. This is all we advocate, and do not deny the contrary proposition; yet to all who want to have large Apples quickly in bearing, we say, Use the Paradise stock. I had a tree here in 1865 that weighed, with roots and branches, half a pound, and this little tree, 18 inches high and no thicker than a little lady's little finger, bore three fruit, one weighing 15 ozs., the other two just over 1 lb. Here was an instance of a tree producing four times its own weight of fruit, and the more I see of the true Pommier de Paradis stock the more I am convinced that it is the stock to graft large Apples upon. Small-growing Apples are generally produced upon small-growing trees, and, therefore, are less needed upon the Paradise stock.

May I ask what Dr. Hogg means, in his "British Pomology," by recommending certain sorts to be worked on the Paradise stock? Is it a fact that he had any other stock in his mind's eye at the time than the said Pommier? If so, I would urge all writers on pomology, when speaking of stocks, to give right names to things. Why give the name of Paradise to the Doucin, or the Dutch creeper, or to any other surface-rooting stock? The Pommier de Paradis seems to have had the priority, and why deprive it of it?

I have now to say that what are called Doucin and English Paradise stocks are nothing more than some surface-rooting Crabs, chosen for their free-rooting propensities by somebody, just as Mr. Rivers and myself have chosen our No. 1's, and which we both mean to make so much of. Some years ago I bought five hundred Doucin stocks from Mr. Rivers, and five hundred from a Woking house. I planted them as follows:—Mr. Rivers's first, and the Woking ones second, with three thousand Crabs following; now I declare and affirm that I never could tell the difference between the trees grafted on any of the three lots; they all grew alike strong, and threw up stems 6 feet high the first year after grafting. So much for the dwarfing character of the said Doucin sent by Mr. Rivers, which, I must say, was quite true to name and description, and the right sort, as far as I am a judge. The Woking stocks

were English Paradise, or at least what I have always seen for it; and both stocks, as already stated, forced on the trees as well as did the Crabs planted in the same quarter and at the same time, and this is the case with every Apple stock I have yet grown excepting the Pommer de Paradis; only that good surface-rooting stocks ripen the wood better than do the deep-rooting kinds, thereby causing the Apples grafted on them to bear sooner. As to Mr. Rivers saying that there are several sorts of stocks used by the French, and called Doucin, I know it to be so, but these stocks are just of the category that Mr. Rivers's and mine are—surface-rooting Crabs.

I have now said my say about the little Pommer, and will leave it for time to prove whether I am right or wrong about its hardness.—JOHN SCOTT, *Merritt, Somerset.*

ORCHARD-HOUSE IN DEVON.

The cultivation of fruit under glass is largely extending in the west of England, and becoming every year a subject of greater interest to amateurs. Several instances of success in this mode of culture may be noted in this part of the country. More particularly would I call attention to the successful management of an orchard-house situated at Billacombe, in the parish of Plymstock, near Plymouth. This house is 60 feet in length by 23 feet, and has a span-roof, the ends of which are north and south, a plan which persons building orchard-houses would do well to adopt, as by this arrangement the early and late sun is secured, a matter of vital importance in the cultivation of fruit under glass. I paid a visit to this house on the 7th of March. Here I found three modes of culture practised—namely, trees planted in borders and trained as half standards; trees planted in borders and trained to wire trellises; trees planted in pots half plunged. Peaches, Nectarines, and Apricots constitute the principal feature; while to Pears, Cherries, and Plums is assigned a limited space. While struck with the neatness, arrangement, and order of the house, the health and beauty of the trees were remarkable, every tree in full bloom constituting a mass of flowers. Several varieties of Peaches and Nectarines could be seen in the differently-formed flowers, which of themselves are an interesting study to every intelligent cultivator of fruit. This house is the property of E. Arkell, Esq., to whom was awarded seven first prizes for pot fruit, at the horticultural exhibition in July last year, in connection with the meeting of the Royal Agricultural Society held at Plymouth.

The mode of treatment Mr. Arkell adopts certainly reflects on him great credit. Giving plenty of air in favourable weather, opening the house early in the morning and syringing the trees, also syringing and closing early in the afternoon, form the principal features of the summer-management of this house. A very large quantity of fruit of the best quality is here produced. The proprietor kindly informed me, that last year he grew in pots Peaches measuring 9½ inches round, while the flavour was very good. This I can verify from having seen some of the fruit.

Another and not the least interesting feature in this house consists in the Vines planted in borders and trained to poles, and not allowed to touch the roof or in any way obstruct the light. Here are about thirty varieties of Grapes, all of which looked remarkably well. These constitute nothing less than a vineyard under glass. There are in addition some hundreds of Strawberry plants in pots in the best state of cultivation. This house is well worth a visit.

The proprietor afterwards conducted me to another glass house. This structure is of smaller dimensions, 30 feet by 18, half span, heated by hot-water pipes, with a hot-water tank in the centre, 12 feet by 4. This house, also, is devoted to the growth of fruit in pots under a high condition of temperature. On the tank I found fourteen Vines in pots, principally Black Hamburgh, and these for health of foliage and promise of good bunches I have never seen excelled. I found Mr. Arkell had left only five bunches on each Vine. This in my opinion is much preferable to a larger number if size of bunch and berry is to be secured. These Grapes were in bloom. In this house I also found several Peaches in pots covered with fruit the size of walnuts, and looking remarkably healthy both in the foliage and fruit. These trees appear to enjoy the temperature suitable for the Vines under the management pursued.

In the same house are also some fine Orange trees in pots, consisting of the Tangierine, Blood, Oval, and St. Michael varieties. Mr. Arkell informed me that the Tangierine Oranges

were delicious. The fruit of this variety was all gathered, while the St. Michael's were covered with fine fruit, which afforded us an opportunity of testing the excellent quality of this fruit, which it has often been said cannot be grown to perfection in this country. Here I found about a hundred pots of Strawberries in a very forward state looking remarkably well. This house, as a whole, was exceedingly clean and healthy, and reflected great credit upon the proprietor, who, as an amateur, has given considerable attention to the growth of fruit under glass, and who has everything carried out under his own directions.—J. SNOW, *Saltram Gardens.*

ROYAL HORTICULTURAL SOCIETY.

The following provincial Floral and Horticultural Societies have been admitted into union with the Royal Horticultural Society:—Alton Floral and Horticultural Society, Boston Floral and Horticultural Society, Bury St. Edmunds Horticultural Society, Darlington Horticultural Society, Devon and Exeter Botanical and Horticultural Society; Durham, Northumberland, and Newcastle-on-Tyne Botanical and Horticultural Society, Faversham Horticultural Society, Fermoy Horticultural Society, Lincoln Horticultural Society, Maidstone Horticultural Society, Manchester Botanical and Horticultural Society, Newbury Horticultural Society, Royal Horticultural Society of Ireland, Shepton Mallet and East Somerset Horticultural Society, Southampton Horticultural Society, South of Scotland Horticultural Society, Staffordshire Floral and Horticultural Society, Swansea and Glamorgan Horticultural and Floral Society, Watford Horticultural Society, and Wrexham Floral and Horticultural Society.

MARCH 31st.—The prizes offered at this meeting were:—1. For the best collection of eighteen bulbs in flower, for which Mr. Young, gardener to R. Barelay, Esq., of Highgate, was first, and Mr. Bartlett, of Hammersmith, second. 2. For the best collection of twelve miscellaneous plants in flower. In this class a very effective exhibition was made by Mr. William Paul, of Waltham Cross. It consisted of a successfully bloomed pink Hawthorn, *Prunus sinensis*, *Rhododendron fastuosum*, *Deutzia crenata* fl. pl., *Rhododendron candidum*, *Azalea Belle Gantoise*, *Roi Leopold*, and *Beaute de Ledeberg*, *Kalmia latifolia*, *Diosma purpurea*, and *Cinerarias*. This received the first prize.

Mr. Young received extra prizes for collections of twelve Hyacinths, distinct, and for five *Amaryllis* in pots, and one also for a tray of *Camellia* blooms. Messrs. J. & C. Lee, of Hammersmith, also exhibited a tray of *Camellia* blooms of great beauty, among which were the lovely *Lavinia Maggi*, *Valtevedora*, and *Countess of Orkney*, and these received an extra prize. Mr. Reeves, of Ladbrake Nursery, Notting Hill, received an extra prize for six handsome plants of *Deutzia gracilis*. Messrs. Lucking, Brothers, received a first-class certificate for a fine collection of forced flowers.

DAPHNE INDICA.

I often wish that a plant of such easy culture as this were more grown, for it is a general favourite. As soon as the shoots are 2 or 3 inches long slip them off with a bit of heel, and plunge in a stove or Cucumber-bed; they will soon take root. Then pot them off, and keep close for a few days, and when the plants are well rooted in their pots pinch out the top of each, and place them in a house or, better, a pit. They will soon shoot out, and when they have grown 3 or 4 inches pinch off the leading bud of each shoot; by doing this twice or thrice nice bushy plants can be secured the first season, and these will always bloom in the following year if the wood be properly ripened. By following the same plan a second year the plants will be quite large. This system does not seem to weaken them, as their leathery leaves and strong shoots indicate that they are in good health.—W. C.

FAILURE OF THE VERBENA.

If gardeners could carry out the plan of your worthy contributor, Mr. Robson—namely, giving a change of soil and situation, I have little doubt that it would go far not only to prevent the failure of the Verbena, but to improve all other bedding plants. In proof I can give an instance that came under my own observation. Not quite two years ago I entered my present situation, and knowing that there was a scarcity of

Verbenas at the place, I brought cuttings of ten varieties which I had grown for three years. I had them struck in 48-sized pots, and in the spring I took cuttings from them, and throughout the hot weather last summer the plants were a mass of bloom, while those which I found at the place dwindled away in the beds, and before summer was over had to be pulled up and thrown to the rubbish heap.

Verbenas have never succeeded better with me than they have done this winter; the mildness of the season caused them to throw out strong short-jointed shoots for cuttings without any extra heat. In putting the cuttings in if I find any insect on them they are drawn through a little tobacco water. The following I have always found to keep well through the winter:—Deniauce, Purple King, Annie Laurie, Tommy, Mrs. Woodroof, Rosa, Snowflake, Laly Palmerston, Impératrice Elizabeth, and Beauty of Acton, a seedling of my own raising.—R. HOLLIDAY, *The Elms, Acton.*

PLANTING VINES.

In answer to your correspondent "INQUIRER," I beg to detail the following experiment, as bearing on his question.

About ten years ago I had occasion to plant three large vineries, the borders being made of the best materials within my reach. I selected strong canes one year old, which were cut down to one or two eyes in autumn. Early in February they were started into growth, receiving from time to time a liberal shift, and being plunged in a gentle bottom heat.

About the first week in May I had a trench cut in the border close to the front wall, about 2½ feet wide by 3 feet deep, and filled it with well-prepared stable-manure. When the heat had a little subsided, the ridge of dung was covered with soil. The Vines turned out of the pots, the roots carefully spread out, and the Vines shaded for a few days. The operation much resembled the planting of Melons in an ordinary dung-frame. The result has been most satisfactory. Stimulated by the gentle bottom heat the Vines grew vigorously, and I had the satisfaction of cutting very fine bunches fit for table sixteen months after planting.—A. McK.

NOTES ON BEDDING-OUT.

As we are all now settling in our minds what our planting-out is to be, I should like to invite a few papers from your correspondents on the subject of last year's results, chiefly as respects ornamental-leaved plants.

Though my experience is on a limited scale, still, as I live in a very ungenial climate, and with one of the worst soils in Ireland, it may not be uninteresting to note down what I know will give satisfaction. *Coleus Verschaffelti*, I find, will succeed well in a sheltered situation. I had some very wretched plants which it was not my intention to have made use of, but, having an empty bed, I put them into it on the 20th of July. By the 15th of August they had covered the bed, though they had scarcely a leaf on them when they were planted out. The colour from that time till the frost killed them could not be surpassed.

Amaranthus melancholicus ruber grew stronger than I ever saw it, rather more than 3 feet high, and broad in proportion. I certainly think, however, that its colour was not so good as it was the first year I had it, being more of the ruby and the copper. Is the plant, like *Perilla*, gradually losing its beauty in our climate? or was this simply the fault of the seed? I am inclined to think the latter was the case, for some plants which sowed themselves in another bed, where it had been for the last two years, were decidedly better in colour.

Iresine Herbstii did very well, retaining its beauty longer than either of its rivals, and improving in colour as the season advanced.

The *Amaranthus* lost its beauty by the 19th of September, though it was not killed till October 21th. The *Iresine* was killed about ten days later, and the *Coleus* on October 14th.

Have any of your correspondents tried *Amaranthus tricolor*? I intend to attempt it this year, though my neighbours laugh at me, and say it will not do; surely it cannot be more delicate than *Coleus Verschaffelti*.

I found that no *Caleolarias* stood the dry weather last season so well as *Victor Emmanuel*, and it is a very handsome variety. *Cloth of Gold Geranium* did splendidly, it was put out on the 24th of May. I find that this *Geranium* suffers more from transplanting than any other variety. It always

with me takes a full month to recover itself, but after that is grand for the rest of the season. Its effect at a little distance is quite equal to a bed of *Caleolarias*, and I need not say infinitely more lasting.

In a dry season *Cockscombs*, with a double band of snow-white *Chrysanthemum*-flowered *Asters*, are lovely.

I should like to know which is the better *Oxalis*, I mean as to colour of leaves—"corniculata atropurpurea" or "tropaeoloides;" and whether would *Cloth of Gold* or *Bijou Geraniums* be the better edging to a bed of *Kicinus sanguineus glaucus*?—Q. Q.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

HABRANTHUS FULGENS (Brilliant Habranthus).—*Nat. ord.*, *Amaryllidaceae*. *Limn.*, Hexandria Monogynia. Native of tropical and southern extra-tropical America. Flowers scarlet, with yellow centre and tube. Introduced by Messrs. Backhouse, York.—(*Bot. Mag.*, t. 5563.)

DENDROBIUM DIXANTHUM (Double-tinted Yellow Dendrobium).—*Nat. ord.*, *Orchidaceae*. *Limn.*, Gynandria Monandria. Native of Moulmein. Introduced by Messrs. Low & Co., Clapton. There are two tints of yellow in the flowers.—(*Ibid.*, t. 5564.)

GLADIOLUS PAPILLO (Butterfly-flowered Gladiolus).—*Nat. ord.*, *Iridaceae*. *Limn.*, Hexandria Monogynia. From the Cape of Good Hope. Flowers various tints of pink, yellow, and purplish crimson.—(*Ibid.*, t. 5565.)

PERISTROPHE LANCEOLARIA (Lance-leaved Peristrophe).—*Nat. ord.*, *Acanthaceae*. *Limn.*, Diandria Monogynia. Native of Moulmein. Herbaceous. Flowers pale purple.—(*Ibid.*, t. 5566.)

BATEMANNIA GRANDIFLORA (Large-flowered Batemannia).—*Nat. ord.*, *Orchidaceae*. *Limn.*, Gynandria Monandria. Native of low elevations in New Granada. Flowers white variously streaked with purple, and stained with yellow.—(*Ibid.*, t. 5567.)

SPHACELE CERULEA.—*Nat. ord.*, *Labiatae*. Flowers pale purple. Very like a *Stachys*. Probably a native of Chili.—(*Floral Mag.*, pl. 281.)

NERINE FOTHERGILLII.—Scarlet-flowered. A very old kind.—(*Ibid.*, pl. 282.)

MARANTA ROSEA-PICTA.—Native of equatorial regions of the upper Amazon, between Loreta and Iquitos. Leaves of darkest sap-green, with the midrib, and a band near the margin, pink.—(*Ibid.*, pl. 283.)

POMPONE CHRYSANTHEMUMS.—The following are introduced by Mr. Salter, Versailles Nursery. *Fairy Nymph*, white. *Rose d'Amour*, white, with rosy-tipped petals. *Torrida*, golden yellow.—(*Ibid.*, pl. 284.)

LOBELIAS.—*Distinction*, rose cerise, with pink shade. *Peach-blossom*, beautiful peach-blossom colour.—(*Florist and Pomologist.*)

HOUSE-CULTURE OF CUCUMBERS.

FULLY agreeing in the truth of the sentiment expressed by Mr. Read, "that discussion and inter-communication will do much to advance the cause of gardeners and gardening," and having read with interest "PETER'S" account of his system of cultivating Cucumbers (although I must say I wish he had been a little more explicit), I venture to send a few remarks descriptive of my own system of management.

Mine is a six-sided house, four sides of the roof being double-glazed; the other two, towards the north and overhung by trees, are slated; the sides are single-glazed. It is fully exposed to the east, south, and south-west, and from its peculiar shape is adapted to catch every gleam of sunshine; it is, therefore, very suitable for the winter forcing of Cucumbers. It is heated by one of Pierce's patent boilers. The eight-inch flow-pipe passes through a chamber covered with slate; on this is a layer of fine sand, which affords a nice bottom heat for propagating-purposes, and, being kept constantly moist, insures a humid atmosphere. The return, a single four-inch pipe, is brought out of the chamber and carried round the house for surface heat. The bed being on the north side, and generally occupied with other things, I am reduced to the necessity of growing my Cucumbers in pots, and by following the system I shall detail, I have been very successful.

I am expected to keep up a constant supply of good Cucumbers from the middle of October till June, and to accomplish this, I commence operations about the last week in July by sowing some seeds singly in small pots, placing them in a comparatively cool house. The young plants soon make their

appearance. When one rough leaf is formed, I repot them into four-inch pots, using a rather rich compost; and as they grow they are tied loosely to a small stick till about 18 inches high, when they are stopped. They are then ready for their fruiting-pots. For this purpose I use pots of about 15 inches in diameter, thoroughly drained with potsherds and broken bricks. Now for the soil. While the plants have been growing the soil has been undergoing a little preparation. Unlike "PETER," I prefer fresh-cut turf which has been a week or so in the middle of a bed of strong fermenting horse-droppings; by this means it is heated sufficiently to kill all the roots of grass, &c., contained in it, and becomes highly charged with ammonia. I use this in a rough, lumpy state, warm and steaming from the heap, without any admixture whatever; the roots immediately strike into it, and the plants grow amazingly. At first I only just cover the ball, adding more soil as the roots advance. When the soil in the pots becomes exhausted, I top-dress with a little of the same kind of soil, and water with liquid manure.

When the plants throw out their laterals I only leave the upper three or four, and as the plants grow and spread I stop every shoot at the first joint, unless wanted for cuttings. About the middle of December, and sometimes earlier, I commence taking cuttings whenever an opportunity offers, to replace any plants that may seem exhausted or weakly, which they will sometimes be during the dark days of winter, in spite of the utmost care. This plan of replacing worn-out plants with vigorous young stock must be closely followed if handsome fruit be desired.

The plants are never syringed, but a moist atmosphere is insured by copious sprinklings of the bed, pipes, and floor twice or thrice a-day. The thermometer is never allowed to exceed 70° with fire heat. It sometimes rises to 85°, and even 90° by sun heat. The average night temperature is 58°. The pots stand on a slate slab close to the front lights, and are kept about an inch above the slate by some pieces of tile in order to allow the warm air of the house to circulate under as well as around them, and also to insure a free drainage. I have tried many soils, but find nothing to excel, or, indeed, equal the *Sion House Improved*. Perhaps at no distant date I shall give the details of my practice in growing and ripening a crop of Melons in pots, in the same house, in the intervening months.

Will "PETER" kindly give us a few more particulars as to temperature, what depth of cotton waste he uses, &c.?—
PETER'S BROTHER.

RAIDS AFTER FERNS.—No. 4.

WINTER RAID.—TEIGNMOUTH.

ABOUT fifteen miles west of Exeter the English Channel takes a gentle sweep inland; lapping up to the base of old red sandstone cliffs and leaping over a sandbar, it carries its salt waters by the side of a Fir-crowned headland, called the Ness, into the picturesque river Teign, which proudly swells itself into lake-like proportions at high water, giving additional loveliness to meadows of emerald, and corn fields golden in summer and ruby-coloured in winter. Facing the east, with a barren sandy flat, called the Den, in front, where wild-beast shows contend for pre-eminence with photographic studios and uproarious games of football, there are crescents, and places, and Belle Vues, and public rooms, and baths, sheltering a bright little town of about six thousand inhabitants which finds congregations for two English and one Roman Catholic church, and for chapels of a variety of incongruous theological opinions.

Teignmouth, or, as it is called, Timmuth, is a town of considerable spirit, which develops itself in sundry spasmodic efforts to distinguish itself, in many of which it succeeds with tolerable effect. It has its lifeboat, which presents a "very swashing and martial outside" to the beholders as it is occasionally paraded through the town on a triumphal car, looking so very bright and new as to be suggestive rather of sunshine and blue seas, than of those grand heroic times when Devonshire Drake gained a world's applause by his deeds of sailor daring. A pier is in course of building, which will bring yachts, and a still greater number of pleasure-seekers; while the good drainage and salubrious air invite those who are seeking for health, and who, with care, may enjoy a happy combination of health and pleasure.

The amusements are, perhaps, scarcely of the same austere nature as those of its sister watering-place Torquay. Concerts and balls are of rare occurrence, and but moderately

attended; but there are plenty of cheap entertainments, and the public who one day pay a shilling to see spiritualism in full blow, the next day pay another to have their new-born faith shivered to atoms, and one is inclined to wonder how any errors exist, so many shillings are paid to have them exposed; M. Debbler cuts the Gordian knot that binds the Davenport brothers, and Signor Gavazzi takes away all standing-ground from under the Pope's revered toe; and every error picks the pocket of its neighbour. And, lest these amusements should not suffice for all minds, Nature has stepped in, supplying others with a literal hand, so that few places have a greater share of them than Teignmouth. Beautiful madrepores strew the shore across the ferry at Labrador, and sea beasts and rare seaweeds and shells are to be found lurking amongst the sea-laved rocks.

Within a pleasant walk there is a sandy waste called the Warren, which furnishes many rare wild flowers, amongst them the little pale blue *Trichonema columae*, or *Bulboodium*, the Warren being its only English habitat, and it resists every endeavour to naturalise it in other soil.

The winter in Teignmouth scarcely deserves the name of winter, some flowers grace every month of the year, and ere February blows itself into March the *Galanthus nivalis* follows the wake of the *Primula vulgaris* and the *Vinca minor*; the *Viola palustris* encroaches on the white *V. odorata*, and the *Narcissus pseudo-narcissus* weeps at the loss of its neighbour the sweet-scented *Peta-sites vulgaris*; while in the hedge-bank the fragile tiny *Potentilla fragariastrum* is the herald of the more welcome *Fragaria vesca*, which promises not only beauty in spring, but also a fruitful summer. The winter in Teignmouth has all these, and added to these it has its Ferns.

When the *Filix-mas*, the *Filix-femina*, and the *La-treas* are for the most part gone underground to see their mother root, the more hardy *Polystichum* still flourishes, and furnishes many a beautiful variety to reward the patient hunter. Nor is the decoration of Fern-land left to the *Polystichums* alone, the *Asplenium adiantum nigrum* may be sought after with great effect, the absence of other leaves and blossoms making its bright fronds all the more apparent. *Aspleniums trichomanes* and *marinum* may also be found; but where? *Marinum* has a wayward choice, and has located herself in the tunnels of the railway, where hardy spirits, furnished with permission and a lantern, may find her. In the overhanging cliffs she also makes her home, but is fast disappearing beneath the keen eyes of Fern-collectors. But it is not on the walls of railway tunnels, nor on the scarped cliff that my winter raids are made, but up sheltered lanes, whose high banks, covered with grassy foliage, from which delicate blossoms shine like stars, afford thousands of specimens of the, *par excellence*, Devonshire Fern.

The evergreen character of the *Polystichum angulare*, with its endless variations of delicately chiselled fronds, must ever make it a general favourite. There is, first, its common form, soft, feathery, lanceolate fronds, bi-pinnate, or divided into pinnae, and these again into pinnules, which are attached by a distinct stalk to the rachis of the pinna; the shape of the little pinnules somewhat obtuse, with an ear-like projection at the base, running in an outward direction towards the apex; each pinnule serrate, and the serratures have bristles; the sori terminal or on the upper part of the frond. Should there be any distinct departure from the above description, such as the anterior basal pinnules being much larger than the others, or divided again, thus becoming tri-pinnate, or nearly tri-pinnate, the Fern-collector will at once know that he has a variety of the species, and not the original type. The Teignmouth lanes furnish a goodly company of these beautiful varieties, each presenting some distinct feature, which separates it entirely from any approximating form.

As I was lately hunting up the Holoomb lane I chanced to meet with a magnificent specimen of decompositum, of all the varieties of *P. angulare* the most free-growing and jolly-looking; it rivals *subtripinnatum* in size, but the latter has a stiffer growth, and its pinnules are more acute. Soon after I came on *subtripinnatum*, and for the moment I thought I had found *tripinnatum*, so much divided were the basal pinnules, but as the little pinnules had no distinct and separate stalk, my first transport settled down into a quiet satisfaction, and I was rewarded by finding a little further on the pretty *hastulatum*. In this variety the entire frond is so finely and regularly cut that when held up to the light it appears like lacework; the pinnules are small, distinct, sharp in outline, and with a lobe or ear which stands out clear of the next pinnule. Still further on I found *Polystichum angulare acutum*, the name of which defines its character, the apex of frond, pinna, and pinnule being acute

in a very remarkable degree—so acute, that having once heard the name I think no one could mistake the Fern.

But it is not Ferns only that I have found in that Holcomb lane. Wandering there one day we came on a poor, almost shoeless, footsore sailor lad; looking so tired and hungry, we stopped to speak to him. A stranger, knowing no word of English, he told us in French that he was from Holland, and on his way to Plymouth. Walking from Exeter he had lost his way. "Had he money?" Only a few halfpence, but he did not wish for more. "Oh, no," he said, when we offered him silver; "you see I did not beg. You know I did not beg." He spoke so vehemently that I wondered; so I said, "Certainly you did not beg; but, nevertheless, accept a little gift." "Oh! no, it was not possible. He was only out of Exeter jail that very morning because he had found himself without silver, and demanded some. Ah! he did not like England, she was hard to strangers. He was hungry, and he could not beg." I looked in the honest face and believed the lad, so we took him home. He had never seen an English home. I offered him a chair. "Never, never in your presence," he said. We gave him meat and bread, and spirits, and then we took him to the railway, and gave him a ticket to Plymouth, with money for a night's lodging. Tears came in the poor fellow's eyes. It could not be true. He had never seen me before. Was I English? and then he added softly, when I told him why it was, "Yes, yes, I also have a home, and a sister married to a pastor." And so we parted, never to know each other's name on earth; and I often wonder how the Dutch lad will describe the party who helped him in his need; for verily it must have seemed a strange one, that party of ladies and gentlemen armed with steel weapons and huge baskets, searching so diligently for weeds in the heiderows of England.

Within a walk of Teignmouth I have lately found *Polystichum angulare intermedium*, and, I believe, *biserratum*. The

texture of these Ferns, so far as my experience goes, differs considerably from those of other varieties of *P. angulare*; both primary and secondary rachides are stiff, and the pinnules are connected with the rachis in all but the lower pinnae by a winged stalk. I found in the same hedge dissimilar: this is a very curious variety, the pinnae being scarcely in any two alike; some are forked at the end, some do not contain more than five or six pinnules, while others end abruptly in only two; the pinnules are also different in shape and size, while the texture of the whole frond is something like that of *intermedium*.

Another very interesting variety of *Polystichum angulare* growing near Teignmouth is the densely pinnuled *quadratum*, with its stiff narrowish fronds, the pinnae of which have imbricated pinnules, neat, roundabout little things, the ear-like lobe of which hides itself beneath its neighbour's sheltering wing. It is unlike any other variety known to me, and had not a high authority named it for me, I fear I should have called it *imbriatum*; but this latter has a slightly "winged petiole," which *quadratum* has not; moreover the basal anterior pinnule is but a trifle larger than those next succeeding.

Other varieties that I have found still remain unnamed, and I doubt not but that there are many others still to be found. The beautiful forms of *proliferum* Wollastoni and *cristatum* are natives of Devonshire, and to these *Holeana* has lately been added, the latter being found within a few miles of Teignmouth.

Of the *Asplenium adiantum nigrum*, Teignmouth furnishes many a goodly specimen. I have found them acute and obtuse, with intermediate forms. The *flabellatum* was found near Bishop's Teignton, and the *Bellairsie*, in the neighbourhood of Haldon; and all the Ferns that have been enumerated can be found on a winter's raid while inhaling purest oxygen with a fair mixture of ozone (if ozone can be exhibited in winter!) is one of its component parts.—FERN-HUNTRUSS.

FLOWER-BORDER.

I VISITED a friend of mine a few days ago, who showed me a flower-border plan, which I send. It struck me at the time as being well adapted for planting bulbs in the small compartments, bedding plants in the large ones, and standard Roses in the circles. In winter it is eligible for coloured materials in the small compartments and in the circles, with some nice dwarf plants in the beds. With a judicious arrangement it would look well all the year. It is not laid out at any place to my knowledge.

It may not be out of place for me to describe the sort of compasses I use when doing such work. It is nearly similar to the beam compasses described in the "Gardener's Assistant," at page 134. I took a piece of deal board 1 inch thick, 2½ inches wide, and 10 feet long; I cut it straight along the middle from end to end; then I took a piece of elder wood 2½ inches long, removed the pith, and tied it at the end of the beam between the two sides. I then took two pegs, one

about 12 inches long, and the other about 8 inches in length. The end of the long peg, *a*, I cut quite round, so as to turn freely in the elder, and the end of the other peg I cut

Beam-compasses.

flat nearly to the same thickness as the elder, and so that the beam would rest on the shoulder, as shown at *b* in the engraving. To secure the peg, *b*, from moving from its place, I cut a piece out of it above the beam, so as to form an eye, as at *b*. I then made a pin in the shape of a label, with one end smaller than the other, so as to put it in the eye above the beam to tighten it. There is no trouble in pulling the pin back, shifting the peg to the required place, and putting the pin back again. It is scarcely

necessary to say that the peg, *a*, is put into the ground in a perpendicular position, and the elder end of the shaft dropped down on it, so as to revolve around it as the axis. The peg, *b*, describes the circle, and passes over any peg that may be put in the ground to mark other parts of the figure.—M. O'DONNELL.

WORK FOR THE WEEK.

KITCHEN GARDEN.

DURING the last month we have had such a continuance of wet and unsettled weather that little progress has been made in the sowing of seeds, or even the digging and trenching of ground. The late drenching rains will convince the owner and occupier of every plot of ground, of the necessity and importance of thorough drainage. Ground that is thoroughly drained takes but a few hours to drain off the superfluous moisture, and, under such circumstances, it is soon in working condition;

whereas, ground that is imperfectly drained will be days, and in some instances weeks, before it be in a fit state for the reception of seeds. The gardener who has his ground thoroughly drained will have his crops appearing above the surface before those whose ground is undrained will be able to deposit the seed. Proceed without delay at every favourable opportunity in preparing and cropping the ground, according to last month's directions. After the late rains it will be advisable to pass a heavy roller over the gravel walks to set and bind them well for

the season. Take every opportunity to destroy slugs, which the recent rains have brought out from their winter quarters in abundance; the use of quacklime on a warm evening after a showery day, is a well-known remedy. *Beet*, sow a little Red, but not much, as the chances are that it will run to seed. *Broccoli*, make the principal sowing of favourite sorts to stand the winter; a sowing of the Dwarf Hardy Russian made a fortnight hence often bears frost better than earlier sowings. *Cauliflowers*, continue to plant out the strongest plants kept through the winter; those which have been brought on under hand-lights will be getting sufficiently advanced to be benefited by applications of liquid manure to keep them in a free-growing state, otherwise we may expect some to butt on. Let the soil be constantly stirred about them. *Carrots*, the main crop of the Long Red or Altringham for winter use, ought to be sown in deeply-trenched ground. *Kidney Beans*, put in a small breadth of some early sort on a warm, dry, sheltered border, and plant a quantity in small pots, to be raised in a cold frame, and planted out as soon as danger of frost is over. *Onions*, if the main crop is not sown, the first opportunity of doing so must be embraced. *Peas*, continue to earth-up and stake as they advance. Take care that those just coming up do not want for surface-stirring, which will be the more necessary after heavy, dashing rains, which consolidate the surface of the soil. Make successional sowings of Radishes and salads; small sowings are best, each made as soon as the other is up. Thin out, and transplant where desirable, all seedling crops sufficiently advanced.

FRUIT GARDEN.

The disbudging of Peaches and Apricots must be commenced forthwith by removing all the foregoing wood shoots, and a portion of those on the lower side of each shoot also. As blossom-buds are very thick this year, it will be proper to take off a portion of these where ill-placed. Keep a sharp look-out for aphids on the young shoots. After high winds, fresh-planted trees in the open quarters should be finally looked over, and the earth pressed firmly about them. The observations made last week on the subject of disbudging had reference to Peaches and Nectarines, and I will now concisely resume it. As the trees advance in age, and require a full complement of wood, and circumference according to the space allotted to them, it will be found necessary to pursue this system of disbudging with still greater severity, in order that the trees may be maintained in a healthy, fruit-bearing condition, and not weakened by crowding with too much wood. For this end we must encourage only the young shoot nearest the base of the fruit-bearing shoot; but as the terminal shoot will be necessary for the proper maturation of the fruit, it must be closely stopped at the last thinning, and any attempt at growing afterwards must be carefully removed, so as not to injure the leaves. As soon as the fruit is gathered, it is best to remove these stopped shoots down to the young ones, which are greatly strengthened thereby, and it also exposes the young wood more to the influence of the sun at a season when the exposure is most needed for its ripening.

FLOWER GARDEN.

Commence in earnest with mowing, and cut down close; the grass will then mow better all the season. Finish edging walks, clip Box-edgings, plant Gladioluses and Ferrarias, plant evergreen shrubs, if you are obliged; and, if so, take care to have every fibre carefully preserved, have great balls of earth and holes dug much larger than the ball will fit into. Attend well to watering, and fix the stakes to prevent the injurious effects of the plants being windwaved. In planting shrubs and trees, if due care is not taken, disappointment will surely follow; therefore do whatever has to be done quickly, and, let me add, do it well. It is now a good time to plant that stately flower the Hollyhock, which suffers much from frost if planted too early. We have no hesitation in recommending this noble flower to be much more extensively cultivated than it is. It is used very extensively in Battersea Park, and to those who have seen it there during its flowering season no eulogium can be necessary.

GREENHOUSE AND CONSERVATORY.

Pelargoniums, herbaceous Calceolarias, and Fuchsias are now advancing rapidly, and the early plants of the former two are showing blossoms. Take care to stake and tie the plants neatly without loss of time, and some of the old growers say that manure water is good for them after Good Friday. This, however, I think, depends more upon the pots being filled with roots than the day of the year. One of the best growers of the

Pelargonium never watered with manure water until the trusses were up and the pots filled with roots. Fuchsias will now be the better of a little shade during bright sunshine, and very liberal treatment will not be thrown away upon them. The shifting of all specimen plants should be now completed. Too much care cannot be taken in watering to see that the water does not escape by the side without moistening the old ball, also to guard against over or under-doing the supply. Keep a moist atmosphere, sprinkling the plants with tepid water once or twice a-week, and pay due attention to the extermination of insects directly you can perceive them. If the plants in the borders of the conservatory are dry, or any of the climbers, give them a good soaking of weak tepid manure water. Sow liberally Chinese Primroses and Cinerarias; these well attended to will make strong autumn-flowering plants. The Himalayan *Primula denticulata*, although hardy, forms a nice dressy little plant for the mixed greenhouse. Let Camellias making wood be shaded and frequently syringed. Those who wish to have Camellias in blossom from October to May must take care to force their plants into wood successively. If a given stock be divided into three portions, one portion to be subjected to this process in February, a second in March, and a third in April, the object will be effectually accomplished, provided the subsequent treatment be what it ought to be.

PITS AND FRAMES.

Continue potting-off stock for the flower garden, also making cuttings constantly of Verbenas, Fuchsias, Petunias, Dahlias, Geraniums, &c.; they will all be wanted for some purpose. Shade newly-potted Stocks, and more especially cuttings, carefully; and remember that in making cuttings the leaf should not be first allowed to flag, and then an attempt be made to restore it by abundance of water; the leaf must never be allowed to droop. See that such climbers as Rhodochiton, Manrandya, Lophospermum, Tropaeolum, &c., are propagated and cultivated for blanks or trellissing, &c.—W. KESSL.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

A few dry days and a bright sun have done much to dry the soaked ground, and prepare it for the reception of Onion and other seeds, such as those of greens, Broccoli, Peas, and Beans. There are just now many complaints of the vast extent of catalogues of seeds that perplex by their very variety. For small gardens especially we may mention what, if received true, will not be likely to disappoint.

Onions.—Sow James's Keeping and White Spanish, and Silver-skinned for pickling.

Garden Beans.—Early Mazagan for earliest and latest crops, Longpod and Green Windsor for summer, and the Dwarf Fan where there is little room, as the Beans may be grown in rows a foot apart.

Peas.—Dillistone's Early and Sangster's No. 1 for earliness, the first the earlier, the second the better bearer; Ne Plus Ultra the best for a late Pea. Burbidge's Eclipse, Veitch's Perfection, and Harrison's Perfection are fine medium-height Peas; and Dickson's Favourite is a good Pea that bears heavily, is of fair flavour, and comes in between Sangster's and the earliest Marrowfats. Dwarf Peas, as Tom Thumb, Bishop's Longpod, &c., are useful chiefly where room must be economised. They come in early at the foot of a fence in a warm place.

Carrots, we will only sow moderately as yet. We prefer the Early Horn, the Long Surrey, and the Altringham. In rather stiff thinish soil the Horn often does wonders, when the longer kinds come forked.

Parsnips should be sown as soon as possible. We prefer the Hollow-crowned; the Student comes of a large size, but sometimes it is a little hard at the core.

Cabbages. Some of the Battersea may be sown for summer use. We prefer for the main crops Atkins's Matchless when it can be obtained true; ours has not been so for some time, and our ground is too small for seed-saving. The Rosette Colewort is the best to sow in May for autumn and early winter use.

Cauliflowers.—Not to perplex, we find the London Early Cauliflower suitable for all sowings.

Broccoli.—Cauliflower Broccoli, Snow's Winter Broccoli, Early Purple Sprouting, Willecock, and Miller's Dwarf White will furnish a good supply.

Brussels.—For one sort choose Scotch Cabbaging Kale. Cot-tager's Kale is good, and the Variegated pretty.

Brussels Sprouts.—The common, from imported seed, is still, all things considered, the best. The Dutch varieties are good; but on the whole are not so profitable for general purposes.

Turnips.—A few White Dutch. For main garden crops the American Red Top is the best, sweetest, and most crisp.

Leeks.—The Musselburgh is as good as any.

Radishes.—We almost entirely use three sorts—Scarlet Short-top, and White and Red Turnip-rooted.

Kidney Beans.—Unless in warm places it is too early to sow Kidney Beans out of doors. In our opinion nothing beats the China Dwarf, called often Robin's Egg, for general purposes. Next is the Cream-coloured; and the Newington to be gathered young and cooked whole. Scarlet Runners of course.

Celery.—Incomparable White for main crops, it takes so little room, should now be sown under glass, if possible—a hand-light will do. Cole's and other varieties are much larger.

Spinach.—Round-leaved, and round-seeded, for summer, Prickly-seeded, or Flanders, in autumn for winter.

These are the seeds to which attention must now be chiefly directed, and more depends on getting them into the ground in good condition than sowing them very early, when the ground is in a clammy wet state. A little time lost in sowing is soon made up if the ground is nice, sweet, and mellow. A great deal of seed is destroyed by being put into the ground when this is in a wet clammy state. There is the risk when at all deeply covered that the seed absorb so much moisture as to rot, and besides, if the soil is rather stiff, the seed is wrapped in it, as in a piece of soft indian-rubber, and perishes for want of air and its oxygen reaching it. Ground so puddled will scarcely become kindly all the season, as rains do not pass freely through it. Seeds sown in nice, dry, mellow soil scarcely ever suffer from wet afterwards, as the showers pass freely through it. All these considerations point to the importance of having some March and April dust for seed time. We mean not dust on the fields and gardens, but dust on the highways, for if the soil is too dry the germination of the seeds is unduly arrested.

Ran the hoe through growing crops, and hoed and raked some walks that from being shaded had become a little green. Swept the others hard to give them a fresh appearance, and will fill up some blanks in the edgings as soon as possible.

Gave a little more earth to Potatoes in frames, as the tubers were running rather near the surface; watered Peas in pots in an orchard-house beginning to show bloom; gave abundance of air in sunny days to Radishes, Carrots, Lettuces, Cauliflowers, &c. Sudden changes affect all plants under glass less or more. In the brightest sun of Tuesday, after a period of dull weather, Potatoes, Kidney Beans, &c., began to flag, though the examination of the soil showed they were quite moist enough. A slight syringing and slight shade for a couple of hours made them all right. After a course of dull weather the plants are unable to bear the rapid evaporation which the sun so suddenly causes, and hence a slight shading will often be of great use for short periods under such circumstances. The great point is to allow the shade to remain no longer than is absolutely necessary, as all growth in shade is comparatively weakly.

Spawnd a piece of a shallow Mushroom-bed, and prepared a piece more with fresh material, working up a part of the old bed with the fresh dung, owing to being scarce of materials. The only objection to these shallow beds is that they generally do not bear long, or regularly, and hence the necessity of successions. One reason why we make even these shallow beds of poorer materials than we used to do, is to humour the prejudice for thinnish Mushrooms. The thick, fat, juicy fellows which we used to delight in, do not suit every one. For Sea-kale, Rhubarb, &c., see previous weeks.

FRUIT GARDEN.

As to general work, we are rather behind with nailing, &c., out of doors. We deferred pruning Gooseberries, and we presume the delay will matter little, as after all our washing, and dredging, and stringing, the birds will have it pretty well their own way. We stated the other week, and repeat it, that if gardens are to be made preserves for game, they will soon be little else than preserves for that game and its attendant vermin. There is scarcely even a Laurel bush that does not become the roosting-place for at least its hundred of small birds. Not only do Pear trees, &c., suffer terribly, but we noticed that some nice Thorn trees were having the most forward buds regularly picked out. As a rule, no class in the community are greater admirers of the little birds than gardeners; but when there are innumerable thousands instead of

scores, and trees loaded with bloom-buds to-day are cleared pretty well to-morrow, a man begins to feel that he may have too much of the poetry of birds. It is of very little use netting under such circumstances. Do what you will the birds will find their way under it, and take what they want, and especially in the morning as soon as the day breaks. Under such circumstances there will be no safety except in securely netting vegetable and fruit gardens all over as high as the walls for a number of months in the year. Netting individual places seems only to entice the robbers to see what is there, and no fastening will keep them out.

The orchard-houses, especially the first, have been a picture, and Tuesday, with its powerful sun, and the free ventilation, would pretty well secure the setting of the fruit. There has been quite enough of wind to render any brushing of the strong prominent blooms unnecessary. This house we shut up early, the other is left open in favourable weather till bedtime. In the first house, Tuesday was the only day lately in which all our ventilating power was at command, as even now, and especially when the fruit is set, we will use more sun heat shut in, to bring the house on in succession to the Peach-house. The trees at the back will not be such a show after Tuesday, as the bright sun, and the breezes of wind, have caused a good many of the petals of the bloom to drop. No insect of any kind has as yet appeared. Judging from the frequent directions about smoking houses, plants, &c., the bill for tobacco must be no small affair in some places.

A few of the Tom Thumb Pea pots are showing bloom, and if there be a few sunny days a good many will be out. This Pea must be gathered early enough when under glass, or it is apt to eat hard. It must not be so large as it might be out of doors. The glass seems to harden it.

Peach-house.—Thinned out shoots, tied them, and exposed the fruit in the Peach-house. Took off a single twig carefully, as it had some curled leaves, and in these were a few green fly—the only appearance of anything in that shape not wanted that we have yet seen in the house; and removing the twig, which could be well spared, was better than washing or smoking. This house as yet has had nothing done to it for insects, because except on that twig none as yet have appeared. We had more than our share of them three years ago; and were we left untroubled this season, which it might be too much to expect, we would still in another season use such preventives as were detailed as being used in winter and spring.

This Peach-house, of which the roof is at an angle of 45°, is the best place for setting early Strawberries that we have, and a shelf of plants with the fruit swelling was cleared off to finish in the pits and vinery, and they were replaced by plants showing bloom from a pit and frame. This all makes work, but in the back of the Cucumber-pit we could swell the fruit more quickly, and with enough of light to flavour them, than we could do in the Peach-house, whilst neither in the Cucumber-pit nor the vinery could we give air enough to suit the Strawberry when setting. Owing to the gleams of sunshine the fruit has been good in flavour. We mention this shifting of the Strawberry plants to show that much may be done in this way in little room, but at the expense of a much greater amount of labour than when plants can be set in and perfect their crops in one place before being removed. A place for everything is by far the most economical as respects labour; but, then, to have a Strawberry-house, a Melon-house, a Fig-house, a Geranium-house, a Heath-house, a New Holland-house, a bedding-plant-house, a Rose-house, &c., involves a considerable sum for a first outlay, and this in general is so deterrent that the most that can be obtained from a small space is too often the great object, though that causes a greater amount of labour and of continued consideration. For Vines, Figs, &c., see previous weeks.

ORNAMENTAL DEPARTMENT.

Rolled the lawn and walks in pleasure grounds. Turned over ridges and numerous beds left rough for bedding plants. Pruned shrubs and Roses. All Briars for budding should now be planted. Picked up all wood and leaves broken and drifted by the late high winds; the half-rotten hotbed dung, consisting chiefly of tree leaves that had been used as a slight dressing for the beds, was turned down as above stated, by a very shallow spit of the spade, as if very dry it would blow about on the grass, and the birds would scratch it, and it had lain long enough exposed to be quite sweet enough for the purpose. The airing and sweetening of this slight surface-dressing is a matter important to success. Of course, for vegetables we should not like to waste its virtues on the air, but would dig it down at

once; but, as stated a week or two ago, it becomes rather a different matter when we wish abundance of bloom instead of mere luxuriance of foliage.

In cold pits too much air cannot be given in mild days to Auriculas, Carnations, Wallflowers, Stocks, and Mignonette sown in autumn. Fine useful Mignonette may be had by sowing now in a mild heat, with a rather close atmosphere until the plants are an inch in height. Now is a good time to sow or prick-off for bush or tree Mignonette in pots. Calceolarias want all the air possible. We have not yet been able to plant out, so as to thin the November-inserted cuttings, but we must do so ere long. Ran the fingers and then a pointed stick through the surface of Violet-beds, Neapolitan and others, to let the air into the soil, and render it sweeter. Of all Violets, the Neapolitan are our favourites for scent, but bunches of them and blues look very nice when placed alternately. We hope to have the new ones next season. The double blue is a great favourite with many. It has suffered much with us this year in the borders, owing to the excess of wet, and so has the Lily of the Valley, which, in general, can stand a good deal of moisture.

Pelargoniums in ainery which was becoming too hot for them have been removed to the conservatory, and the cold or late variety, which is beginning to bud sooner than we want it. The stage, &c., in the inery has been filled with variegated Geraniums, fresh-potted singly, to be turned out and hardened off afterwards, as there is plenty of light still for them, and the heat will bring them on a little. Newer kinds of Fuchsias have also been repotted and placed there, just to give them a move before they go to a colder place afterwards. In the inery farther advanced, the stage is covered with some forward variegated Geraniums, fine-leaved Begonias, just shifted, and Gloxinias the same, where, as the Geraniums are removed, the latter will find themselves at home in the heat and the comparative shade, whilst the syringing of the shelves and the floor will give enough of atmospheric moisture for them and the Vines. A little sweet dried caked cowdung, made rather fine, helps these Begonias and the Gloxinia very much, and the former often produce the finest leaves when rather under-potted, and in that state and size come in better for house decoration than when in larger pots. The leaves, also, will continue a long time fresh in a room when separated from the plant. In halls, &c., where there are no fires, Cinerarias will remain fresh a long time in pots, or planted in vases; but in winter and spring they stand a very short time in rooms with large fires that dry the air, unless the large leaves are frequently damped or sponged. For this purpose the older small-leaved kinds are the best. However fashionable it may be to stud entrance-halls, &c., with plants in bloom, the want of light alone makes them often look sadly out of place. Potted and divided Ferns, and fresh-packed baskets of Stanhopeas, and other Orchids, &c.

Propagating.—A good portion of the week, however, has been taken up in pricking out and propagating. In relation to a number of inquiries we may here shortly note a few points.

1st. Size of cuttings. Every joint of most plants may be made into a plant. Where there is a shoot or bud on each side of the joint, the joint may be split up the middle, and two plants made from it; but, like striking Geraniums from leaves, it is a wearisome process, and much time is lost before you obtain a fresh plant. We have no faith in striking Geraniums by leaves, unless there is a bit of the stem at the bottom of the leaf, and a bud there, either perceptible or imperceptible. Many plants, as Cucumbers and Melons, as well as Geraniums, will emit roots from leaves; but it is long, if ever, before they accumulate enough of organised material to throw up a fresh shoot. In general it is best to have cuttings from 1 to 3 inches in length.

2ndly. In making the cuttings, cut through at a joint with a clean knife. This cutting at a joint is necessary in all hollow-stemmed plants, and in all cases prevents liability to damping; remove the leaves then at that joint, and shorten those above them, allowing the rest to remain to continue growth. We would not remove many leaves at present, because,

3rdly. All cuttings at this season will strike faster if they receive an extra stimulus in the way of heat, but not so much as to over-excite the cutting to elongate upwards. The modes of obtaining this heat we will allude to next week.

4thly. In proportion to the leaves left on the cutting and the distance it stands from the glass, will shade or no shade be required. At present we have a number of lights in a pit filled closely with cuttings striking of Verbena, Lobelia, Ge-

raniums, Heliotropes, and Ageratums; only the lower leaves of the cuttings were removed, a few of the larger shortened, but most of the rest left on, and they have scarcely had a bit of shading. They stand from 15 to 18 inches from the glass, and in such a day as Tuesday they had a skiff once or twice from the syringe to lessen evaporation.

5thly. We like to see striking in water and sand and water, and it is a pretty amusement; but then the cuttings must be looked after as soon as the roots are formed, and transferred to nice, warm, sandy soil. When much is done it is as well to place the cuttings in material in which they will stand and flourish some time after they are struck, and hence we prefer, after good drainage, light sandy loam and a little leaf mould, with a slight coating of sand on the surface, which, if kept rather moist, will prevent air penetrating to and exhausting the base of the cutting. In proportion to the additional heat used in striking cuttings, so will greater care be required in hardening off the cuttings afterwards. Those with but few conveniences should do most of their propagating in summer and autumn. The sun will then give the heat which must now be supplied artificially by fire or fermenting material.—R. F.

COVENT GARDEN MARKET.—MARCH 31.

The den and has been somewhat more heavy in consequence of the requirements of the markets in the North for early Cabbages, out-door Lettuce, &c., and prices have therefore been maintained; but forced fruit has barely kept up to our former quotations.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nursery, Slough.—*General Spring Catalogue, 1866.*

J. A. Bruce & Co., Hamilton, Canada West.—*Descriptive Catalogue of Seeds for the Farm, Kitchen Garden, Flower Garden, &c.*

Ambroise Verschaffelt, Rue du Chaume, 50, Ghent.—*Précis-Courant pour Printemps et Été, 1866. Nos. 78—Plantes Nouvelles.*

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

S. G. S. FOR THE APPLE AND PEACH.—We have received a communication from Mr. Robson in answer to "T. R.," but too late for insertion in this week.

POLYANTHUS SPORT (A. Norwich).—Your Polyanthus has the calyx within one of larger size, rendering it more leaf-like. Such sports are not unusual.

ANNUALS TO BLOOM IN AUGUST (Litem).—We know of no plants which if sown now would bloom in June, or not until the end of that month. You do not say whether you have a hotbed, we therefore conclude you have not. The following, if sown now, will bloom from June to September:—Yellow: *Oxalis tropaeoloides*, chocolate-red leaves, neat for edgings; *Leptochloa aureus* and *luteus*, *Sphenogone speciosa*, *Sanvitalia procumbens*, which is a half-hardy annual, and *Tropeolum Tom Thumb*. Blue: *Nemophila insignis*, *Lupinus nanus*, *Whittalia grandiflora* and *Campanula speculum*. Scarlet: *Tropeolum Tom Thumb*, scarlet. Crimson: *Iberis atropurpurea kermesina*, *Tropeolum Tom Thumb*, crimson. White: *Nemophila insignis alba*, *Iberis grandiflora alba*, *Saponaria calabrica alba*. Purple: *Linaria bipartita splendens*, *Iberis umbellata*, *Campanula pentagonia*. Straw colour and cream are so much yellow that any lightish yellow will do for them, and we do not remember any. Rose and Pink: *Saponaria calabrica*, *Sileue pendula*. Lilac: *Clarkia elegans* and *Lupinus venustus*.

HOUSE FOR PROPAGATING AND CUCUMBERS (J. H. H.).—1st, We have no objection to the proposed arrangement of your house for Cucumbers, Melons, propagating, &c., and which is 35 feet long, 7 feet high at back, and 5 feet in front, and 10 feet wide, with a walk of 2 feet at back, a walk of like width and a shelf of 3 feet in front, which will leave a bed 5 feet wide, outside measure, in the centre of the house; but for getting conveniently to the shelf in front, it would be better if the house, both back and front, were from 9 to 12 inches higher. It is always unpleasant to have to stoop much in a house, and we are sometimes apt to forget to stoop in a low house, and not a few broken heads are the consequence. 2nd, Such a house would be very effectually heated by a wooden tank 14 feet wide, and 4 inches deep, supported on piers at from 24 to 30 inches from the ground. If the tank is made of 1½ or 2-inch deal, and well beaten together, and white or red leaded at the joints, we would not trouble with lining it with lead, though that is all right if expense is no object. Such a wooden tank, kept supplied with water, would last as long, and be as little subject to leakage as a cooler in a brewhouse constantly in use. Except red and white lead at the joints, we would use no paint inside or outside for a tank of this description. 3rd, Such a tank for Cucumbers and Melons might be set a few inches above the ground, and a box set on the top to hold soil, &c. The above height from the ground, from 24 to 30 inches, would be best for propagating, as being more handy for a shallower bed over the tank. 4th, The tank alone, with openings from the slate-covering to let up the heat, would be quite sufficient to heat that 10-foot house. There is no better plan for doing this than that described in Vol. II., Old Series, where much more was done by a wooden tank—namely, placing a wooden box, say 20 inches deep, over the tank, then putting 4 inches of rubble over the slate-covering, and a slight box of half-inch wood inside of the other, tarred and dried to prevent rotting, the inner box being separated from the outer box a couple of inches all round. Through this opening plenty of heat would rise to keep the house hot, and there would be no want of bottom heat. Water could also be poured down between the boxes to give moisture at will; but a mild vapour could also be obtained from a few openings in the slate-covering. Instead of a box 20 inches deep, we would prefer one 7 or 8 inches deep for propagating, so as to be nearer the slate-covering. To make the propagating-bed perfect, the deep box might slope like the roof and be covered with sashes, and then the cuttings could stand 8 or 10 inches from this inside sash-glass. Though the tank would be sufficient, yet to economise heat it would be best to take a small flue at least once through the house. 5th, The flue described at page 222, as heating the small pit, would not suit your proposed house, which is double the size. Such a flue going round your house would render you independent of top heat borrowed from your tank. Even were your flue deeper, as you propose—two bricks on the side instead of one, and did they abut against your bed in the centre, we fear they would not effectually heat that bed of 5 feet in width, unless at every 2 feet or so there were open drains underneath the bed communicating with the sides of the flue. 6th, As you evidently have a wish to dispense with boilers, tank, &c., if possible, we think your best plan would be to have a little pit in the middle of your house, as in page 222, take a flue 9 inches deep along the front, and for 6 or 8 feet build the sides with the brick on bed instead of brick on edge. Return that flue through the centre of the pit, and then either take it up the chimney or return it again at the back to a chimney at the other end. Pack each side of the flue in the pit with elikers, stones, &c., loosely, place a few inches on the top of the flue, and then cover all with an inch of fine, clean gravel, and on this you may place sand, ashes, or tan for propagating, and for Cucumbers and Melons. This would be the simplest and cheapest mode, and with a little attention will answer every purpose. The flue through or round the house, with a tank in the middle of the latter if there be nothing but a flue, if that is kept clean and sound. It is difficult to secure every advantage from any one plan. 7th, We will here also reply to "W. W.," who wishes to know if the pit represented at page 222 would not also do for Cucumbers all the winter. We doubt if it would; commencing in March, and fruiting in November and December, are very different. For winter work we should consider the pit too flat, the heat scarcely enough, and the walls too thin, unless indeed they were thatched with straw for the winter. Not having seen it tried, we can only say we doubt if it would answer. With the back wall some 18 inches higher, and the flues deeper or wider, we would be more sanguine as to winter success. It is as well not to drive even a model pit too far. Winter Cucumbers are most easily secured in light houses, if span-roofed all the better, and with plenty of heat to counteract cold weather. In such places they receive more light than can be obtained in pits in the winter months.

THE CHISWICK TRIAL OF PEAS.—Mr. Eley writes to us that with regard to the report on the trial of Peas at the Royal Horticultural Society's Gardens, some mistake has occurred respecting the Essex Rival Pea being represented as synonymous with the ordinary Early Frame, whereas there exists not a particle of similarity between these two Peas. Mr. Eley, the proprietor of the Essex Rival, would therefore respectfully beg of the public to suspend their judgment until they have seen the result of the Society's trial this year, the seed for which Mr. Eley hopes to furnish.

BOOKS (R. Y. A.).—You can have "The Cottage Gardener's Dictionary" free by post from our office if you enclose 6s. 8d., with your address.

CALCEOLARIA CUTTINGS NOT STRIKING (Edwin).—The cause of the cuttings not striking is most probably their suffering from green fly. Your dipping them in tobacco water, if it is at all strong, might destroy the insects. We strike all our *Calceolaria* cuttings in cold frames, putting about 3 inches of pit sand on 6 inches of soil, composed of one-half loam and one-half well-reduced leaf mould. Last year we put in the cuttings in the third week in October, gave them a good watering, and they have had nothing from that day to this, except air in mild weather, and a double covering of mats in severe weather, left on day and night until the plants were thawed, as they have been repeatedly frozen stiff. They are now strong plants, and not one cutting in a thousand has failed. Since we took to this system, for which we are indebted to Mr. Fish, we have not had so much as a green fly or insect of any kind; but when we struck and kept the cuttings during the winter in a heated house, they were eaten up by green fly and thrips. Victor Emmanuel is as easy to propagate as any other variety, and as easily kept over the winter. *Calceolarias* are almost hardy.

FORMING AN ARTESIAN WELL.—"A. Y. Z." wishes to know, when boring for water for a fountain, what sized pipes should be sunk so as to have a proper jet, and what is the general expense of boring. Who are the proper people to undertake this kind of work? Nothing of the kind ever being mentioned in *THE JOURNAL OF HORTICULTURE*, any information on the subject would be of much service.

CUTTING DOWN PAMPAS GRASS (E. A. P.).—We find it best not to cut away the decayed grass until spring, as it acts as a protection to the crown; but after frosts are past it can serve no good purpose, and is unsightly if left; it should, therefore, be removed after fresh growth has commenced. The price of "The Cottage Gardener's Dictionary" is 5s. 8d. post free from the office of this Journal.

GROWING TOBACCO (J. H. M. R.).—It is not illegal to grow Tobacco for your own use.

TREE ONION.—Mr. G. H. Archer, Essex Street, South Higham, Norwich, wishes to know where he can obtain some bulbs of this Onion.

CAMELLIA LEAVES BROWNED (W. F.).—The leaf scut has been browned by allowing water to stand upon the edges, and the sun shining on it in that state causes the mischief. The plants, we should say, are kept in a cold damp house, and air given seldom. We hope that you do not syringe them at this season, for that will cause every leaf to turn brown at the edges. Give more air; and if you syringe at all let it be in the afternoon, and let the leaves be dry before the sun shine upon them in the morning.

RAISING RHODODENDRONS FROM SEED (P. B.).—Procure some sweet sandy peat and break it fine, and three-parts fill the pans with it in an unsifted state, first draining them well. Sifted soil should then be put on the rough, and the surface having been levelled, sow the seed and cover with fine soil. Place in a cold frame, keep just moist, and let the moisture be regular. If you sow in a frame, place a good layer of rough cinders at the bottom, and on this 6 inches of turfy sandy peat, and the growth of moss is due to keeping the seedlings or the soil too wet; giving more air and keeping the soil moist, but not wet, will prevent the growth of moss. Unless you sow very thickly, which is not desirable, the growth of moss will not interfere with the seedlings until they are fit to transplant.

RASPBERRY SUPPORTS (C. Repton).—The best of all modes of supporting Raspberry canes is by iron espaliers 4 feet in height, inch-square iron supports at each end, and properly stayed with iron stays. The uprights should be 1 inch wide, a quarter of an inch thick, and pierced with holes to admit wire two-eighths of an inch in diameter. There ought to be four wires, the first at 1 foot from the ground, and the others 1 foot apart, and all should be strained tight. These espaliers should run north and south, and be 6 feet apart, and the Raspberries should be planted 2½ feet from each other. Train the canes from 6 to 9 inches apart. The iron hoops mentioned in "The Cottage Gardener's Dictionary" are good, and so are wooden stakes and hoops. They are quite as good, as regards the growth of the Raspberries, as those of iron, but not so durable and neat.

REMOVING STANDARD ROSES (Idem).—Roses may still be removed; but they will not bloom so well as if transplanted at an earlier season. So far as safety goes they may be removed up to May, and even in that month, watering well at planting and during dry weather afterwards.

NERIUM OLEANDER LEAF INFESTED WITH BROWN SCALE (A. Dull Fellow).—The leaf scut was covered on the upper surface with a black fungus, caused by the "flat insect" on the under side of the leaf secreting a fluid which falls upon the leaf, and is familiarly known as honeydew. This substance dries, and on it is produced the black fungus scut. It does not injure the leaves to any serious extent, beyond hindering their powers of inhaling and exhaling. Neriums have a peculiarly thick epidermis, and so have Oranges, which are also subject to this species of scale insect and consequent black fungus. The insect is known to gardeners as the Orange scale. To free the leaves of it, they should be washed with a solution of soft soap at the rate of 8 ozs. to the gallon of water. The plant first of all should be syringed with water at a temperature of 140°, which is not too high if syringed on the plant; but if the latter be immersed the water must be at 120°, and the plant should be kept in the water one minute. The leaves are to be washed on both sides with a sponge, pressing whilst washing them, so as to dislodge the insect and remove the black fungus. After the leaves have been washed on both sides they should be allowed to dry, and then the plants should be syringed with water at 140°, laying the pots on their sides so that the hot water may not wet the soil. The insects near the midrib may be dislodged by employing a pointed stick. A good washing with soft soap will generally keep the insect under, but repeated washings are necessary to keep plants subject to it clean.

FLOWER GARDEN (J. B. L.).—We think your proposed planting will do very well. Next season, instead of cross-planting, it might be balanced. We cannot say much for the plan, as the large lumpy figures will drown the long narrow ones; but we have no hesitation in saying, that of the two we would prefer the plan being laid out on gravel rather than grass.

PRIMULAS (T. M. Shuttleworth).—Your Primulas, judging from the single flowers, appear to be very good, the high-coloured ones especially so. If the plants are of dwarf habit and produce bristly trusses, they must be very ornamental. Hundreds of seedlings are yearly raised of equal merit, in fact, seed saved from well-selected plants is almost certain to produce promising seedlings.

APPLES ON PEAR STICKS (*Esquiers*). Apple seeds will take on Pear stocks, if a good wall for a few years, but they are not bushy.

TRANSPLANTING HOLLIES (*Holly*). Your Hollies, 3 to 4 ft. high, may be safely removed, only by a master gardener, and carefully, being particular to preserve as many of the fibrous roots as possible. Now is a good time to transplant Hollies; give a good watering after removal, and afterwards during dry weather. At the middle of May you should cut-in the trees considerably, if it is not material whether you preserve the small shoots or cut-in to the thickness of the wrist, for fresh shoots will be produced as well from old as from new wood. If, after transplanting, you do not cut them in before new growths are made, we do not think it safe to remove large Hollies at any season; but if the heads are reduced, so as to correspond with the diminution of roots, consequent on removal, we find that not one in ten dies, and those which survive become very nice trees in a year or two, care being taken to water them in dry weather. Prunt makes a very good green hedge, and one that flowers with us rather freely; but we are unable to say whether best made up use of the flowers.

BRIDS FOR "CRANSTON HORSES." Mr. W. W. Harvey, of Birmingham, fixed me a most complete and effective set to my range of 15 yards long last year, and they have already saved the rest in men's time, to say nothing of preserving plants in flower, as the plan adopted gives perfect command over sun without interfering with the circulation of air. A CONSTANT SUBSCRIBER.

LAWN OVERGROWN WITH DAISIES (*Daisy Pest*). We advise you to set to work some woman or boy, with a man to superintend. Let them cut off the Daisies by the root with an old knife. When this is done, cover the surface with from a quarter to half an inch deep of soil and well-rotted manure, mixed together in equal quantities. Spread this compost equally all over, after having gone over the lawn with an iron rake, drawing the latter backward and forward. As soon afterwards as there is a prospect of rain, sow, in mixture, for one acre *Festuca draisensis*, 4 lbs.; *Festuca tenuifolia*, 14 lb.; *Poa nemoralis*, 14 lb. (if shaded by trees a pound more); *Cynodorus cristatus*, 3 lbs.; *Trifolium repens*, 3 lbs.; and *Trifolium minus*, 2 lbs., and if the ground is liable to burn the grass in summer, add 1 lb. of *Lolium corniculatus*. Sow on a dry day, rake over the ground lightly with a wooden rake, and roll well the same day or before the seeds have germinated, taking care that the ground be dry. After sowing let the lawn alone for a month, and then mow. Roll well throughout the summer, and go over the lawn with a spade and grub up the Daisies by the root. By pursuing this treatment we have known a lawn in which Daisies and Plantains were very plentiful, become a good turf.

GERANIUM CUTTINGS DYING (*S. E. R.*).—The rooted and evidently autumn-struck Germanium cuttings sent have rotted at the surface of the soil from being kept too wet at the surface, and from the soil being much too rich. Such an occurrence is not uncommon. Your best remedy will be to repot them, or rather pot them off singly at once, using a compost of good, sweet, turfy, yellow loam. One of those sent was not in the least injured. Do not water more than is sufficient to prevent the leaves flagging from the time the cuttings are put in till they are growing freely in spring, and use a rather poor, sandy, light soil.

GUANO FOR ROSE TREES (*S. E. C.*).—You may, during the first showery weather in this month, measure a circle of 2 or 3 feet from the stem, and sprinkle over that area 3 or 4 ceps. of Purbeck guano; 1 oz. is sufficient for a circle 2 feet in diameter—that is, 1 foot from the stem all round, and give 1 oz. more for every additional foot. Another application during the first moist weather in July will be all that is required, liberal supplies of water being given during dry weather.

NEAPOLITAN VIOLETS FADING (*Idem*).—From the condition in which your plants are in we think their failure is due to their not being planted in sweet well-aired soil, that the soil has been imperfectly drained in the first instance, and afterwards kept much too wet, and that the frame has been kept too close; hence they damp off.

DESTROYING MOSS ON A LAWN (*H. H. W.*).—Under this heading at page 247, for the ground should be "dug" at the time of sowing, read "dry," &c.

GLADIOLUS GANDAVENSIS VARIETIES PLANTING (*O. G.*).—In your cold damp climate it would be well to defer planting until towards the end of April, as they will then be more likely to avoid the cold rains, and wet cold state of the soil from the rain and snow. They will sustain no injury if kept in the cold frame until the end of April, only give them plenty of air.

FUMIGATING ORCHARDS—OR TREES IN BLOSSOM (*H. R.*).—You may safely fill the house with the smoke of tobacco paper of good quality, only be careful to have the rest of the house dry at the time.

SULPHUR AND SMOKE FOR DESTROYING THE SPIDER AND GREEN FLY (*Idem*). You may dust the leaves and young shoots with the sulphur and snuff mixed, only the foliage must be dry when the snuff is dusted over the young shoots, or, if wet, the snuff will be converted into tobacco water, and this if too strong will injure the tender shoots. The sulphur will not injure the leaves or young shoots in the least, but it will not kill red spider by being brought into contact with the insect; it is the fumes that are destructive to it. A weak solution of soft soap is the best of all remedies, well certified for red spider; and for Peaches, whilst the shoots are young, it should not be stronger than 1 oz. to the gallon of water; but after the leaves have attained their full size a good spraying of soft soap solution at the rate of 2 ozs. to the gallon of boiling water, allowed to stand until cool before use, will mostly keep the leaves free, and clear them if necessary, of red spider. The safest and most certain means of preventing red spider is to proceed against it with its natural enemy—water, syringing the plants or trees subject to it freely.

CUTTING-IN ORANGE TREES (*Idem*). Orange trees may safely be cut in to the old wood; but it is by far the safest plan to thin out the old wood, leaving the best-situated of the young fresh growths of preceding years. From the thinning out of the old wood more light and air will be admitted, and those left will grow the more vigorously for it. If you could place them in a vinery at work after cutting in, or in a house having a temperature of 55 at night, and which is kept moist, they would rush more freely and freely. Keep them in the same house until the growths have been made, when a lighter and more airy structure will be preferable. If you cut them in to the old wood, plunging the pots in a bath of 70 will keep the trees to break; withdraw them from the bath by degrees after they have broken well; maintain a temperature of 55 at night, and a rather close moist atmosphere; and syringe overhead twice a day.

WILD FLOWERS OF GREAT BRITAIN (*J. C. Moore*).—The work is still in course of publication. The 6th Number was published on the 1st inst. Your bookseller or his agent is to blame. You can have the seven Numbers free by post from our office, if you enclose with your address the amount in post-office stamps and four additional for postage.

POTTING HEATHS, CAMELLIAS, AND AZALEAS (*S. E. Blake*).—The most suitable time to pot Heathis in spring; March or the beginning of April is a good time, and potting may be continued up to July. Camellias and Azaleas are best potted from a fortnight to three weeks after blooming, the plants being placed in heat and a more humid atmosphere, especially if they have been cut in; in which case they should not be potted until the new growths are somewhat advanced, or the promise of new growth is apparent. They are then to be potted, and kept close and shaded for a few days.

AZALEA INFESTED WITH THRIPS (*Robert Seott*).—The bud sent was worse infested with thrips than any which we had previously seen. Your remedy, if the plant is not beyond recovery, will be to fumigate with tobacco when the leaves are dry on two consecutive evenings, filling the house so that a plant cannot be seen from the outside. After the second smoking syringe the plants morning and evening, and this daily until the growths are made and the flower-buds set or formed. Should ever find a small black or white insect on the under side of the leaves, fill the house with tobacco smoke the first calm evening afterwards, being careful to have the foliage dry.

MOSS ROSES PEGGED DOWN (*S. J. Cook*).—Having pegged down the shoots repeatedly until the bed is too full, you may now, to make room for new shoots, thin out the weak old shoots after blooming, pegging down the best of the new in their place.

REMOVING MULCHING FROM STANDARD ROSES (*Idem*).—You may remove the mulching now, forking or pointing in the shortest of it, but not forking so deeply as to disturb the roots. The applications of guano water proposed will answer if not given in too powerful doses. The planting of a small climber to cover the stem is a bad practice, interfering with the well-doing of the Roses.

NAMES OF PLANTS *Old S. Barber*.—1, *Hyppium undulatum*; 2, *Bryum cuspidatum*; 3, *Bryum punctatum*. (*New Fossils*).—Apparently a cone of *Cupressus sempervirens*. *H. Sedgley*.—We do not recognise the leaf sent. (*E. E. H.*). *Habrothamnus ciezans*, *Pellaea foliata*, (*D. S.*).—*Deniza gracilis*, *Halimolobos*; the bit of Fern sent is insufficient for determination.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 31st.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

MARKING FOWLS

In your answer to "CHATEAU VALLON" in your Number of March 20th, he was told how to mark his fowls in the web of

the wing, either by a hot iron or a coloured thread tied in. "CHATEAU VALLON" may mark his fowls quite distinctly enough to swear to them if stolen, or to recognise them if strayed, by nicking the edge of any of the toe-nails, always marking the same nail in the same manner, and on the same side. The importance of marking fowls was made very clear to me this winter, when a person claimed a Silver-pencilled cockerel of

mine on his way home from a walk. I thus was able to swear before the magistrate to the fowl, owing to my mark, when but for that I might not have been able to have asserted my claim to my own property. It is also useful to mark birds previously to their being sent for exhibition, as sometimes birds have been accidentally substituted for others; and though you may be quite sure in your own mind that the bird returned in the stead of your own is not yours, I do not think any one could swear to a bird without a mark. I have been told that Game fowls are nicked in the eyelids, or when dubbed; but not having been a breeder of Game poultry, I cannot speak from experience. Another advantage of nicking the nail is that you can feel your mark in the dark if necessary. Of course my man knows my mark, which never varies; and I can thus substantiate my own assertion.—R. C. R.

SOUTHERN POULTRY SHOWS.

I HAVE been waiting anxiously every week to see if any of your many readers and writers would propose as a fit place for a southern poultry show my native town, Bristol, and I am glad to see the right man to do so has mentioned it in your Number of March 20th. It has been my idea for sometime, but I did not mention it. I will most willingly work with all my heart in getting it up if some, only, of the breeders will give me hopes of their support, and propose a time which would not clash with many other shows.—S. LANG, JUN., *Redland, Bristol.*

WHITE-RUMPED DRAGON PIGEONS.

I MUST apologise for again troubling you with a reply to a letter in your Journal of the 20th of March, signed "A DRAGON BREEDER." As I before stated in your paper of the 27th of February, the signature "John Percival" to my letter of the 19th of December was an error of the printer. It is not because your correspondent calculates that three-fourths of the Blue Pigeons in existence are white-rumped that, therefore, the white rump is correct; it only goes to show the difficulty in breeding to perfection, and the scarcity of the purer and more valuable strain—I mean those with the blue rump.

If your correspondent is not thankful for my having enlightened him as to what is correct, I can only say he ought to be. He very wisely withholds his name and the names of the competent judges, as he terms them, whose opinions, he says, he has sought; the publication of which would only result in their opinions being matter for ridicule by all really competent judges in the fancy. A Dragon breeder your correspondent may be, but certainly not a Dragon fancier; hence his entire ignorance of the properties the bird should possess.

I still maintain that the white rump is a glaring defect, and that birds so foully marked may be bought in any quantity at prices varying from 1s. 6d. to 2s. each, and no bargain, being far too dear for the table, which is certainly all they are fit for. In my opinion I am not singular.

I have for many years been a member of a society established for the cultivation and improvement of every kind of Pigeon—a society second to none, numbering amongst its members gentlemen known to be really competent judges, and I can fairly say I never heard one of them express an opinion on the properties of the Dragon but that condemned the white rump. Your correspondent states that blue-rumped birds are generally ticked with small black spots. I beg to inform him such birds are not Blues at all, but are known to the fancier as "Chequers," and that blue-rumped birds, both Dragon and Fantail, may be had quite as good in colour as those foully marked with the white rump. I again say that the defect is quite as glaring in the Blue Owl as in the Dragon. I have some beautiful powder-blue Owls blue-rumped: were they the reverse I would not give them loft-room.

I am quite willing to refer the matter to Mr. Esquilant, as suggested in your paper, and, indeed, to a dozen other gentlemen, if need be, in support of my views, and I feel satisfied their opinion will at once convict your correspondent of the attempt to decide on that of which he is not competent to judge.

I find, also, in your impression of the 20th ult. a letter signed "WILTSHIRE RECTOR." That gentleman's view of the matter is, that as white-rumped birds recently took a first prize at Birmingham the feathering cannot amount to a disqualification. This, however, is no criterion, as the award in the Dragon class

was ridiculed by many Dragon fanciers, and that it was not the only blunder committed at the late Birmingham Show. Whether from want of knowledge on the part of the Judges, or the hurried manner in which they had to perform their duties, I will not say, but certain it is that many of the awards gave very great dissatisfaction.—JONES PERCIVAL.

IMPROVED FRAME HIVE.

So much has been written of late years on the subject of bee-hives and boxes, and so many opinions have been put forward as to their right form of construction and requisite dimensions, that it may savour somewhat of presumption to suggest anything by way of improvement in this department of apianian science, especially when the public have been made acquainted with the almost perfect frame hives of Messrs. Langstroth and Woodbury. These two, whether for the purpose of experiment, or for obtaining the largest quantity of honey, are far in advance of any others which have come under my notice—the former, as described in his interesting and exhaustive work on the honey-bee; the other as well known in the perfect specimens which are sent out in such numbers from the manufactory of the Messrs. Neighbour, in London—and what I now venture to submit as an improvement upon these, is a slight modification of the bar at the top of the frame, which, I think, will be found greatly to facilitate the removal from the hive.

Both in the Langstroth and Woodbury hives it is necessary to thrust the finger and thumb into the hive (when the top has been taken off), in order to lift any single frame requiring to be either examined or removed; but this is not always so easy a matter when the two ends of the top bar have been well glued down by the bees, and the fact of these ends resting upon a ledge or rabbet, prevents a backward or forward movement for breaking the seal before lifting the frame. It therefore occurred to me, that it would be attended with advantage to elongate the top bar of the frame, and carry it right through the front and back of the hive, allowing it to extend beyond the outside about half an inch, so as enable the operator to lay hold of it firmly with thumb and finger outside, instead of inside the hive. Accordingly I constructed all my hives on this plan; and, having now tried it with considerable success for about four years, I have been persuaded to submit it to my apianian friends through the medium of these columns, and thus afford them an opportunity of testing it when they are making or ordering any new frame hives.

The dimensions of my frames vary considerably both from those of Langstroth and Woodbury, but this is a matter of little importance, as my plan of elongating the top bar may be applied to any size of frame.

DIMENSIONS OF HIVE.—Depth, always 10 inches; length, from front to back, always 15½ inches; width, varies according to number of bars, eight-bar hive, 13½ inches; size of frame may be reckoned from the length and depth of the hive, allowing a clear space of three-eighths of an inch at top, bottom, and sides; top bar 1½ inch wide.

The size of my boxes is also different from any other that I know of, being always of the same depth—viz., 10 inches, but, of course, varying in width, as constructed to contain from four to ten frames, as the locality in which I reside is by no means favourable for bee-keeping; the woods of east Kent being about the same in character as the woods in other parts of the kingdom—viz., high, windy, and open. My boxes are usually made with eight frames, but I must, in justice, add, that the greatest yield of honey I have ever obtained was from

a ten-frame hive, in a snper of last year, and which weighed 38½ lbs. nett, realising in the market 2s. per lb.

Should any of our apianian readers be desirous of obtaining a specimen of my hive, they may do so by application to Mr. W. Pettitt, the practised apianian and skilful hive-maker of Snargate Street, Dover. I may also add, that Mr. Pettitt has invented a metallic bar holder for the tops of the frames to rest in, at the back and front of my hives, but which may be applied to any other frame hive for the same purpose.—**SHEERT-IN-THE-WOLD.**

CHANGING A NUTT'S TO A BAR-HIVE.

HAVING been much interested by the account published at page 234, in THE JOURNAL OF HORTICULTURE, containing suggestions for converting a Nutt's hive into a bar-frame hive, it may be useful to "A NEW BEGINNER," as well as to others, who, like myself, are advocates of the bar system, if I inform them of some of my "doings" at alteration.

I have several sets of "Pettitt's collateral-hives," which consist of two separate boxes. I saw away so much of the end of each of these boxes, that on uniting the sawed edges I have one box 21½ inches long internally, giving room for thirteen frames, each 1½ inch wide. I now take a pair of Pettitt's patent metallic bar-holders, which I purchased from him at Dover in the winter. These I screw on to the top edges of the boxes, thus connecting them at top. The bottom edges I connect by screwing strips of deal 1 inch square all round. I have thus a hive 21½ inches from side to side, 11½ inches from back to front, and 10 inches deep, ready to receive thirteen bar-frames. I obtained the thirteen frames from Mr. Pettitt, with one "dividing" frame, which is a panel fitting the inside of the hive, and which enables me to contract or enlarge the hive at pleasure. The top bars of these frames are of sufficient length to project about half an inch through the back and front of the hive. This projection gives much greater power and facility in loosening and removing the frames from the hive when required. Mr. Pettitt has also, I found, adapted metallic bar-rests for the Woodbury and Langstroth hives, and I was so much pleased with his ingenious contrivance, that I purchased a few pairs, and intend to apply them to my hives forthwith.—**F. C. V., Weybridge.**

LIGURIAN BEES IN THE HOLY LAND.

OLIVE oil, goats' hair, and tobacco, seem to be the principal produce of the district; the latter being exported in some quantities by way of Acre to Egypt. Bee-keeping, also, is not an unimportant item of industry, and every house possesses a pile of bee-hives in its yard. Though similar in its habits, the hive bee of Palestine is a different species from our own. We never found *Apis mellifica*, L., our domestic species, in the country, though it very possibly occurs in the north; but the common Holy Land insect, *Apis ligustica*, is amazingly abundant, both in hives, in rocks, and in old hollow trees. It is smaller than our bee, with brighter yellow bands on the thorax and abdomen, which is rather wasp-like in shape, and with very long antennae. In its habits, and especially in the immense population of neuters in each community, and in the drones cast forth in autumn, it resembles the other species. Its sting also is quite as sharp. The hives are very simple, consisting of large tubes of sun-dried mud, like gas-pipes, about 4 feet long, and closed with mud at each end, leaving only an aperture in the centre large enough for two or three bees to pass at a time. The insects appear to frequent both doors equally. The tubes are laid in rows horizontally, and piled in a pyramid. I counted one of these colonies, consisting of seventy-eight tubes, each a distinct hive. Coolness being the great object, the whole is thickly plastered over with mud, and covered with boughs, while a branch is stuck in the ground at each end, to assist the bees in alighting. At first, we took these singular structures for ovens or hen-houses. The barbarous practice of destroying the swarms for their honey is unknown. When the hives are full, the clay is removed from the ends of the pipes, and the honey extracted with an iron hook; those pieces of comb which contain young bees being carefully replaced, and the hives then closed up again.

Everywhere during our journey we found honey was always to be purchased; and it is used by the natives for many culinary purposes, and especially for the preparation of sweet cakes. It has the delicate aromatic flavour of the thyme-scented honey of Hybla or Hymethus. But however extensive are the bee

colonies of the villages, the number of wild bees of the same species is far greater. The innumerable fissures and clefts of the limestone rocks, which everywhere flank the valleys, afford in their recesses secure shelter for any number of swarms; and many of the Bedouins, particularly in the wilderness of Judea, obtain their subsistence by bee hunting, bringing into Jerusalem jars of that wild honey on which John the Baptist fed in the wilderness; and which Jonathan had long before unwittingly tasted, when the comb had dropped on the ground from the hollow tree in which it was suspended. The visitor to the Wady Kurn, when he sees the busy multitudes of bees about its cliffs, cannot but recall to mind the promise, "With honey out of the stony rock would I have satisfied thee." There is no epithet of the Land of Promise more true to the letter, even to the present day, than this, that it was "a land flowing with milk and honey."—(TRISTRAM'S "Journal of Travels in Palestine.")

SHEFFIELD POULTRY SHOW.—As will be seen by reference to our advertising columns, it is again determined to hold a poultry show at Sheffield, under the management of a few of the most spirited poultry breeders. It has the promised patronage of the Mayor and most of the leading families of the district. The prizes in the aggregate amount to about £170. The poultry premiums are £2, £1, and 10s.; for Pigeons, 15s., 10s., and 5s.; the Rabbits having prizes of £1 and 10s. allotted them. The show will be held in the Brownhill Cricket Grounds, near the Botanic Gardens—a site undoubtedly the best suited for the purposes of such a meeting of any in the neighbourhood of Sheffield; and it will take place on the 19th, 21st, and 22nd of May next. As we are informed the Committee intend personally to carry out all arrangements, there can be little doubt the meeting will be well supported.

OUR LETTER BOX.

FOWLS WITH SWOLLEN FEET (R. F. J.).—Appearances such as you mention are often caused by improper flooring to poultry-houses—wood, brick, asphaltum, stone, will all cause it. It is not natural for a fowl to be always standing on a hard surface; the toes are thereby spread out, the ball of the foot comes to bear the whole weight, and the nails take no hold of the ground. Loose earth and gravel are proper flooring, but none is good where the impress of the foot is not left wherever it is put down.

ULCERATED EYE AND HEAD IN FOWLS (W. G. B.).—You would enable us to answer your question more easily, and probably more usefully to yourself, if you told us what breed the fowls are, and whether all the same; because as some are perfectly well, while others die, it is possible that among the fifteen you have those which thrive in confinement, and those that require a run. Put in your run two or three cartloads of road grit, the scrapings or cuttings of the roadside; do not spread them over the place, but let them form two conical-shaped heaps as high as possible. It will be the fowls' pleasure to scatter them in searching for grass, &c. Indian meal and potato-peelings are not good feeding, and fowls thrive in spite of it, rather than because of it. Alter your dietary scale: feed in the morning on meal, mixed with water; at midday with whole corn; in the afternoon with meal. Give Indian corn twice a week for a change, bread and ale in very damp and cold weather. Animal food is not necessary. Put some camphor in their water. Give the sweepings of your table, and the kitchen scrapings. If in spite of all this their faces still swell, wash with cold water and vinegar. We believe that if you follow our directions you will do well with your poultry.

WHITE FEATHERS IN SPANISH FOWLS (C. S. B.).—It is not uncommon for Spanish fowls to throw white feathers. It is most uncommon for such to be sold, and we have not heard of it before. If when sold they had no appearance of white the seller could not foresee it; but if there were already spots, every breeder of Spanish is well aware they always increase, and such birds should not be sent. They would be laughed at at a show. Mr. Boyle's are very good Brahmas; so are Mr. Pigeon's, of Lymington.

DUN GAME FOWLS (R. H.).—We do not know where Dun Game fowls are to be had. There used to be some in the neighbourhood of Liverpool, but we have seen none for years. They were kept by fly-shiners for the sake of their hackles.

FOWLS PEKING OFF EACH OTHER'S FEATHERS (D. J.).—Your fowls lack something, or else they are overfed. When they take to feathers they are suffering from fever, or plethoria. In the first case, they eat all sorts of unnatural things in the hope of finding a remedy; in the second, they have an unnatural craving. Supply them with growing sods of grass, and let there be plenty of fresh mould taken up with them; let them have lime and bricklayers' rubbish in their haunts. If you have lettuce, give some to them. Fowls will stand still to be eaten by their companions.

BANTAMS WITH COCHINS (Eboracum).—You may let them run together without fear of cross-breeding. As you object to dubbing, you had better keep your other sets, Black Bantams. We know nothing about the book you mention, and have no dependence upon its contents, except so far as borrowed from good authorities.

POULTRY FOOD, &c. (Braham).—By "crushed" we mean flattened by being passed through a mill invented for the purpose. Your hen's egg-organs were inflamed, and well they might, so far as you say—*ay she was*. She died of oedema in consequence.

HENS (R. H. and J.).—For cheapness and simplicity we advise you to use Lyons'. If you write to Messrs. Neighbour & Son, Regent Street, London, they will send you a list of prices.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 56.5°; and its night temperature 36.1°. The greatest heat was 73°, on the 14th, 1852; and the lowest cold 20°, on the 10th, 1860, and 16th, 1847. The greatest fall of rain was 0.56 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

GARDENING PROSPECTS IN QUEENSLAND.

AR away over a wide waste of waters there is a goodly land, the coast of which is circled by the South Pacific Ocean. It is a land of rivers and of woods, of large sweeps of down offering rich pasturage to a thousand herds—a land, if not exactly “flowing with milk and honey,” yet answering so promptly and so liberally to the labourer’s call, that I think a little intelligence about it, coming for the most part from working men themselves, may be alike interesting and useful. It is a land where, I am told, the settlers live at first in tents, with “no rent to pay, nor fixing to buy, nor poor’s rates, nor any other rates; no dog tax nor shooting license;—where we live, in fact, just like we read of in the Bible.”

After a while the tent is transformed into a “humpy,” or house built of logs of wood, where “I sit,” says an emigrant, “sixteen thousand miles away from the old city, with a cloudless sky above me, the deliciously soft and balmy breeze of a Queensland spring morning whispering through the Gums and Cedars in the valley below, and stealing in at my open window, the magnificent river (Brisbane) creeping slowly round the foot of the hills on its way to the sea, and all around giving promise of competence, if not wealth, to a man who has the skill and the heart to work hard for a few years, live economically, and keep both his eyes wide open.”

The cost of building the humpy would be but a few shillings, “as it could be built of bark, and the black fellows would bring in from the forest sufficient to build a house for a few figs of tobacco, which at the most would only cost four or five shillings; or if built of logs, and you could not split the wood yourself, the rail-splitters would bring you a sufficient number of logs to build a house for a pound or thirty shillings.”

Were I to describe the furniture of this very primitive dwelling it might startle all ideas of comfort from an Englishman’s mind in England. “I am my own cabinet-maker,” says another emigrant to me, “and you would be surprised to see how handy I have become, and what lovely articles of furniture I can knock up out of an old box. Everything comes in—bits of tin from old packages—old calicoes and cloth—in short, any and every thing.”

The humpy will probably be situated on a “bit of land of my own,” the produce of the “land order” given to every emigrant who pays the £18 for his own passage; or it may be acquired after this fashion:—“My father,” writes a young settler, “has a piece of land—not a very large piece to be sure, but it is sufficient to build a house upon, and also to grow garden stuff to serve him all the year

round. It is not quite three-quarters of an acre. The price was to be £6, with £1 for the transfer. Father was to work the price out.”

“The “bit of land of my own” may, if near a town, be turned to most profitable account as a market garden, and it will be found to produce a little more than the Potatoes, Cabbage, Peas, Asparagus, &c., of England, and with infinitely less trouble. “There is a heap of rubbish,” writes one of my friends, “by the side of the footpath. Out of five Pine-Apple tops which seem to have been thrown down promiscuously, one has taken root, and if left alone will bear fruit. Here are Tobacco plants springing up too, Water Melons, Pumpkins, and a number of plants, only seen in forcing-houses in England, all starting into vigorous life from this heap of rubbish.”

But there is more than the produce of the rubbish heap, or every man would be his own rubbish-gardener, and market-gardeners have little custom. “It is now (September) spring with us,” says the same friend; “the Peach trees, with which every garden hereabouts seems crowded, are all covered with blossom so thickly that you cannot see the wood of the branches. The Rose trees, that through the winter have only had here and there a bloom upon them, are now bursting out on every spray.” Still, Peaches that are ready to drop into every open mouth can hardly pay for the trouble of growing; nor would they and the rubbish heap combined satisfy the demands of cooks—a class noted for being a little uppish, particularly in a land where “our Clara,” a girl of about twelve, “is getting £18 a-year;” but there are many vegetables as well as fruits.

“We get plenty of Bananas,” writes a market gardener’s assistant to me, “and Sweet Potatoes to eat raw; they taste a good deal like the pig or ground nuts. We also get very good Cabbages, and the same kind of Potatoes as we had at home. My master and I have planted a large piece of land with Cotton [the Queensland cotton shown at the Exhibition of 1862 was pronounced fine, evenly grown, and good], and he is growing acres of Arrow-root. The plants look like great Onions, only they have very broad leaves. We have also planted Indian Corn and Lucern. We are now (October), mowing the Oats for the cattle, as the ear does not fill. We grow Sugar, Oranges, Lemons, Peaches, Pine Apples, Locusts [Ceratonia siliqua], Guavas, Tea, and Tobacco; also Carrots, Turnips, Radishes, Lettuces, Onions, and Cucumbers, with many others the names of which I do not know.” That there is some garden produce which is not easily found in Queensland may be learned from a request made by the same writer to his brother, about to join him in Queensland. “Please bring,” he says, “roots of Thyme, Sage, Rue, Rhubarb, Currants, Gooseberries, Horseradish, Leeks, Marigolds, and Box, in air-tight boxes; bring also some hips, haws, acorns, Chest-nuts, and Willows, also all sorts of English flower seeds.” The writer was in 1862 a weaver in England; and during a great depression in the trade he, with several brothers and sisters, together with his parents, emigrated to Queensland, where he learned a gardener’s profession to such good purpose, that in 1865 I hear “W—, A—, and D— have taken a farm to work it as a market garden,

and father and I— have been fencing and clearing it, while W— and D— remain at service, so as to have the means of purchasing stores until the first crop come in. The farm is very pleasantly situated on the banks of the river Brisbane. I went out into the forest for a day's shooting about a fortnight ago (September), and towards night found myself rather unexpectedly at the fence, when I got over and looked at the farm for the first time. They had cleared about four acres, and a very promising crop of Maize was just peeping through the ground among the old tree stumps. About three more acres had been cut down, and was just being burnt off. The great amount of iron bark trees, which had been prostrate a few weeks before, were flaring up to the sky, and the flames, fanned by a strong evening breeze, were roaring and crackling grandly."

"And while the crops are growing and the wages coming in, there is any quantity of fish for the catching, any quantity of wallabies. I wish I knew what these were. Kangaroos, opossums, flying squirrels, flying foxes, ducks, turkeys, parrots, and emus for the shooting; and as to the wood to burn, there is more than enough to supply all the rest of the world, for the cutting, anywhere in the bush." The labourer in the bush, will by no means lack company, for he will have "snakes and lizards; frogs green, white, and blue; a great variety of butterflies; and in the death's-head moth is very common; parrots by thousands, blue, green, yellow, red, and grey; and laughing jackasses, and finally not confined to Queensland. One kind of bird, indeed, is more like an ungreased wheel than when it is drawn over. Another is continually saying "Six o'clock, Jack!" "Six o'clock, Jack!" Another creaks out as if from down a long slope, "More pork! More pork!" Another is continually going "W-w-r-r-r-r-r-r!" Another says, "Whip-poo, Will!" one would hope interperatively. There is one that is all the while, when, "This little fellow has a beautiful rich black body coat, his head and tail being of a bright red. They are exceedingly tame, and will come close up to you. They have a sweet, soft, little song, something like the wren at home." Besides these there are the pelican, heron, stork, common crow, owl, wild turkey; and, above all, there is a little fly called a mosquito, that keeps you awake at night, so that you may hear the cuckoo singing." And when the tired labourer leaves the bush for his humpy, there beneath its eaves he may find "the swallow building her nest just as she does in the old country; only our swallows, have little russet-coloured heads, and brown and white-spotted backs and wings."

Yes, I am afraid that "old country," with all its varied associations and memories, now gleaming out of the dim past, now shining with the brilliant light of yesterday, rises up for ever and anon before the emigrant, dimming his eyes with tears, while his strong right hand bows away at the giant trees with "vine as thick as my arm, like great ropes, growing upright up from the ground, clinging to the high branches, while hanging parasitic plants trail all over them." Nor is it the earth alone which reminds him of vanished times; when his eyes glance upwards in reverent questionings of a still fairer brighter home, the old clinging memories are there also. "I thought," writes one, "when I lost sight of the North Star, and afterwards of the last star in the tail of dear old family Cass Major, that I should have to make acquaintance with new constellations of stars altogether, and lose all the old ones. And now, of what the others might be by the Southern Cross, I made up my mind not to like them. Imagine my plea-
sure, and surprise, then, when I found that two or three of the constellations had not deserted me. Orion and the Bull still lay down upon me, but I feel somewhat sorry to see them so altered. They gradually changed their position, as we came from the Cape of Good Hope; and now poor Betelgeuse is set upon his back, and Orion comes up heels first. I cannot but feel that such treatment of old friends is unwarrantable, and only to be lamented because one cannot prevent it. However, I would sooner see them heels uppermost than not see them at all, and I therefore take it very kind of them to come out and see me in the night after night, especially when they have to appear under such disadvantages."

How terrible this home sickness is they only who have felt it can tell. The longing that comes to see old familiar places, to hear old familiar voices, with that strangest yearning of all in death—to have our homes laid amidst the graves of our kindred—all these thoughts and longings are unavoidable enemies that the dweller in Queensland has to do a sore battle with; but these foes are not so hard to deal with as those that lurk behind an empty cupboard, or turn a brave man into a coward at the sight of a tax-gatherer.

The drawbacks to Queensland are floods and drought, yet these are partial; and by the March mail of this present year an emigrant writes, "The first part of this present summer has been hotter than usual, and we are still suffering from drought, but nothing to be alarmed about at present; indeed in some respects the season has been a most favourable one. The vineyards in the Brisbane district were never known to look so well. I was over one at Kedron Brook the other day, from which the proprietor is gathering four tons of Grapes per acre. The Sugar and Cotton crops are both looking remarkably well."

Of the beautiful Ferns of Queensland and of the few plants sent to me I have no space to write; but they deserve special notice and a future paper to themselves should more information be sent to me.—*DELONIA.*

HOW TO INTRODUCE PLANTS OF THE MANGOSTEEN (*GALFINIA MANGOSTANA*, L.)

SEVERAL articles having lately appeared in *THE JOURNAL OF HORTICULTURE*, giving an account of the free propagation from cuttings and fruiting of the Mangosteen, it may, therefore, be considered quite unnecessary for any person to go to the expense of importing plants from their native country. During my long experience I have seen but few plants of it. Some years ago there was a very fine plant at Kew, and the only place at which one has been known to fruit was at Sion House gardens. It is, therefore, not without a little surprise that I have seen "J. H.'s" account of his plants, how he strikes them from cuttings, and fruits them.

Now, without knowing anything of "J. H.," or having even seen his plants, I, nevertheless, unhesitatingly venture to say that the plant he is calling Mangosteen is not that plant, nor even belongs to the family of Guttifera; and I will be safe in saying that no plants of Mangosteen have yet been obtained from cuttings. Cuttings will callus and root, but refuse to grow upwards. Indeed, the whole of the Guttifera, more especially the large-leaved species, do not propagate from cuttings. A few weeks ago half a dozen plants said to be Mangosteen were advertised for sale, as having come from Singapore. Coming from that country it is reasonable to believe them to be the true plants; if so, they are, therefore, with the Sion House plant, the only representatives of this rare fruiting plant known to me in this country at the present time.

The many inquiries that have been made during the last twenty years at Kew for plants of the Mangosteen, have been a matter of surprise to me, seeing the facilities that are now afforded by steam navigation for the quick transport of plants from distant countries; but on account of the trans-shipment and frequent delay at Calcutta, with the hot passage through the Red Sea, considerable expense and risk attend the transmission of living plants from the East in Ward's cases. In the case of the Mangosteen, however, Ward's cases are not necessary, as will be seen by the following successful experiment. Some years ago a correspondent at Singapore was requested to send Mangosteen fruit to Kew, which he did by placing a single layer of fruit side by side in a thin wooden box, just sufficiently deep to hold the fruit with out any packing. On the box being opened the fruit looked like Apples with the skin a little shrivelled. The inside was still pulpy, and it was found that a portion of the seeds had germinated, and in a short time, without disturbing them, the others also germinated. By this method I consider Mangosteen plants may be made quite common, or, at least, sufficiently so to supply the demand. I have to remark that the success of this method depends on having only one layer of fruit in a box; two might succeed, but any great quantity together are liable to ferment and destroy the embryo.

The ill-success that has hitherto attended the growing of the Mangosteen is consequent on the too general practice of pot culture. If garden pots were scarce, if our bothouses were adapted to meet such a contingency, and if the nature of the plant were better studied, then hopes might be entertained that dishes of Mangosteens would be seen competing at the fruit exhibitions of the Royal Horticultural Society.—*J. SMITH, Lib-Curator, Royal Botanic Garden, Kew.—Park House, Kew.*

THE SEASON FAR NORTH.—We are informed that even so far north as Stormoway, Primroses and Polyanthus have been in flower since December; Willows in January; Hazel, in shel,

tered places, in February; and in exposed places Alder, Hazel, Crocuses, Snowdrops, Mahonia, all coming into flower since the 12th of March. *Daphne mezereum* is in full flower now (April 2nd), as also the pretty little blue *Scilla*.

THE RELATIVE MERITS OF THE STOCKS USED FOR THE APPLE AND PEAR.

WHEN I incidentally remarked in my article on stocks for grafting (page 215), that I had not had much experience with the Paradise stock, I did not intend to imply that I had not had any; on the contrary, my acquaintance with the Paradise stock dates back thirty-five years or more, when I perfectly remember having to cut some dead and cankered wood out of trees which ought to have been just in their prime, as others of the same age worked on the Crab were. I may add, that some unworked Paradise stocks were also at the same place and in much the same condition, the tops in many places dead, and canker eating through the thicker branches. About ten years afterwards I had also to operate upon a number of trees on the Paradise which were not so bad, the situation being more favourable, and they were younger, but they certainly were not so good as others worked on the Crab. Since then I have occasionally had to manage trees worked on the Paradise stock, but they have been less numerous than before, and those I have met with presented the same features as others which came under my eye many years ago. I legitimately inferred that the Paradise and Crab in 1866 were the same as they were in 1826, and gave my opinion accordingly: most certainly I did not give that opinion without a fair share of experience, for although I have not absolutely had under my care many trees of the kind your correspondent, "T. R.," so strongly recommends, I have seen a great many, and their appearance confirms what I have said. Tidy, neat-growing, young trees are plentiful enough, but by the time they arrive at a size capable of yielding half a dozen bushels of fruit, decay has set in; the trees are no longer healthy, and in a group may be picked out at once, as was done by a friend of mine not many days ago, when looking over an extensive orchard belonging to a third party, and such a tree he pointed out at a long distance as a Ribston, another as a Hawthornden, and on a closer inspection it was admitted by the owner that some unhealthy specimens had come from a distant nursery, and had been worked on the Paradise stock.

These facts go far to prove the superiority the Crab has over the Paradise stock when a permanent orchard is desired, but when a tree is planted to assume some fanciful shape, regardless of fruit, the dwarfier stock has its advantages; and where the soil and situation are favourable, the Paradise may even supersede the Crab for espalier and pyramid trees; but fruit obtained by these means fills the basket slowly, especially when the latter mode of training is adopted. At the same time the appearance of pyramid-trained trees is so good, and there are so many points in their favour, that I for one admire and adopt them; but the quantity of fruit thus obtained forms a very small fraction indeed of what is required for the consumption of the country, so that in advising the general adoption of the Crab stock, I am justified by the practical experience of the growers of more than nine-tenths of the Apples produced in the kingdom. So much for my own vindication of opinion, let us now see what "T. R." says in criticism.

I beg to tell "T. R." that I have seen the stain I alluded to, made by budding the purple *Cytisus* on the *Laburnum*, or I would not have stated so, and I believe such an occurrence was recorded in one of the earliest volumes of the "Transactions" of the Horticultural Society, by a gentleman having ample means of observation, as he had upwards of one hundred acres of nursery ground in full crop; and as "T. R." admits having seen a similar stain from other things, he has no right, especially under an anonymous signature, to deny its being so.

"T. R." is wrong in supposing that I meant the Pear grafted on the Quince as being only capable of producing about one-fourth of what the Pear would do. I meant exactly what I said, that I had never known an instance in which the Quince tree (as a fruit) produced more than one-fourth of what the Pear would do. Has "T. R." known it do so? He mentions an instance of one hundred bushels of Pears on one tree. Has he ever seen more than twenty-five bushels on a Quince tree? I have never seen anything like that quantity on a single tree, and I always understood the recommendation of the Quince as a stock for the Pear, to be its less luxuriant and dwarfier

habit of growth; and I find several nurserymen who propagate the Pear extensively, recommend the Quince stock for this reason, and a very good qualification too, and one for which I admire and cultivate trees on the Quince. Still I am not blind to the merits of the more free-growing stock, and where the soil and other circumstances favour it, the produce is more in quantity and better in quality. This may appear to be saying much, but if the history of the prize fruit at our great metropolitan shows be searched out, and also that of more than three-fourths of the fruit at Covent Garden, it will be found that the Pear stock has produced them. I have more than once in my life been curious in ascertaining this. I therefore see no reason to depart from the views put forth in my former article recommending both, but the Pear especially, in favourable localities.

From the little I said about the Briar and Manetti as stocks for Roses, criticism was uncalled for. I can only repeat what I have several times stated in the pages of THE JOURNAL or HORTICULTURE, that I ignore both stocks except in the case of standards, and I find other growers are doing so also.

It would have been better if "T. R." had made a comparison between the best fruits grown in Worcestershire on the Pear stock with the same grown on the Quince, rather than have taken the extreme case he has. I believe the comparison is often enough made on the tables of our fruit shows. The inference drawn from his remarks would be, that if the tree of Cheau-hay Pear had been worked on the Quince instead of the Pear, there would have been only twenty-five bushels instead of one hundred, a result by no means commendatory of the Quince.

"T. R." next goes into figures to show the advantage of having a large number of trees, and points to a plot of something less than an acre of ground having two thousand trees upon it. Now, let us follow these figures out and see what ought to be expected from an acre of ground with such an expensive crop upon it. In the first place these two thousand trees would cost the buyer, at 2s. each, just £200, and the price is only a fair and just one, such as a nurseryman who can assure the buyer that the trees are true to name ought to receive. I may add, that I paid this sum lately to a London firm for some, and I saw some from Mr. Rivers, of Sawbridgeworth, lately that were the same price. Well, then, "T. R." tells us that each tree ought to be trimmed by professional men—amateurs—and not by the "knifeman," whom he scoffs at, and the gardener who does the work with his hands. Now, how much per annum has to be placed against the account of this acre of trees? Learned men at the present day expect to be well paid, and so they ought to be, and two thousand trees are a great number to attend to; therefore, some large sum will, doubtless, be yearly expended in their management, to say nothing of the more vulgar operation of preparing the ground beforehand, and similar work afterwards. More explanation on this head is wanted, so as to let us know how much has to be added to the £200 per acre at first expended on the trees, by the employment of those well skilled in gardening, not professional gardeners.

In the same paragraph "T. R." tells us "such trees never fail to bear if their blossoms are protected;" but what an awkward qualification the latter part of this sentence is. Protecting the blossoms of two thousand trees must necessarily call into operation some costly contrivance, which a guinea a-bushel for the fruit will hardly be sufficient to pay for. Now, it would have given myself and many others more information if "T. R." had described how this protection was to be afforded, rather than told us that he had several thousands of such trees to sell. If recourse to protection has to be made through such means as our friends in Manchester, Bradford, and Nottingham can supply, a very heavy bill will soon be run up in this way, for such fabrics are not by any means cheap. Some enlightenment on this score will be very acceptable.

Now, in relation to the paying capabilities of a plantation of trees like that described by "T. R." in the paragraph alluded to, I will relate a case, which, though occurring upwards of one hundred miles from here, I was, nevertheless, well acquainted with. A gentleman retiring from business with an ample competency, built himself a house in the country, and planted and took especial pride in his garden. The situation being favourable things generally flourished with him, and being still active and enterprising, he did much of the work himself. Like many others, he planted a plot of ground with fruit trees trained in the pyramid fashion. I think he allowed somewhat more room than "T. R." speaks of, but in other respects they

were treated the same, and they looked well and bore as well as trees similarly treated generally do—that is to say, in favourable seasons like 1864 and 1865 there was plenty of fruit on Pears and Plums, while in 1864 there was scarcely any. The trees were, I believe, somewhere about eight years old or more, and had come from Mr. Rivers, of Sawbridgeworth. I believe the gentleman had received many flattering compliments from friends to whom he had given fruit in seasons when this was plentiful; such compliments the usages of society never deny, and are mistaken by some people for opinions. Well, time rolled on, and in the great uncertainty of most earthly things, our worthy gentleman was suddenly called to another world; as is not unusual in such cases, the estate was speedily offered for sale, and it being determined to make every shilling from it that could be done, the fruit was to be sold, and an eminent salesman of Covent Garden consulted with, and made fully aware of the advantages the fruit had over such as he had sent him from elsewhere. The fruit was in due time sent up; but, alas! for the dulness that “T. R.” speaks of, the buyers could not see in which way it differed from other fruit of the same kind offered to them, excepting in being somewhat smaller, and they would only give a second-rate price for it; and after deducting commission and carriage, the estate realised the sum of 17s. 3d. on the produce of about 160 trees, and that mostly for Plums. Now, these trees had been carefully attended to, looked well, and I understood had a fair crop upon them. So much for absolute, not ideal, *E. s. d.* remuneration.

“T. R.” seems fond of quoting the practice of our French neighbours; in this I cannot hold much argument with him, not having seen sufficient of their practice to warrant an opinion. Certainly I have seen some of the gardens around Paris, and those of some other towns, and that too in the height of the fruit season, and from what I saw my opinion would be that a better dessert could be obtained in Covent Garden from English-grown fruits; and taking into consideration the advantages which the climate of France affords, I think English fruit-growers may take some credit to themselves. This matter, however, deserves to be carefully considered, and the forthcoming International Horticultural Exhibition will, no doubt, throw much light on this subject.

“T. R.” alludes to my not being in the mercantile world of gardening, and not knowing much of what is taking place in it. I certainly do not propagate fruit trees for sale, and am, therefore, not liable to the imputation of puffing any particular class of tree, but as a disinterested person I wish for nothing but the truth. I am, however, far from classing the Paradise and Quince stocks amongst absurdities; on the contrary, both, more especially the latter, may be and are useful in their way, but are they of such national importance as those opposed to them? I am very much mistaken indeed if the verdict of the fruit-growing and fruit-eating public will not be a decided negative, whatever fruit-tree propagators may say to the contrary. It is not my intention to depreciate any particular mode of growing fruit, but if a certain mode present a chance of growing two good fruits instead of one, it is my duty to advise that. Let “T. R.” inquire of the great salesmen of Covent Garden whether they receive their supplies, and follow up his inquiry, and he will find that the large orchards which furnish the best fruit are all worked on the Crab stock, and his own remark of the Paradise stock being known and used in England for a century, and being still not general, is a tolerable proof that its superiority is more than questionable, excepting for growing small quantities of small or medium-sized fruit on trees from which elderly gentlemen can gather it while standing on the ground. These advantages it would be wrong to undervalue.

With respect to the Quince stock for Pears, I will go further, and admit that it is of service in more ways than the Paradise has been for Apples; but has fruit so grown ever excelled that grown on the Pear stock in size, flavour, or abundance? The test of our fruit shows and fruit markets is a better criterion to go by than the words of the sellers of young trees so worked; and if “T. R.” rebukes me for giving an opinion on the Paradise stock, the public can judge for itself whose opinion carries with it the least appearance of self-interest. Fruit-growers as a body can well afford to hear themselves called dull and slow; but few classes of men are more alive to their own interest and that of those for whom they provide than are some of the large fruit-growers in this neighbourhood. Not content with visiting other parts of the kingdom famed for good fruit, they occasionally take a tour to Belgium, the Channel Islands, and France, and observe the modes of cultivation practised there.

A very near neighbour of mine sent upwards of 1300 bushels of Plums to Covent Garden last year; but there are other still larger growers, and Apples and Pears are, of course, still more extensively grown. Growers have followed their culling long enough to know what is likely to answer best in their respective localities, and though there are but few who do not make experiments, the result arrived at is, that the situation that will grow a fruitful tree to a large size, and healthy and vigorous, is the one to plant with that fruit, and there the tree will be likely to fill both the basket and the pocket. Those who prefer distorting a tree into whatever fantastic shape the fashion of the day may dictate, be that fashion a cylinder, basin, umbrella, or cone, can accomplish their object; the tree will endure it, and the term beauty may be applied or misapplied, as the idea may be, to each or all of them. Be it observed, however, I do not mean to say that some of these forms are not beautiful, but the question arises, Is the fruit better or more plentiful? If it were so, those who grow for market would have adopted it long ago. Filberts are all pruned-in with a severity and exactness to shape and size which from long study and careful practice the growers have found is the best way to secure a crop, and the same would have been done with other fruits had a similar practice been attended with a like result.—J. Ronson.

APPLE TREES ON THE FRENCH PARADISE STOCK.

HAVING planted a number of young Apple trees from Mr. Scott's nurseries at Merriott, I have naturally felt much interest in reading the various papers relating to the Paradise stock in *THE JOURNAL OF HORTICULTURE*. It is a matter of no small interest to gardeners and others, for we are anxious to produce as quick and permanent a return as possible for the outlay we incur. In the absence of large orchards, and being confined to the kitchen gardens and strips outside, dwarf trees are unquestionably the most convenient, interfering but little with the general cropping of the garden, and of these we can plant a goodly number, making up in some measure for the produce of larger trees, which would shade the ground too much for vegetable crops. I know well the value of a good large orchard. For sixteen years I lived where there is, perhaps, one of the finest orchards in Somerset, and I have gathered as many as twelve or sixteen bushels of good marketable fruit from one tree, and there are many such trees in the same orchard.

In the autumn of 1863 I paid a visit to Mr. Scott's nurseries, and selected a number of dwarf Apple and Pear trees to plant in these gardens. Nothing could look better than the trees in the nurseries, no canker nor the least bit of moss was there to be seen on the trees, and the bark looked as though it had been polished; again in the autumn of 1864 I had some more trees from the same nursery. Our soil is a cold retentive loam, and the situation of the garden is low, cold, and damp, and early and late frosts are, perhaps, more injurious than in any part of the county of Somerset, but I am pleased to say that the trees, without exception, are doing well; and of those planted in November, 1863, most bore a fair crop of good fruit last summer, especially Cellini, Winter Hawthornden, and Northern Spy. Thus in by no means a favourable situation have trees grafted on Mr. Scott's French Paradise stocks done well, and come into bearing early, the latter an object much wished for in these days. Allow me to add a few words in favour of that beautiful Apple the Cellini. It is very handsome, and attracts the eye of every passer-by, comes into bearing early, and bears freely. Dr. Hogg says of it, “Flesh white, tender, juicy, with a fine brisk balsamic flavour and high aroma.” G. D. VALLANCE, *Gardener to Sir W. C. Medley-cott, Bart., Fen Hall.*

CULTURE OF TOBACCO.

Now is a good time to sow Tobacco seed. Any one who has a warm dry frame can raise the seedlings as well as in a hot-house. My plan is to sow now in a broad pan 3 inches deep, put in a vinery at work, having a temperature of 55°. The seed must not be covered more than a quarter of an inch deep, and very fine soil should be employed for that purpose. It is advisable to keep the pan shaded until the seedlings appear, otherwise it will be necessary to water twice a-day when there is much air and sun.

When the seedlings come up they must be well looked after, for I find every sort of insect will eat them off almost before you can see them. To prevent this, about a week after they make their appearance I give them one watering of weak guano water through a very fine rose, and then in a few days I shake a slight dusting of soot and lime on them. If they begin to damp off, which they often do in a moist vinery, I take them to a drier place, but warm; if not, I prick them off in 60-sized pots in the vinery, put them under hand-glasses, and shade well until they are pretty strong. In about a fortnight I remove them from the vinery to a warm dung frame, the dung being covered with ashes to prevent their rooting into it. Afterwards I keep them in the frame, harden off by degrees, and plant out as soon as I think we are safe from frost, which is here generally about the first week in June.

The plants will grow in any place not too hot and dry. If the weather should prove very dry I stir the soil with a fork, and give them a good soaking of guano water early in the morning, then cover the ground over with a mulching of leaf soil. No one should be disappointed if his plants do not grow so strongly as here, for the soil is peculiarly well suited for the growth of Tobacco, being light and porous, and we have much rain at midsummer.

Tobacco ought never to be pulled up before there are signs of the approach of a sharp frost, for the older it is the stronger. I pull up the plants by the roots, lay them in an open shed for the night, and hang them up next day as thinly as I can. I let them hang about two or three weeks to dry a little, and then I have the leaves picked off and put in a tub to ferment. Sometimes they take a month or six weeks to do this, and during that time I turn them once. When the tobacco has well fermented, shake it out on some dry shelves or staging to dry. Lay the stems on a boiler at work. In about a month or six weeks chop the stems up with a billhook, and mix them with the leaves, and the tobacco will be ready for use. If there are plenty of leaves without having to use the stems, so much the better.—RATU.

INTERNATIONAL HORTICULTURAL EXHIBITION.

We are authorised to state that the Executive Committee of the International Horticultural Exhibition have ruled as follows on certain points relating to the Exhibition which had been officially brought before them. As the replies may be of use to others besides those immediately concerned, it has been thought desirable to give them publication in the present form.

In respect to Variegated Plants, the inquiry was put whether *Anthurium cordifolium*, and the *Alocasia Lowii*, Veitchii, and zebra, were admissible as variegated plants under Class 17 of the schedule. It was ruled by a majority of votes that they were not to be admitted. Another inquiry as to the same plants, also *Alocasia macrorrhiza*, being eligible to be shown in Classes 14 to 16 inclusive, was made, and it was decided that they were eligible in those classes. It was further ruled that variegated plants—a group exceedingly difficult of accurate definition—were to be understood as those having two distinct colours on the upper surface of the leaf, exclusive of that of the costa and ribs. This applies also to Class 25.

As regards Orchids, in reply to a suggestion that Class 28, that for twenty distinct sorts, should be taken as the leading collection in that group of plants, the Committee thought it sufficient for them to point out, that Class 27 was intended by them to include a mass of showy plants staged entirely for their effectiveness and splendour, while Class 28 was intended for specimen plants of distinct kinds, showing high cultivation.

The first six classes in the schedule relating to New Plants had given rise to the inquiry whether specimens of the same species (duplicate plants) were admissible in more than one class. This was ruled in the affirmative. One querist desired to know if tree Ferns might be shown in Classes 42 to 45, and was told, Yes, though their exhibition there would confer no special advantage, as they would have to be judged as Ferns, not as tree Ferns. Another inquiry related to hardy Conifers, in this form—Is novelty or size and beauty to be the test of merit in Classes 61 to 63? The reply was to the effect that size and beauty combined were the qualities to be preferred.

An intending exhibitor desired to know how Forced Vegetables (Class 201) were to be determined—what was to be understood by forcing? It was in this case ruled, that to be forced the vegetables must be grown by the aid of artificially applied heat. Mere protection was not to be understood as constituting forcing.

The classes for Designs and Water-colour Drawings; also elicited some inquiries which may be answered thus:—The designs must be tinted in the usual way; they must be mounted so as to admit of being suspended against a wall, framing and glazing being optional; and they must be sent in with mottoes. As to the drawings which are

invited on folio paper, this was ruled to mean any folio not larger than imperial, and these also are required to be mounted or framed, so as to be easily suspended.

We may add that the Committee decided in favour of holding an auction sale in the tent on the Saturday following the Show day, for the sale of such of the exhibited subjects as their owners might desire to dispose of in this way.

A Yorkshire correspondent writes as follows in respect to the *Admission of Gardeners* at the forthcoming International Exhibition:—“Many gardeners about the country wish to know if there will be a day devoted to them, say a 2s. 6d. day? If not an entire day, there should be at least the half of one day given up to them. I have heard that the mornings up to 9 o'clock are to be given to the gardeners, but as it will be impossible to get more than a passing glimpse of things in two or three hours, it would not only entail additional expense but great waste of time if they had to go two or more mornings.” This correspondent and others will be glad to learn that the Executive Committee have already decided that *bona fide* gardeners shall be admitted on the 23rd for 2s. 6d., and on the 24th for 1s., provided tickets are secured before the 1st of May; these tickets admitting—not from 6 to 9 A.M. as originally set down in the regulations, but from 10 A.M. to 7 P.M., that is during the whole time the Show is open to the public. We think this is a just concession to the class of practical gardeners, from whom the Show itself must derive its chief attractions, and we trust they will know how to profit by it.

The same correspondent adds:—“I would also suggest to the Executive that steps should be taken to induce all the railway companies to run special trains at excursion prices for the Exhibition, say for three days, chiefly to accommodate gardeners, who cannot in the month of May spare much time from home.” We can, in respect to this matter report that the convenience of gardeners and exhibitors, so far as travelling is concerned, has not been overlooked. The principal railway companies, including the London and North-Western, South-Western, South-Eastern, London, Chatham, and Dover, Brighton, Great Northern, and Great-Western, have undertaken to convey subjects for the exhibition at half rates. They point out, in respect to passengers, that, the Show being held during Whitsun week, there will be unusual facilities for cheap travelling; but the Committee hope to obtain further concessions, not only from the foregoing, but from other companies, and if they are successful in their efforts, the gardening community, we may venture to say, will be duly apprised thereof.

ROYAL HORTICULTURAL SOCIETY.

APRIL 3RD.

FLORAL COMMITTEE.—At this meeting Messrs. Veitch & Sons were the principal exhibitors. A first-class certificate was awarded them for *Maranta splendida*, a very beautiful-foliaged plant, distinct from any other species, with dark green markings on a lighter ground; one of the second class for *Angraecum* species, from Madagascar, a very pretty white Orchid; a singular award for *Dieffenbachia gigantea*, a useful fine-foliaged plant; and a first-class certificate for *Camellia Triomphe de Lodi*, a beautifully-formed pale flesh-coloured flower, with pale stripes. Messrs. Veitch also exhibited *Ananassa Porteana*, which it was requested should be sent again, *Aucuba bicolor*, *Camellia L'Insubria*, and *Camellia Stortvii*, very pretty. Special certificates were awarded to the same firm for a very beautiful collection of seedling Sparaxis, containing many very pretty varieties, and for a miscellaneous collection of plants. Among these was a basket containing specimens of Mr. Veitch's exquisite *Azalea Stella*, the plants covered with brilliant scarlet flowers. This *Azalea* was awarded a first-class certificate on a former occasion.

Messrs. E. G. Henderson & Sons exhibited a specimen of *Pelargonium Sophia Cusack*, one of the highly tricoloured section of which Mrs. Pollock seems still to stand at the head. This seedling appeared to have more red in the zones; it was requested that this plant should be sent again later in the season. *Pelargonium Beauty of Guestwick*, a white variegated-foliaged seedling, also from Messrs. Henderson, was required to be sent again. First-class certificates were awarded them for *Enonymus japonicus macrophyllus*, a distinct and useful shrub with broad leaves, said to be hardy, and *Cynosurus cristatus argenteus*, a most beautiful variegated form of the Crested Dog-tail Grass. This will be a most useful plant for edging-purposes, the white being so clear and distinct. *Lysimachia floribundum* producing flowers something like an *Epacris*, *Enonymus alatus*, and *Enonymus japonicus radicans pictus* also came from Messrs. Henderson.

Mr. Standish, Ascot, sent a specimen of the true *Rhododendron Griffithii*, with very large pure white flowers, perfumed like the Hawthorn. This beautiful plant was much admired, and received a first-class certificate. Mr. Watson, St. Albans, brought a small plant of a seedling *Pelargonium*, Miss Watson, one of the tricoloured section, with very distinct and bright zones, a very promising variety. He was requested to send it again later in the season.

Mr. Green, gardener to W. Wilson Saunders, Esq., exhibited a collection of curious and interesting plants, for which a special certificate was awarded. Among them were *Sauromatum asperum*; a species of *Amorphophallus*; *Bonatea speciosa*, a Cape Orchid; and *Hippeastrum regium*. Mr. Blair, gardener to Sir G. W. Broke Middleton, Bart., Shrubland Park, exhibited out specimens of *Bougainvillea*

speciosa, for which he received a special certificate; and Messrs. Haug and Schmidt, Erfurt, two seedling Myosotis, not in cultivation. Several plants from the Society's garden were placed on the table, and among them were Ficus Coppen, and Mr. Weir's Odontoglossum Alexandri.

FURTHER COMMUNICATIONS.—G. F. Wilson, Esq., F.R.S., in the chair. From Messrs. Ivery & Son, of Poking, came a seedling Apple raised by Mr. Birkley, of that place. It was rather below the medium size, yellow, streaked and dotted with red next the sun. It was awarded a first-class certificate as a good late Apple. Mr. J. Staudish sent a well-grown Fine Apple; and Mr. Fenn, gardener to the Rev. G. W. St. John, Woodstock, several bottles of British wines, made from Royal Massachusetts Espineroe Grapes, as described in the pages of this Journal; also, Gooseberry wine, Rhubarb wine, mead, and mead vinegar.

SCIENTIFIC MATTERS.—G. F. Wilson, Esq., in the chair. The awards of the Committee, having been announced, the Rev. M. J. Berkeley said: "The first plant to which he would direct attention was a species of Angraecum, from Madagascar, shown by Messrs. Veitch and Sons, which was something in the way of A. pictum, but in all probability perfectly distinct. The genus Angraecum it was remarked, was almost entirely African, and its representatives were particularly abundant in Madagascar. Bonatea speciosa, sent by Mr. Wilson Saunders, then came under notice; it was one of the Cape Orchids, among which there were many beautiful species, such as Dischidanthus, but on account of the difficulty experienced in their cultivation, they were less generally grown than they deserved to be. With respect to the variegated Cyrtosium crinitum, Mr. Berkeley said there was another variegated variety, but with a great deal more green in it. It was worthy of remark, that in some districts almost every plant became variegated, and as an instance, the neighbourhood of Hounslow was mentioned. At Hatton, near that place, the Lord Chief Baron had in his garden an excellent collection of variegated plants which had been found in the district. The flowers of Lysium flabellatum were next referred to as forming pretty objects under the microscope; and the extremely fragrant white-flowered Rhododendron Griffithii, from Mr. Staudish, was stated to be a Blean species, of which R. Ancklandii was by some considered to be only a form. With reference to Camellia L'Insubria, Mr. Berkeley remarked that Insubria was the ancient name of Lombardy, whence, and from other parts of Italy, so many varieties of the Camellia had been obtained. The mention of Italy recalled to his mind a circumstance in connection with that kingdom and the Camellia. Some years ago a gentleman sent to him a Camellia leaf, attacked by a peculiar fungus, and he (Mr. Berkeley) wrote asking whether the plant came from Italy, for he had seen the same fungus on Orange trees from that country, and the answer was in the affirmative. This happened four or five years ago, but he had heard no more of the fungus, and he hoped he should not, for his efforts were very disastrous. Ficus Coppen, which had been exhibited at a previous meeting, was now produced with ripe fruit on it; but on tasting them they had been found absolutely insipid. In connection with Ficus, he might mention that a curious discussion had arisen as to whether it was not possible to ripen Ficus on standards out of doors in the midland counties. He knew in one of these a F. on a standard which had been planted a great number of years, but the trees had never ripened fruit more than once in forty years, and that only in an exceptionally hot season. He, therefore, could not recommend any one to make the attempt. At Hastings, Margate, and other places on the south coast, Ficus would ripen abundantly and well, and near Margate, he had seen them lying beneath the trees as thickly as Mallonies, ripe, and of fine flavour. Before concluding his remarks, Mr. Berkeley observed, that amongst other experiments instituted at this Society's garden, was one commenced the day before. It was an attempt to cultivate the Truffle, and though a considerable difficulty had been experienced in obtaining Truffles for the experiment, a bed of them had at length been procured, and the bed for their reception was to be at once prepared. Many similar attempts had been made, but all had turned out unsuccessfully, still it was to be hoped that, though late in the season, some result might be obtained, if not this year, then in the next. Mr. Berkeley then instanced several attempts which had been made to grow Truffles, such as that of Comte Noe, a French emigrant during the revolution, who, being one of the few who were fortunate enough to recover their estates, on his return to France, fenced in part of a forest, and watered it with water in which Truffles had been steeped. What is wanted, however, is to grow Truffles in the same way as Mushrooms—by spawn, and if this could be made to run the result would be very remunerative. Some years ago a treatise was published by Bornholz, and the plan recommended seemed to be very good, but the book was probably only a bookseller's speculation, and not the result of actual experience; at any rate all attempts to carry out the plan recommended terminated without success. Still later, a Mr. Disney made some experiments in Truffle-growing in Essex, but on going down to see what the results were, Mr. Berkeley said he was not surprised to find they amounted to nothing, when he was informed that the Truffles used in the experiment were the sweepings of Fortnum & Mason's drawers. A few years ago another stated he had succeeded in getting the spawn to run, and in making spawn bricks; but this, too, came to nothing. In Poitou, whence a large portion of the supply of the Paris markets is derived, and where the Truffles are of a different species from ours, being

black, a plot of ground is fenced in from the downs, sown with acorns and in ten years a crop of Truffles is obtained. They last for about twenty-one years, after which the old grounds cease to be productive, and new ones have to be prepared. An impression, said Mr. Berkeley, prevails in this country, that Truffles will only grow under Beech trees, but he had seen them under Spruce Firs, and he thought the kind of tree did not matter, so long as the soil was calcareous. One point, in particular, with regard to Truffles, was, that they do not like to be disturbed, accordingly they are hunted by dogs trained for the purpose, and these incidents where the Truffles are to be found. As an example of the evil results arising from disturbing the ground, he instanced the case of a gentleman who had a plot of ground from which in three or four hours, or 4 lbs. of Truffles could be collected; the gentleman had it dug over and not a single Truffle had been seen since. Although the experiment at Chiswick had been commenced rather late in the year, he hoped if it led to nothing else, that something might be learnt of the nature of the spawn.

Thirteen new members were elected, and the Maidstone Horticultural Society was admitted an union.

WREARY SHOWS.—Prizes were offered at this meeting for a collection of twelve bulbs in flower, of which the first was taken by Mr. Young, gardener to R. Loring, Esq., Highgate, and the second by Mr. Bartlett, of Southbury Terrace, Hammersmith; also for the best greenhouse plants in flower, the first being taken by Mr. Bousley, gardener to Mrs. Wood, Twyford Abbey, Acton, and the second by Mr. Young. For the best twelve cut Blooms of Camellias, the first prize was awarded to Mr. Turner, gardener to D. J. Kay, Esq., Huddersfield, and the second to Mr. Young. Extra prizes were awarded to Mr. Young for a collection of Hyacinths, and to Mr. Bartlett for a collection of bulbs and a collection of plants. Mr. Rivers, of Southbury, worth, sent a collection of Apples and Pears in a beautiful state of preservation at this late season. The former consisted of Nonfil, Beano, Newtown Pippin, Rhode Island Greening, Lodgemore Nonpareil, Mela Carla, Stamford Pippin, Reimette Dieck, Lamb Abbey Pearmain, Calville de Chavy, Baxters' Pearmain, Scarlet Nonpareil, Belle d'Angers, Dominica, Pearsons' Plate, Baldwin, Forge, Betty Gosson, and Cadde Pippin. The Pears were Bozi Mai, Colmar Van Mons, Easter Beauty, Beurre Permain, Beurre Brutoineau, Morel, Madame Miller, and Beurre d'Haye. These received a first prize, and the second prize was awarded to Mr. Tonkin, gardener to G. T. Kitchin, Esq., of Epsom, for a very handsome Smooth Cayenne Pine.

THE ROYAL BOTANIC SOCIETY'S SECOND SPRING SHOW.—APRIL 7.

This took place on Saturday last, and as Anders constituted the principal feature, the Exhibition tent presented quite a gay appearance, notwithstanding the rather gloomy character of the day. From Mr. Turner of Southbury, came half a dozen pyramidal plants standing about 5 feet high, pots included, and covered with bloom. The varieties were Citronella, Duc de Nassau, with large rosy purple flowers; Paragona, Marquise, white; Prince Jerome; and Variegata superba and Etoule de Gand, constant one plant called Union. Messrs. Lane & Son, of Great Berkhamstead, contributed well-bloomed examples of Magnificent, Chelidon, Conspectus purpureus, Reine des Blancs, very large, pure white; Pyramidiflora, and Eulalie Van Gout, a large reddish-spotted sort. Messrs. Lane likewise furnished a numerous collection of smaller plants, among which were Madame Antoinette Verschaffelt, a very pleasing rose, bordered with white, and conspicuously spotted in the upper petals with dark crimson; Leopold II, very large, rose; Perfection, bright rosy crimson; President Charles Admon, edged with white; Sir H. Havelock; Elegantisima, white, occasionally edged with red; and Duke of Cambridge. Of Azaleas sent out in 1862, 1863, and 1864, Messrs. Lane exhibited Souvenir du Prince Albert, semi-double, rose, broadly edged with white, very showy; Advanee, in the way of Perfection, but larger and deeper in colour; and S. Octave, Claus, very large, bluish, spotted with crimson. From Messrs. Ivery & Son, Poking, came Flag of France, white; Madame Dominique Vervane, delicate rose, spotted in the upper petals with crimson; and Madame de Cannaert d'Hamale, large and very fine, white, occasionally striped with crimson. Mr. Turner had Belle Gantoise, pink, edged with white, boldly spotted in the upper petals with crimson; Sir J. Outram, orange scarlet, very free-flowering; and Louise Von Baden, a very fine white, of good substance. Of absolutely new kinds, Messrs. F. & A. Smith contributed several, one of which, Magnum Bonum, received a second-class certificate. It is an orange-red, slightly spotted in the upper petals with crimson. Mr. Bail exhibited Azalea punctulata in its different forms; President Humann, rose, spotted with crimson; and President Victor Van den Heek, white, striped with deep rose.

Awards.—For six amateurs: first, Mr. Wheeler, gardener to Sir F. Goldsmith, Barr., Regent's Park. For six nurserymen: first, Mr. Turner; second, Messrs. Lane. For three varieties sent out in 1862, 1863, and 1864: first, Messrs. Lane; second, Messrs. Ivery; third, Mr. Turner. Collections of ornamental-leaved Begonias from Mr. Wheeler, Mr. Young, gardener to R. Barclay, Esq., and Mr. Marcham, gardener to

E. Oates, Esq., Hanwell, were awarded prizes in the order in which the exhibitors are named. Though not large, all the plants were in excellent condition. *B. riciniifolia maculata* was noticeable for its deeply-cut foliage of a deep velvety green on a paler ground, and Madame Albert and Madame Ollham as having fine silvery markings. Messrs. F. & A. Smith contributed half a dozen plants of *Erica Willmorei* in good bloom. Miscellaneous collections of fine-foliaged and flowering plants from the same, Mr. Williams, and Mr. Wheeler, comprised *Dicksonia antarctica*, *Alocasia metallica*, *Pandanus*, *Eriostemon*, *Azalea*, *Heaths*, *Acacias*, *Cyrtis*, &c.; and from Mr. Williams we noticed excellent plants of *Cordyline indivisa*, the variegated *Aloe-leaved Yucca*, and *Hedera Hookeri* in very good bloom. Mr. William Paul had likewise a miscellaneous collection, consisting of broad-leaved *Kalmias*, *Dentzias*, double-flowering *Peaches*, and *Rhododendrons*, among which *Bylsianum* and *Poisson* were very bright and attractive, and *Pastuosum* was blooming very freely. *Rhododendrons*, dwarf plants, in small pots, and in fine bloom, also came from Messrs. Lane.

Collections of *Cinerarias* in good bloom were furnished by Mr. James, gardener to W. Watson, Esq., Isleworth; Mr. Cox, gardener to Capt. Cabill, Southall; Mr. Marcham; Mr. Clarke, Whitting, and Mr. Beech, gardener to W. Rogers, Esq., Redhill. Several seedlings were also exhibited; by far the best was *Perfection* from Messrs. F. & A. Smith, which received a first-class certificate. It is of a rich violet purple, with a narrow ring of crimson at the base of the ray florets, and a narrow ring of white round the disk. It is a very large and showy variety, and a decided acquisition.

A small collection of *Amaryllis* was exhibited by Mr. Young, and a dozen *Gloxinias*, chiefly erect-flowering, came from Mr. Ballenger, gardener to F. Shadoll, Esq., Highgate. Messrs. E. G. Henderson contributed a collection of *Cyclamen persicum*, beautifully grown and bloomed, and the same remark applies to a dozen pots of *Lily of the Valley* from Mr. William Paul, who also exhibited *Zonale Pelargonium Rebecca*, remarkable for its fine, large, rose-scarlet flower, and breadth of petal. A first-class certificate was awarded for it. Messrs. E. G. Henderson, in addition to the *Cyclamens* already noticed, had a collection of tricolor-leaved and variegated *Geraniums*, *Sunset* and *Sophia Cusack* being two of the most beautiful of the former; and the variegated *Cynosurus*, noticed in another column, was also again produced.

Of *Roses* Messrs. Paul & Son, of Cheshunt, showed four boxes of cut blooms, conspicuous among which were *Teas* *Maréchal Niel* in great beauty, *Gloire de Dijon*, and *Rosea alba*, and *Hybrid Perpetuals* *John Hopper*, *Senateur Vaisse*, *Lord Clyde*, *Lord Raglan*, *Beauty of Waltham*, *Pierre Notting*, and *Princess Mary of Cambridge*. Of other subjects hardy British Ferns were shown by Messrs. Ivory and Mr. Bull, those from the former comprising a nice *Wardian case* of *Trichomanes radicans*; and among those from Mr. Bull were very good examples of *Hymenophyllum tumbridgense* and *Trichomanes speciosum*. Mr. Bull also contributed a variety of novelties, and received a first-class certificate for *Maranta splendida*, and second-class ones for *Dieffenbachia gigantea*, and *Aspidistra Sieboldii*, with dark green foliage broadly striped with pale yellow, one half of the leaf being sometimes entirely yellow, and the other half green. Other plants were the pretty yellow-flowered *Berberis stonophylla*, *Psychotria macrocephala*, with ample deep-green foliage, and heads of white flowers; and *Meyenia Vogeliana*, violet, with a yellow throat. *Imantophyllum minimum superbum* in excellent bloom, and a leaf of *Coccoloba pubescens*, about 3 feet across, were also shown by the same exhibitor.

Awards:—For *Cinerarias* (Amateurs): first, Mr. James; second, Mr. Cox; third, Mr. Marcham. (Nurserymen): first, Mr. Clarke; For *Amaryllis*: first, Mr. Young. For *Lily of the Valley*: first, Mr. W. Paul. For British Ferns: first, Messrs. Ivory; second, Mr. Bull. For Miscellaneous Flowering and Fine-foliaged Plants: first, Mr. Williams; second, Mr. Wheeler; third, Messrs. F. & A. Smith. Miscellaneous: Silver Medal to Messrs. Lane, for *Azaleas*; Small Silver Medal to Messrs. Lane, for *Rhododendrons*; Messrs. Paul and Son, for cut *Roses*; Mr. W. Paul, for Miscellaneous Plants; Messrs. E. G. Henderson, for *Cyclamens*; Bronze, Mr. Ballenger, for *Gloxinias*.

METEOROLOGICAL NOTES—LINTON PARK.

WATER! water! the very name of which last September had so refreshing a sound, threatens now to deluge us with its abundance. Rain, varied by sleet, or now and then falls of snow, has so far soaked the ground as to apparently leave no room for more to be absorbed; and, consequently, our rivers and streams become flooded with only a fraction of the rainfall that would be required after a period of dry weather in the latter part of summer, the thirsty ground at that time swallowing up more rain than I have ever known fall in one day in this district. Saturated, however, as the ground now is (March), a small quantity will suffice to make an impression on our streams.

Mr. Perkins's record of the rainfall of Suffolk bears a great resemblance to that of the place from which I write, only we have had somewhat more rain in the seasons he notices, and the present year has been unusually wet also. Subjoined I

give a table of the monthly rainfall of 1858, 1860, 1864, and 1865, the figures denoting the fall in inches and hundredth parts of an inch:—

	1858.	1860.	1864.	1865.	1866.
January	0.78	2.87	0.77	4.48	3.83
February	0.77	1.49	1.36	2.39	4.55
March	0.80	2.61	3.06	2.11	
April	1.93	2.81	0.59	0.38	
May	2.16	3.12	2.35	2.89	
June	0.67	5.09	1.34	1.17	
July	2.69	2.07	0.63	3.48	
August	1.20	3.54	1.63	5.26	
September	1.19	3.36	2.59	0.08	
October	1.43	1.71	1.47	8.04	
November	0.77	2.07	4.59	2.74	
December	1.91	2.88	1.11	1.93	
Total	16.33	33.66	21.25	35.08	

By the above it will be seen that more rain fell last year than in 1860, the wet year as it is called; but the fall was better distributed, and accompanied by a much greater amount of heat than usual, and besides that, the rain that fell in the summer months came down in something like a succession of thunder showers, with intervals of bright weather between. No evil effects followed its during the months of July and August, when we had such a plentiful supply. September and October were, however, the most remarkable months, the former being the driest and the latter the wettest I have any record of; in fact, from the 21th of August to the 8th of October only 0.08 inch of rain fell, and the heat during the first twenty days of September, taking both night and day together, exceeded that of any like consecutive number of days since 1857. Rain, however, set in on the 9th of October for two or three days, but the wet period did not commence until the 18th, from which time to the end of the month upwards of 6½ inches fell, being fully half an inch a-day. November and December were mild, and more remarkable for dull, drizzling rain than for any heavy fall. January and February of the present year have, however, been unusually wet, the latter month especially so; for here, taking the average of ten years prior to 1865, February is the driest month of the year, and September the wettest. The rainfall of the last three months of 1865, and first two of the present year, has been excessive; but of snow we have not had much, neither have the sharpest frosts produced ice more than half an inch thick; still the many changes, combined with some slight frosts about the end of February, destroyed many plants that withstand a mild winter. Returning to the meteorology of 1865, I may say that January was wet and changeable; February cold, with frequent slight falls of snow; March also cold; but April very warm, dry, and fair, only one frosty night being recorded—a most unusual circumstance. In May there were three frosts, and on the whole it was a favourable month. June was very dry, no rain falling from the 3rd to the 29th. July was a showery and growing month; August equally so up to the 21th, after which it was dry and hot, the drought continuing throughout September and up to the 9th of October, when three wet days were followed by four or five fine ones, and then the rest were all wet. November and December were mild, dull, and wet, with scarcely any frost—so little, in fact, that *Geraniums* out of doors were quite fresh up to the 11th of January of the present year, when a rather heavy snow-storm and two nights' frost destroyed them. High winds have been frequent during the winter, and during the summer of last year we had very little thunder.

To all interested in the amount of rainfall in the different parts of Great Britain, I would recommend a perusal of Mr. Symon's "Rainfall for 1865," and former years. That for last year gives upwards of one thousand stations in the United Kingdom, and, of course, there is a considerable difference amongst them; but, as a general rule, the western parts of the kingdom are wetter than the eastern, the driest of all being Norfolk and Suffolk. At certain stations on the Cumberland hills, in some years as much as half an inch a-day is recorded for the whole year, and on some occasions even 6 inches have fallen in one day, and upwards of 15 inches in four consecutive days. At none of the Scotch stations, although similarly placed as to elevation, &c., does the amount approach this.

For the information of those who take an interest in other meteorological observations besides those of rainfall, I may add that the prevailing winds during the past year at this place, as noticed at noon each day, have been from the south and south-west; for, taking the eight cardinal points as they come, the wind has been as follows:—East, 28 days; south-east, 45; south, 59; south-west, 74; west, 36; north-west, 29; north, 35; north-east, 55; and four days were not ascertained. The num-

ber of rainy days was 172, against 216, in 1860, and there was frost on 80 days. The hottest day was June 21st, and the coldest February 15th. The highest reading of the barometer was on December 10th, 30.37 inches, and the lowest on January 14th, 28.14. I may further add that the average rain-

fall at this place for the ten years ending with 1864, is 24.75 inches, so that the fall in 1865 was nearly 50 per cent. in excess of the average, and what we have already had in the first two months of 1866 is more than three times the average of these months.—J. ROUSSEAU.

CULTURE OF VINES IN POTS.

(Continued from page 253.)

It is a common practice after preparing the eyes to insert a dozen or more in a pan, and after they have struck and begun to grow to pot them off into small pots. The advantages of this system consist in the necessity for watering being diminished, and they are, consequently, not so liable to rot or become blind, and a more equable temperature is secured than were they inserted singly in small pots at first. These advantages, however, I have found more than counterbalanced by the check received on potting the eyes after they have been struck. I find they receive a serious check on being taken from the pan, and potted into small pots; for however carefully the operation may be performed, it is not possible to avoid breaking the roots more or less.

Some, again, grow the canes for fruiting in nine-inch pots, and supply them largely with liquid manure. Of this practice, also, I am no advocate. In small pots fruiting canes are either highly fed by liquid manure, or the roots have been allowed to extend from the pot into a border of rich soil. In the first case, the continual stream of liquid manure converts the soil into a soapy black mass, and the roots lose most of their fibres at the fall of the leaf; besides, there cannot be nearly so many roots, and consequently mouths, in a small pot as in

a large one. In the other case the roots, from being allowed to extend beyond the pot, are for the most part (and the better portion of them) lost to the cane the year of fruiting. To insure the Vine breaking well there cannot be too many fibrous roots in the pot it is to be fruited in; but when the canes have been allowed to root through, or are potted into larger pots, it is necessary that these should be plunged in a hotbed of about 70° for a fortnight or three weeks, the top heat from fire heat being kept at from 40° to 45°. The accompanying end sections will show means for furnishing bottom heat for a time, and afterwards a medium for the Vines to root into.

Fig. 1.

Fig. 1 shows a span-roofed house 12 feet wide, with a walk in the centre and a border of soil on each side, 18 inches deep, over rubble. The pots are placed a couple of inches deeper in the soil than the side holes in the pots, through which, and that

at bottom, roots will be protruded in due course. It is not a desirable form of house for early forcing, but will do after Christmas. The soil of all the borders should consist of turves a year old, chopped with a spade, and one-sixth of boiled half-inch bones. Over the drainage a layer of sods, grass side downwards, will keep the rubble from becoming choked up with

Fig. 2.

soil; and under the drainage or rubble should be a drain to carry off the water. No manure is to be mixed with the soil, as it is best given on the surface.

Figs. 2 and 3 are the same in their internal arrangements, both having convenience for fruiting Vines and raising young ones in the centre bed a, which should be filled with new tan

about Christmas, ready for the eyes early in January, and it will be useful for other things at that season until the young canes require the whole of the space. The side borders, *b*, *fig. 3*, are of soil, for this house is not eligible for early forcing ;

those of *fig. 2* may be filled with dung and leaves, the pots being plunged therein to three-quarters of their depth until the Vines break, when they are to be gradually lifted out ; soil should then be placed on the dung and leaves to the depth of

Fig. 3.

6 inches, the pots remaining plunged that depth always. *Fig. 2* will answer for early forcing.

and a border in front, in which the pots are plunged about an inch deeper than the rim, and the roots not only come through the bottom of the pot and the holes in the sides, but over the

Fig. 4 is a narrow lean-to, 7 feet wide, with a walk at back

Fig. 4.

Fig. 5.

rim, and the canes carry a much heavier crop in this way than in any other with which I am acquainted.

an opening at every 2 feet for a circular ventilator, 6 inches in diameter, which can be opened much or little at will. The air entering there becomes heated before it reaches the Vines.

Fig. 5 is simply a narrow lean-to, 9 feet wide, and this and the preceding are the most suitable for early crops. They have guttered pipes back and front, and in the front wall is

The scale of all the sections is 5 feet to the inch.—G. ABBEY.
(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERYTHING connected with this department should now be kept in good order. Take every opportunity of eradicating weeds; hand-weed where practicable, as it more effectually answers the purpose than hoeing and raking when the soil is

moist. Cut Box-edgings, and keep the walks well rolled. *Basil*, a warm sheltered spot may now be chosen for a sowing in the open ground; but as it is a rather tender annual it is generally the best plan to sow in pans, or on a slight hotbed, and afterwards plant it out. *Beans*, earth-up the early crops, but be-

fore doing so lay a little soot close to the stems as before recommended, and branches of evergreens stuck pretty thickly on each side of the rows will be found serviceable in protecting them from frosty winds. Keep the soil between the rows free from weeds, and open by frequent stirrings. *Broccoli*, make a sowing for the early crop; what is commonly called the Scotch Kale is the best variety. *Cabbages*, pull up any of the plants that are running to seed in the autumn plantation, and fill up from the reserve bed. During dry weather the plants should be supplied with water, and the soil kept free and open by a frequent use of the hoe or fork. *Celery*, the main sowing for the winter crop should now be made. Continue to prick-out from the early sowings. Clean and earth-up any that has stood the winter, as, if it is of no other use, it will do for soups. *Cucumbers*, keep a brisk heat in the beds as the days lengthen and the weather increases, bearing in mind that light and heat should be proportionate to each other; give air daily in a greater or less degree, and keep the lights free from dirt. If green fly or thrips appear, recourse must be had to fumigation, which will generally exterminate them. *Kidney Beans*, the bearing plants will now require a good supply of water at the roots, as well as frequent sprinklings overhead. A sowing may be made on a warm sheltered border when the soil is favourable for early crops, or make a sowing in pots for planting-out as soon as all danger from frost is over. *Lettuces*, give air to the plants in frames night and day in mild weather. Loosen the soil about those planted in the open air. If the crops of *Onions*, *Leeks*, *Parsnips*, *Beet*, *Salsify*, *Sew-onion*, and *Skirret* are not yet sown they should be no longer delayed; and the main crop of *Carrots* should be sown if the ground is in good order. In sowing *Pots*, it is the most workmanlike method to put the stakes to them at once, as, by so doing, the barren appearance of the ground is removed, and no more tramping on it is necessary for a long time, besides which they afford a slight shelter to the young plants on their first appearance above ground. *Spinach*, sow once a fortnight, and *Peas*, *Beans*, and *Turnips* once in three weeks. Sowings of all salads should be made with strict regularity; and proper attention must be paid to protecting all kinds of seeds from the ravages of birds and insects. *Khubarb* will now be coming forward so rapidly out of doors that the forcing of this useful vegetable will no longer be necessary.

FRUIT GARDEN.

Look to blossom-protection on the walls. Clean Strawberry-beds, and thin the suckers from Raspberries, leaving three or four strong ones to each stool. If strong young plants of the Elton Strawberry are lifted this month and planted behind a north wall, they will produce a crop in August and September, and will keep up the succession, along with Alpines, to the latest period. On the first appearance of green fly on the Peach and Nectarine trees syringe these with tobacco water two evenings in succession; if done properly it will stop their career for the season. The mining grub, so destructive to the Apricot and Plum, may be easily detected by the leaves being folded up; the best cure is to crush them between the fore-finger and thumb. See that wasps are destroyed, as every one that appears now forms a colony in the summer.

FLOWER GARDEN.

Now, with April showers and bright and occasional warm sunshine, we must be in readiness for mowing. Have the turf swept, well rolled, and made thoroughly firm without loss of time, and remember if the first mowing is deferred until the grass become long it will require much time and labour to bring the turf into proper order. Patches of some of the more showy of the hardy annuals may now be sown in the vacant places which usually exist in the herbaceous beds, and in the edges of clumps and borders in the shrubbery. A sufficient quantity of cuttings and seedlings should be potted for planting out in May. With such plants as *Cobaea*, *Maurandias*, *Diosporiums*, *Tropaeolum canariense*, many bare places on the walls and trellises may be covered and made ornamental. Also plant-out Wallflowers, Double Rockets, and young stock of herbaceous plants generally. Trine Tea and other Roses not already pruned, and attend to any shrubs that may require that attention.

GREENHOUSE AND CONSERVATORY.

Besides the permanent plants in the conservatory, many choice plants in pots will be required to keep up a succession of gay flowers during the summer. Among the finest for this purpose are *Bignanias*, *Erythrina crista-galli*, *Timbergias*, *Stephanotis*, *Mandevilla suaveolens*, *Allamandas*, *Echites*, *Achimenes*, *Ipomeas*, with *Heaths* and *Pelargoniums*. Let

these have all possible attention, and bring them forward in several lots, so that one set may succeed another. Pay particular attention to the Lilies now in pots, by giving them a liberal supply of water, and by neatly staking them. A top-dressing of turfy peat, sand, and well decomposed cowdung, will be of great benefit to them, and they will be very useful for conservatory or drawing-room decoration late in the autumn. Let *Fuchsias*, which are so useful for summer and autumn flowering in the conservatory, be repotted as they require it in rich compost, watering them occasionally with liquid manure. Nearly all the varieties have a natural tendency to form conical bushes, and, by a very little attention, they may be guided into this appropriate form. One strong shoot should be selected to form a leader, and should be trained perfectly upright, the remaining shoots being regulated by stopping any which are growing more luxuriantly than is consistent with the proper shape of the plant. Violets are everybody's flowers, and, to have them fine and in abundance, they require and well merit some share of attention, particularly where they do not naturally succeed well. In some situations they grow so strongly, and flower so abundantly, that they merely require at this season to be taken up, parted, and replanted, and, if kept free from weeds, all will go well; whilst in other places they frequently cause me trouble than a collection of Auriculas. A frame on the north side of a wall is the most likely situation for preventing the attacks of the red spider, to which they are very liable, and which cause them to lose their foliage during the winter. About the beginning of September they should be planted in a frame upon a spent Melon or Cucumber-bed, where they will have time to establish themselves well before winter, and if frost is excluded, and plenty of air given at all times during fine weather, perfect success may be expected. In the greenhouse the leading shoots of *Epacasis*, *Chorizanthes*, *Cornus*, *Heaths*, together with many other choice plants that produce the best effect in a bushy condition, should be frequently pinched or stopped in order to form good specimens; also those of *Calceolarias*, *Verbenas*, and other young stock intended either for decorating the flower-beds or for succession in pots.

STOVE.

Proceed with the repotting of such plants as require it, and give all necessary attention to those in active growth, using every means to induce rapid growth, combined with strong short-jointed wood. The only way of effecting this is by securing vigorous root action, and keeping the plants near the glass. *Ixoras*, *Clerodendrons*, *Allamandas*, &c., "feeling their pots," will be greatly benefited by a careful supply of manure water, but see that it is given in a tepid state.

PITS AND FRAMES.

Attend carefully to the stock of bedding plants, pot-off rooted cuttings as soon as they are in a fit state, and encourage them with gentle bottom heat and careful manuring to make quick growth, for after this season there is no time to be lost with young stock. *Calceolarias*, if well established, may be planted out in a turf-pit in poor sandy soil where they can be protected from frost or cold winds, but they must be prepared for this by previously inuring them to full exposure to sun and air whenever the weather will permit. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The weather has been still too unsettled, and the stiff ground too clazy to permit of all being done that is desirable.

Cauliflowers. Forked over the soil among the earliest, which will be later than usual this season, owing to mice and rats having stunged it in as detailed some time ago, a circumstance which precluded their producing good heads. Whilst a lot of fine, strong plants in pots, which if left alone would soon have been showing heads, were thus almost cut down to the surface of the soil, others, smaller and in a similar box, but growing in the soil in which they were sown, were not touched at all. What was if anything more annoying, was the fact that the depredators seemed to have derived no benefit, except amusement, from their work, as though the plants were cut over and nibbled, hardly a bit seemed to have been eaten. The most kind-hearted in such circumstances would be apt to give little mercy in arresting the results of poisoning, trapping, and ferreting. Rough barleymeal, made into a stiff paste with a little water, is much relished by rats, and if mixed with a stick, and laid down with the stick in pieces near their runs, it will soon

be eaten up, and when that is done the same process may be repeated after mixing arsenic with the meal. Care must be taken that no useful animal touch these lumps. We find that mice will seldom touch this mixture, though, on the whole, they are much more easily trapped and poisoned than rats.

Sowed the main crop of Parsnips a week ago; if the ground had permitted would have liked them to have been in about a month earlier. Sowed also the main crop of Onions in good order, and a piece of Horn Carrots. Have been watching for a suitable time to put in the main crops of Carrots, but the ground is not yet so nice as we would like it to be. We generally make two or three main sowings of Carrots; the later ones are sweeter for parbour use, though not so large as the early ones. To have fine Carrots the ground should not only be deeply stirred, but the surface soil should be the poorest, the richest being at the bottom, which will make them run straight without shoudering, &c.

A piece of Newington Kidney Beans in a pit has grown so very strong, that we have had to remove some of the larger leaves to give more room, light, and air to the numerous swelling pods and clusters of bloom. In general this Bean only requires about half the room of such kinds as the Robin's Egg and the Cream-coloured. A row of Robin's Egg, in pots in the front of the Peach-house, just in bloom must be removed to another place soon, or they will shade the Peach-house. A lot in six-inch pots will succeed them; some to be potted in 12-inch pots, if we can find room for them, and others to be set out under glass protection, and covered when necessary. We shall be glad when they are all out of the houses, for, though clean enough now, a miss in watering, &c., after they have borne sometime will be apt to give them company which we would not like to see in the houses, and removing plants after thrips or red spider is seen upon them is apt to leave behind them some of these insects for future breeding. A single pot of Kidney Beans well looked after in ainery or Peach-house may be used as testing plants at times for thrips and red spider. If one appear on the Kidney Bean plant, not only should it be carefully removed, but means should be taken by watch and ward to see that the insects do not take possession of the stationary residents of the house.

FRUIT AND ORNAMENTAL DEPARTMENTS.

In these, in which we have been busy regulating Peaches and Vines, giving the best places for securing good flavour to fine ripening Strawberries, doing a good deal of turring, potting, and propagating, the work with one exception has been so much a repetition and continuance of what was alluded to last week, that in compliance with several requests we will repeat, somewhat as stated long ago, our

Simple Mode of Mercurian Methods for Cucumbers and Melons.

—This involves less labour than the old plan of planting in hills and earthing-up gradually afterwards. We adopted the plan at first from a scarcity of fermenting material, and the desire to lessen labour afterwards. The same mode may be adopted in its general features for a pit heated by dung, as well as for a frame. At present, however, we shall confine our outlines to frames, which are from 5½ to 6 feet in width, 12 inches deep in front, and 18 or 20 inches deep at back, at which size two-light boxes are easily moved, and which, managed as stated, are quite deep enough for Cucumbers and Melons. We have several times stated, that we never work the bulk of the fermenting material sweet enough for such beds, being content if we have a covering of from 6 to 12 inches deep of sweet hot material for the surface. For a substantial bed that is to be pretty early and stand the most of the season, we shall suppose that the bed is to be 3½ feet in height at back, and 3 feet in height in front before the frame is set on it. We mark out the space for the bed, which must be from 30 to 36 inches wider than the frame, so that when the frame is set on, the bed shall be from 15 to 18 inches wider than it at back and front. This first seeming waste will prove ultimate economy and gain.

When the bed has been neatly made, and raised by the roughest and rankest of the hot fermenting material for 2 feet in height, 6 inches of sweetish hot material are placed all over it, and then the bed is continued upwards, back and front, but leaving an open trench of 30 inches in width in the middle, keeping the best and sweetest dung next that trench, and the roughest and rankest to the outside of the bed. When the above height is reached, 3½ feet at back, and 3 feet in front, the frame is set carefully on, and each side of the trench in the bed is well beaten back and front, and a board or slab put down on each side to keep the earth that will be put in the trench from the dung. This trench will be about 30 inches wide, rather more

at the top, and from 15 to 18 inches deep. The glass is kept close for a few days until the heat has risen kindly. Then the trench is filled with suitable soil, the top of the soil being very little above the bottom of the sides of the frame. Some soil is firmly beaten round the sides of the frame inside, to prevent steam entering, and a couple of inches or so of soil is placed on the bed, between the boards of the trench and the sides of the frame, and this covering, if even the upper layer of dung, &c., is pretty sweet, will keep all noxious steam down.

By this plan the following, among other advantages, are secured:—

1st, Not much more than a third of the soil which would be wanted if the whole width of the bed were filled, need be used.

2nd, All the soil necessary is put in at once in the centre of the bed, where good-sized plants are at once inserted, and can be trained to back and front without opening the lights for fresh earthings-up, often of cold soil; and we avoid the necessary moving of the plants and exposure to cold draughts, often followed by hosts of insects, requiring much fumigation with tobacco to eradicate them. Sudden changes in temperature under such circumstances are often the most fruitful sources of an abundant supply of insects.

3rd, If the sides of the frame are well secured, it will need no moving afterwards, if the soil is 12 or 13 inches from the glass at front and 18 inches at back, for the frame will sink as the bed sinks.

4th, The soil being placed as it were in the middle of the bed, there will be no danger of an excessive, burning bottom heat to injure the roots, whilst the soil will be nicely and quickly heated from below and from the sides.

5th, The width of the bed permits of a lining being placed round the box to give a nice healthy atmospheric heat, without unduly increasing the heat at the roots.

6th, Such box-beds have been kept in good order from March to the end of September merely by topping up round the frames with litter and grass, and placing wattled hurdles or leafy branches of trees round the sides of the bed to keep the air and wind from them.

7th, and lastly for the present, such a trench of confined earth will render Melons and Cucumbers less luxuriant and more fruitful than if the roots revelled in the whole width of the bed.

The one exception alluded to had reference to

Caladiums.—These, as last year, were plunged in a nice mild hot-bed of dung and leaves. We noticed for some time many of the leaves more pale than they ought to have been, but did not sufficiently examine them to find the cause, as the temperature, &c., seemed all right. Our young man on taking some out and narrowly examining them, found lots of the stems entered with a small green fly, myriads on myriads of them. They were carefully smoked, and next day were thoroughly syringed with warmish water, and lest any insects should linger in the soil the surface soil was removed, and a fresh surfacing given where fresh potting was not resorted to, and already the leaves are coming of their right and healthy colour. We have as yet been so free of insects this season that we never thought of the *Caladiums* being infested. If they had stood in a house we could scarcely have missed seeing them; but in a pit, without examining them carefully, we could only look at the top surface of the leaves. We have no recollection of seeing *Caladiums* so infested before. The fly seemed a kind that was very easily settled; but the vast number would soon have spoiled any plants.

Lumbago.—We have known but little of the horrors of lumbago since we tried this simple remedy—viz., wearing a band of brown paper round the loins. We will here say nothing as to how the gentle, almost constant, friction produces the desired result; but to every gardener who is a sufferer from this trouble, we would say "Try the remedy."—R. F.

TRADE CATALOGUE RECEIVED.

Louis Van Houtte, Ghent, Belgium.—*Catalogue de Plantes de Serres, et de Plein Air.*

COVENT GARDEN MARKET.—APRIL 7.

THE demand and supply are now well balanced. Grapes and forced Strawberries are both very good, and of both there is a fair supply. Dessert Pears now consist almost exclusively of Easter Burre. Outdoor vegetables of various kinds are abundant; and consignments of

slads from the continent continue ample for all requirements, and arrive in good condition. New Potatoes come in from Malta, the south of France, and Guernsey; those from the first-named place being especially good.

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

FARMING ACCOUNTS (J. Powell).—You cannot have a better account-book than that published by Mr. W. K. Newcomb, Stamford. It is very simple, yet very comprehensive, and he would send it to you by post, free, if you sent him 6s. in postage stamps, with your address.

LARGE WHITE PETUNIA.—Mr. W. Herbert, 22, South Street, Durham, informs us that he can supply this Petunia to "E. S. B. G." if the address is sent.

CHERRIES GRUB-EATEN (Lustria F. Mas).—The grubs which pierce the Cherries in your orchard-house are certainly not the larvae of the Goat Moth, but of some much smaller species, probably a Tortrix. We can suggest no remedy; but the best preventive will be to destroy all the fruit attacked, and to look in the evening for the parent moths.

CHRYSANTHEMUMS (A Constant Reader).—You will find full directions for their culture in "Florist's Flowers." You can have a copy free by post from our office if you enclose five postage stamps with your direction.

COIL-TRAINING VINES (Vines Twisted).—Last year Mr. Fish noticed a vine near Hitchin, in which the Vines were planted in the centre of a span-roofed house, and the Vines twisted in cork-screw fashion until they reached the apex. These Vines grew regularly from the ground to the apex of the roof, and, as was described, came down a little. The intricate twisting of the stems will do no harm to the Vines. Cracking the stems and splitting them would be enervating the twisting too far. The Vines would soon recover from a little splitting here and there. If you were to cover these split parts with a little cowdung and clay, and wrapped this plaster firmly round with a cloth to exclude air and light, the cracks would soon disappear. The object of twisting was no doubt to cause the sap to circulate more regularly through the stem.

GREENHOUSE FLUE IN PARLOUR CHIMNEY.—Having read a reply at page 248 relative to one chimney for two greenhouses, and a flue not answering which communicates with the parlour flue, I write to state that I have a greenhouse at the end of my house. The parlour chimney being next the greenhouse, I took my flue about 3 feet up the parlour chimney, and made an elbow joint, no matter how short, to convey the smoke upwards, and this answers very well. A goose-necked pipe 7 or 8 inches in diameter goes through the wall, and about 6 inches up the chimney. This flue has no effect on the parlour fire, whether in or out. By this plan the flue is not seen, being below the staging. —EDWARD TOWN, North Shields.

THINNING PEACHES ON TREES IN POTS (S. L. T.).—We would advise your leaving from 18 to 24 fruit to ripen, according to the size of the tree. As many more might remain until they were half swelled, then reduce to eighteen for fair-sized trees.

WIRE NETTING FOR PEAS (Idem).—We have often seen wire netting used for Peas. Stakes 4 feet in height were driven into the ground at 6 feet apart, and then the wire was fastened to each side. Very light wire hurdles with feet have been used for the same purpose. We have several times used stout stakes or sticks from 4 to 6 feet apart, and then run strings on each side at a foot from each other.

FLOWER BASKETS ON A LAWN (R. F. S.).—We have no doubt that your proposed plan will answer—namely, filling the two baskets on grass with Pampas Grass in the centre, Gladioli round it, and Farfugium at the outside, with Perilla between that and the Gladioli; but if the place will do for Farfugium, it might be made more gay in summer, even if a shady place, in front of the drawing-room windows. Thus, fill the centre with Gladioli mingled with large-leaved Cannas, then have a mixture of Perilla and Amaranthus melancholicus, and for the outside a broad band of Cloth of Gold Geranium or Mrs. Pollock. The Cloth of Gold will do all the better in the shade, and then you could plant the Pampas Grass in the ground farther off. Even on your first proposed plan we would have a few Pentstemons to fringe the Gladioli, then the Cloth of Gold instead of the Farfugium, and a string of the Viola crumata for the outside line. The worst of Gladioli is that they are temporary flowers, and the Pampas Grass is nothing until late in autumn.

CUCUMBERS THICK-ENDED (C. H. J.).—We would advise you to thin the Cucumbers considerably; and to make sure that the roots seldom touch the top of the tank; it would be well to have some rubble, and then some rough slates below the soil between it and the tank-covering.

CULTURE OF GASTERIAS (A. S.).—The Gasterias belong to the Aloe section of the Lilyworts. They are very nice plants for a succulent collection. They will do well in a house kept from 45 in winter to 60° and more in summer. They flourish best in sandy loam with a little peat and very rotten dry cowdung, and some lime rubbish and broken bricks. Say two parts sandy loam, half a part of cowdung, &c., and half a part of broken bricks and lime rubbish. The chief care they require is to keep them rather dry, almost dry, when in a state of rest in winter. If the pots stand on a damp stone or damp gravel they will absorb enough of moisture in the dark months. All the title-pages and indices your name can be had free by post from our office if you enclose nine post-office stamps with your direction.

CUTTING CAMELLIA FLOWERS (A. B.).—When the flowers are cut by a practised person it does not interfere with the future flowering, for the blooms will only be cut from a part where the subsequent growth will not be interfered with; but when they are taken indiscriminately from every part, then the future growth and flowering are materially affected. When the plants are "cut hard" for their blooms they should be gone over after flowering, and any irregular growths removed or shortened, so as to make the shoots equally thin, and these should be regularly stopped throughout in order to secure their breaking equally at every part, the plants being afterwards placed in heat to secure a regular and free growth.

COLEUS VERSCHAFFELTI FOR BEDDING (F. T. C.).—The soil you employ for potting—viz., two-thirds loam, one-third leaf-mould, and one-sixth silver sand, is good. The soil of the border is also good, providing you enrich it by pointing in a dressing of good loam and well-rotted manure. The top-dressing ought to be 3 inches thick. The plants should be placed 1 foot apart every way, and be well watered in dry weather. You should grow the plants to a good size, and well harden them off before planting out. Do not do this until the second week in June.

FLOWER-BEDS PLANTING (Idem).—Instead of edging the bed of Purple King Verbena with yellow Calceolaria, we should put the Calceolaria in the centre and the Verbena round it; or, if your bed is sufficiently large, have Perilla in the centre, then a band round it of yellow Calceolaria, edging with Purple King Verbena; and it would be better, again, if the Verbena were made a band 2 feet wide, edging it with Coranthium Biebersteinii. Your plan of putting the Verbenas in the centre and edging with yellow Calceolaria is good as to contrast, but the Calceolaria would grow too tall for the Verbena. The bed of Scarlet Geranium, edged with Flower of the Day Geranium, is good, the towers being removed from the latter.

CUTTING IVY (T. J.).—Removing the leaves or cutting-in the Ivy closely will cause the new shoots to come more strongly, and the foliage will be more plentiful and finer. Any time from now until the end of April is a good time to cut Ivy in closely.

TWELVE DISTINCT VERGENAS FOR PLANTING IN CIRCLES (Idem).—If you plant the circles in order we think they would look well. 1, Velvet Cushion; 2, Mrs. Moore; 3, Melindres splendens; 4, Mrs. Hulford; 5, Purple King; 6, Firefly; 7, White Lady; 8, Ariosto Improved; 9, Mrs. Woodroffe; 10, Snowflake; 11, Garibaldi; 12, Spark.

MANURE WATER IN THE EVAPORATING TROUGH OF A VINERY (Subscriber).—Now that the leaves have attained their full size you may keep the troughs filled with manure water from your stock of sheep's dung, soot, and guano. A peck of sheep's dung, the same of soot, and 2 lbs. guano should be diluted with 60 gallons of water. You may instead fill the troughs with manure water of the same strength as that used for watering plants. It acts as a check upon red spider, and invigorates the Vines.

STOPPING PEACH TREES IN POTS (Idem).—If the trees are as large as you wish, and you desire to keep them close and compact, stop the shoots at the fourth or fifth leaf, and at every leaf afterwards, and there will be no necessity to prune in winter; but if you wish the trees to become larger stop them at the fifth leaf, and at the third afterwards, discontinuing the stopping after the fruit has taken its second swelling. You may also allow the shoots to grow without stopping, cutting them back to a triple bud, that is, two fruit buds with a wood bud between them, reducing them to 9 inches if longer, but if not so long and having no triple bud to cut back to, leaving them entire. We recommend the first practice for trees in pots, and the second for those planted out and having plenty of room to grow, whilst the third we do not recommend for trees under glass as bushes or pyramids, but only for trees on trellises and against walls.

MANURE WATER FOR LYCOPODIUMS (Idem).—We do not recommend anything stronger for Lycopodiums than clear water; your plants will be all the better for rain water. Ferns and Lycopodiums do as well, if not better, watered with rain water only, and to some manure water is positively injurious.

CYPERUS ALTERNIFOLIUS VARIETAS (W. E.).—Its usual height is from 9 inches to a foot under good cultivation, but we have seen it as low as 3 inches and as high as 18 inches. If placed in a saucer of water whilst growing, or in summer, the temperature of the water should be the same as that of the house. Our correspondent wishes to have the names of any semi-aquatic plants for a house having a winter minimum temperature of 50°.

GYMNOGRAMMA CHRYSOPHYLLA CULTURE (H. G.).—Your plant does not grow because the temperature is too low. It requires a night temperature of not less than 55° in winter, and a moist atmosphere without the foliage being wetted. Your plant is probably old; such plants never do so well as those which, from being very small, are liberally treated until they become specimens, after which they gradually decline. If you have now a small plant in, say, a 4½-inch pot, we would pot it at once into an eight-inch pot, draining the pot to one-fourth its depth, and using a compost of old cocoa-nut refuse one-half, turfy yellow loam one-fourth, and fibrous brown peat one-fourth, adding one-sixth of silver sand, the whole well mixed and broken with a spade, but not sifted. Pot rather deeply, but not so much so as to cover the crown. The plant should be set in the lightest part of the house, have room on all sides, and be not more than 18 inches from the glass. The soil should be kept moist, but not wet, until the roots are working freely, and the temperature may range from 60° to 65° by night. By day it may be 70° without sun, and from 80° to 85° with it, shade being afforded from 9 a.m. to 4 p.m., when the sky is clear, but when cloudy do not shade at all. No shade will be needed from September to April. The plant must always have the soil moist, but no water should be given until it is really needed, then afford a supply sufficient to show itself through the bottom of the pot. If your plant grow as well as we expect, it will need a shift by the end of July, or at latest by the third week in August, so that the pot may be filled with roots before winter, as it will be in six weeks after potting if a 10-inch pot be given. From this time no more water should be given than is sufficient to prevent the soil becoming dry, and if a sufficiently moist atmosphere be maintained, it will winter safely in a temperature of 60° at night, and occasionally as low as 55° or even 50°, but this degree must be seldom reached. In March you may give a shift into a 15-inch pot, and we think you will have a specimen large enough for anything by August, and it may remain good a year or two longer.

CINERARIAS ATTACKED BY BROWN APHIS (A. Subscriber).—From your description of the insect infesting your Cinerarias we should think it is the brown or black aphid, and if so, it is most injurious, especially to young plants. We find the following destructive to it:—Pour one gallon of boiling water over 4 ozs. of the strongest shag tobacco, cover it over closely and allow it to stand until cool, then add it 1 lb. of soft soap dissolved in a gallon of water, strain through a piece of muslin, and add three gallons of water; there will then be nearly five gallons of liquid. In this, at a temperature of 90°, the plants should be immersed with their heads downwards. A cure will thus be generally effected; if not, repeat the application.

GARDEN DESIGNS (Bob).—It is a great mistake to suppose that variety in the form of the beds contributes to the beauty of a flower garden. The simplest forms correctly planted and well balanced are the most effective.

BELLADONNA LILY (A. Subscriber).—If you turn out the plants next month in a warm sheltered situation, they will flower in the end of September or early in October.

HORTICULTURAL GLASS (Miss H.).—We do not know any of the manufacturers at Liverpool, Sunderland, or Durham. You will find their names in the County Directory.

PLUNGING-MATERIAL (W. A. O.).—The safest material for plunging pots in is sand or coal ashes. Sawdust from old dried hard wood will do very well; but all fresh sawdust from green wood has a tendency to clog up the drainage-holes in the bottom of the pot, and is also liable to become a breeding-place for fungi and conferva.

SEEDS (Ignoramus, Dublin).—They are the seeds of some Pinus or Abies, but we cannot name plants from seeds.

DESTROYING RED SPIDER (A. Constant Reader).—Yours appears a very bad case, and we recommend the following remedial measures:—1st, Wash the glass inside with clear water. 2nd, Wash the woodwork with a strong solution of soft soap, 8 ozs. to the gallon of boiling water, using it as hot as possible, washing it clean off and all the dirt with a flannel, but keeping the soap from the glass. 3rd, Whitewash the walls with two-thirds lime, one-third flowers of sulphur, brought to the consistency of whitewash by adding a solution of 4 ozs. of soft soap in a gallon of boiling water. 4th, Keep the evaporating-troughs full, and the floors sprinkled twice or three daily with guano water, made by dissolving 2 ozs. of guano to the gallon of water. 5th, Syringe the plants vigorously twice daily, morning and at shutting-up, with water of the temperature of the house. If you do this, and still have red spider at the end of ten days, then, 6th, Mix sulphur to the consistency of thick paint with the soft soap solution previously named, and apply this to the pipes, heated to 160°, shutting-up the house quite close, and coating the pipes from one end to the other. Put on the sulphur wet, and when done commence syringing gently with water at 120° until you fill the house with steam. 7th, Syringe the plants in the morning with soft water, made by putting a peck of soot in a tub, pouring over the soot 30 gallons of water, and stirring it up until it sink. Allow the whole to stand until clear, and use the clear water for syringing the plants morning and evening, continuing to moisten the floors with guano water as before, and within a week of the first coating of the pipes with sulphur repeat the process. The only danger you have to fear is not giving air by the time the sun shines powerfully on the foliage whilst it is wet. We should think that the houses have been kept as dry as dry stoves were in former times, to bring about the state of affairs described in your letter. We agree with you, that the fact of the houses not having been washed and thoroughly cleaned for a long time has been favourable to insect life; thorough cleanliness is the great safeguard against disease and vermin. The two inches of soot over the crocks at the bottom of the Strawberry pots is one-eighth in excess; that and the frequent applications of manure water in winter fully account for there being few roots in the pots of fruiting Strawberries. Liquid manure cannot benefit plants when at rest.

NAMES OF PLANTS (G. H. A.).—The leaf sent is that of some Caladium. (A. Nappan).—We believe it to be only a fragment of a Moss, Hypnum proliferum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 7th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ROUP IN POULTRY.

We have felt thankful for months that we have had no pest among our poultry; but we cannot help remembering what we suffered years ago, and the recollection of it gives us hope that the sore visitation under which we are now lying, may in like manner either yield to remedies, or disappear before precautions.

When first poultry was imported in quantities from Holland, almost every bird within a week of its arrival sickened with roup of the most virulent kind, and carried it wherever it went. We have a painful recollection of turning down two Polands bought out of a Dutch lot, at a small farm where we had about a hundred good sound fowls. We heard of their being sick in about five days, in a fortnight all in the yard were so. Nearly all died. The place was whitewashed, the house new gravelled; but it was long before we got rid of the infection. Some amateurs will recollect at the first show at the Surrey Zoological Gardens, the rows of empty pens labelled "Removed on account of disease." It was in those days one of the duties of the judges to cause diseased birds to be removed. Those exhibitors who thoroughly understood the question, used to have

their fowls put as far as possible from the Hamburgs and Polands. Roup was considered to be the natural state of both these breeds. The poultry mania, as it was then called, had just sprung into existence in England. It had always existed in Holland, and when the Dutch found there was a ready sale here for anything they could send over in the way of fancy fowls, they loaded every steamer with huge basketsful of them. They were on deck, and in bad weather were closely covered with tarpauling; they had no food during the voyage; many died: the rest were landed reeking with steam, half starved, and then exposed to cold draughts and bitter winds on quays. After fasting many hours they were allowed to eat any quantity of any sort of food, and worse than all, to drink an unlimited quantity of water. Disease always, and death often, followed. So long as the loss was confined to the buyer in this country, no alteration took place; the fowls were still sent as before, but as soon as purchasers became wary, and only those parcels could find a market which were carefully packed and tended during the passage, then an alteration took place, and birds were properly sent over. From this time the disease that had raged fatally, and that had been carried wherever one of the birds went, began to decrease, and now for years past our "pest" has been a thing of the past, unknown to many, and dreaded by none. Among the fifteen hundred or two thousand pens at the Birmingham Show, there is never a thoroughly roupy pen to be seen. This is the result of a little painstaking.

RAILWAY CHARGES FOR POULTRY.

SINCE we published the last list the following subscriptions have been received towards defraying the expenses of presenting a Memorial to the Directors of the railways:—

Table listing names and amounts of subscribers to railway charges, including Mr. J. D. Newsome, Mr. G. H. Roberts, Mr. Stevens, etc.

PROFITABLE POULTRY.

YOUR readers may like to know the results of a twelvemonth's experience as to the profit of keeping poultry, such as I have found it. I began at the end of March last year (after building a weather-board fowl-house, and bringing together the needful apparatus, with a lot of poultry, mostly barn-door fowls, including, however, three Spanish hens and a cock of the same breed. There have been from eight to twelve hens and two cocks (Spanish) during the year, one of the latter of my own breeding; also, I reared a quantity of Ducks and chickens. The balance sheet is as follows:—

Balance sheet table with columns for EXPENSES and RECEIPTS, listing items like Fowl-house and apparatus, Poultry and Ducks, Food, Total expenses, and Deduct receipts, ending with a Balance of 3 18 2.

If the cost of the fowl-house be not reckoned, neither the actual stock of poultry (two cocks, twelve hens, and three ducks), which we value at £1 14s., not reckoning them as fancy fowls, and only the actual cost of food be taken into account, there will appear a gain of £3 9s. 10d. on the year.

I should add, that my poultry are not confined. They lay and roost in the fowl-house, where they can be shut up at pleasure, otherwise they have an almost unlimited range of grass land, with various dust and manure heaps to amuse themselves with. They are fed on barley, Indian corn, and barleymeal.—B. & W.

WIGTON POULTRY AND PIGEON EXHIBITION.

IT gives us much pleasure to report that the Show of this year, held on the 5th and 6th inst., far exceeded any of those preceding it, the entries proving generally in excess of the number at former meetings, whilst the perfection of the specimens throughout showed an advance apparent to every one. We can, however, state that the receipts for admission will tell unfavourably when tested by comparison with past years.

It has always been arranged to hold the Wigton Poultry Show at the time of the Wigton Spring Cattle Fair, as at that time the town is unusually full of visitors engaged in business transactions, and they mostly become visitors to the Poultry Show. This year, however, in accordance with the order of the Privy Council, no cattle could be sent to Wigton; and the paucity of attendance at the Horse Fair, only, at once told how much both the local Railway Company and also the Exhibition Committee would inevitably be sufferers. We are glad to say, however, that, notwithstanding the Poultry Committee look forward to a more happy state of things, and express themselves as quite too plucky to think of abandoning their Show through one bad year. No doubt the cattle plague restrictions will tell most unfavourably throughout the whole country, inasmuch as those poultry shows in any way connected with agricultural meetings.

But to the Show itself. The large increase of entries this year proved unfavourable to the display of the poultry exhibited, as it necessitated the Pigeons being shown in a private room in connection with the Odd Fellows' Hall; and in the Hall itself this greater number of poultry pens, in a space lighted only from one side, caused the specimens in many portions of the Show to be very obscure. In all such cases it is the prudent course for committees to place the darkest-coloured varieties in the lightest portion of the exhibition, as the lighter-plumaged birds show to less disadvantage so circumstanced than their more sable brethren.

The Game fowls generally were very good; but as the breeding season is now somewhat advanced, the birds in addition we meet with in winter was very rarely attainable—a feature on which, in all varieties of Game fowls, so much depends. Referring to the awards, it will be seen that many of our best-known breeders competed. The Spanish class was by far the best ever yet seen at Wigton; and the Grey Dorkings shown by Messrs. Rowlandson and Robinson won their

laurels in a very severe competition. In Cochons there was only one general class for all colours, the Buffs in both instances proving the winners. The first-prize birds belonging to Mr. Henry Tomlinson, of Birmingham, were a truly magnificent pair, of a decidedly clear bright buff colour, and shown in such perfect condition that the pen proved one of the lions of the Show, and, as being marked at the low price of £10 only, would most probably change hands. Messrs. Bowman & Fearon's second-prize birds were also unusually good. The Golden-spangled Hamburgs were a very excellent class, perhaps one of the best in the whole Show, but unfortunately laboured under the disadvantage of being placed in the darkest pens in the room. Messrs. Beldon, Robinson, Wood, and Henderson were the principal competitors. The Silver-spangled Hamburgs stood next in order in the prize schedule, and, though few in numbers, these shown were of an unusual merit; it is only a very rare occurrence, in fact, that such good specimens are shown at even our largest exhibitions.

We regret to record, however, a circumstance that here came to light that deserves animadversion. After the prizes were awarded, but before the admission of the public, it was discovered that the hen in the first-prize pen of Silver-spangled Hamburgs, the property of Mr. A. K. Wood, of Burnside, Kendal, had, by some one or other, been most cruelly tampered with. The extreme point of a common sewing-needle was noticed as slightly protruding near the peak of the comb, so little as to be scarcely discernible except when under pressure, and, after some considerable difficulty, it was finally extracted with pincers by the Judge in the presence of some half dozen or more of the Committee. It had evidently been forced through almost the whole length of the hen's comb, and the portion of the needle called the eye had been broken off abruptly. It is scarcely needful to remark on the evident injustice of such practices, much less to insist on the gross barbarity of thus treating an unoffending bird, for its sufferings must have been severely conceivable. The exposure resulted in the Judge at once disqualifying the pen altogether, Messrs. Beldon and Robinson taking the Society's premiums. On looking at the disqualified pen a few hours afterwards, the hen's comb slightly drooped over to the side on which the needle had been extracted.

The Golden-pencilled Hamburgs were superior to the Silver-pencilled Hamburgs, but it is getting too late in the season for exhibiting adult Pencilled Hamburgs. The Any other variety class of fowls was peculiarly good. The Game Bantams were scarcely equal to the ordinary run, but some excellent Sebrights and Japanese were shown.

In Ducks the extra class was a perfect treat to visitors; Mandarins, Carolina Ducks, Teal, Grey Gull, and Wild Ducks being shown in perfection of plumage. This class proved the eye-catcher of attraction in the Show. The Romans were without exception all of them faulty, the Ducks having dark slaty bills. In the Aylesburys, also, many of the specimens shown were much spotted with black on the bills—an insuperable objection, and one against which exhibitors cannot so carefully provide.

The Pigeons were a very superior collection, the Blue Owls, the Short-faced Tumblers, Nans, Turbits, and the whole of the Extra variety class being especially worthy of the closest examination.

It has always been the custom at Wigton to give prizes for dishes of eggs, to be shown in dozens, and a capital entry generally ensues. It would be well, however, for exhibitors to pay some little attention to matching the different lots, so far as they can, for colour and general appearance, as also to avoid sending deformed eggs, however large, as weight is not the only requisite expected. The heaviest hens' eggs in a dozen, weigh d 2 lbs.; the heaviest Ducks' eggs, 2 lbs. 7 ozs.

The weather proved remarkably fine and spring-like, and the visitors appeared much interested in the proceedings. Before the time for holding another meeting comes round, we sincerely hope the drawback we at first alluded to will have ceased to exist, and that the Wigton Show will be again available to us many sight-seers as formerly.

GAME (Black-breasted and other Reds).—First, J. Bell, Wigton. Second, H. Beldon, Goat-chook.

GAME, White and Piles.—First, J. Brough, Carlisle. Second, W. Todd, Waverbridge.

GAME, Duckwing and other Greys, Blacks, and Blues.—First, Messrs. Easton & Mabon, Jedburgh. Second, J. Brough.

GAME, FINEST (Any colour).—First, J. Harris, Wigton. Second, J. H. Wilson, St. Bees. Highly Commended, T. Manduell, Aikhead; J. Brough.

SPANISH.—First, H. Beldon. Second, J. H. Wilson. Highly Commended, H. Beldon; J. Harrison, Burnside.

DORKINGS.—First, J. Rowlandson, Hawkshead. Second, J. Robinson, Garstang. Highly Commended, Messrs. Gunson & Jackson, Whitcaven; J. L. Jackson, Bust Ewes.

COCHON CHINA. Any variety.—First, H. Tomlinson, Birmingham. Second, Messrs. Bowman & Fearon, Whitcaven. Commended, Miss Aszilion, The Hollins, H. Beldon.

HAMBURGH Golden-spangled.—First, H. Beldon. Second, J. Robinson, Highly Commended, A. K. Wood, Burnside, Kendal; W. Henderson, Wigton.

HAMBURGH (Silver-spangled).—First, H. Beldon. Second, J. Robinson, Hamburgh. Gold and Silver-pencilled.—First, R. Burrow, Longtown (Golden-pencilled). Second, J. Robinson (Silver-pencilled). Highly Commended, R. Burrow. Commended, A. K. Wood.

ANY OTHER VARIETY.—First and Second, H. Beldon (Silver-spangled and Golden-spangled Polands). Highly Commended, G. H. Roberts, Preston (Dark Brahma); R. S. Jessop, Hull (Black Polish).

GAME BANTAMS (Black-breasted and other Reds).—First, C. Ashworth, Halifax. Second, I. Monkhouse, Kendal. Highly Commended, H. Beldon; T. Armstrong, Wigton. Commended, T. C. Harrison, Hull; T. Kenyon, Blackburn.

GAME BANTAMS (Any other colour).—First, Miss Aglionby. Second, R. Tate, Leeds. Highly Commended, S. H. Stot, Rochdale.
BANTAMS (Any other variety).—First, R. Burrow (Gold-laced). Second, H. Beldon (Japanese). Highly Commended, J. R. Jessop (Black and White); S. & R. Ashton, Mottram.
DUCKS (Aylesbury).—First, M. Birket, Brown Rigg, Ainstable. Second, T. Paterson, Melrose.
DUCKS (Rouen).—First and Second, G. Hetherington, Curthwaite.
DUCKS (Any other variety).—First, T. C. Harrison (Mandarin). Second, J. R. Jessop (Carolina). Highly Commended, H. Beldon (Grey Cull); T. Dyson, Halifax (Teal). Commended, T. White, Greenwood (Wild Ducks); E. Young, Wigton (Wild Ducks).

PIGEONS.

CARRIERS.—First, H. Yardley, Birmingham. Second, Withheld.
TUMBLERS.—First, H. Yardley. Second, T. Long, Wigton. Highly Commended, H. Beldon; J. Fielding, Rochdale.
POWERS.—First and Second, H. Yardley (White and Red).
FANTAIS.—First and Second, H. Yardley. Commended, J. R. Jessop.
JACOBS.—First, R. Thompson, Moresdale Hall. Second, H. Beldon.
NUSS.—First, T. Paterson, jun., Melrose. Second, H. Yardley.
BARRS.—First, H. Beldon. Second, R. Thompson. Commended, H. Yardley.
TURBITS.—First and Second, H. Yardley. Highly Commended, R. Thompson. Commended, H. Beldon.
OWLS.—First, J. Fielding. Second, W. Towerson, Egremont. Commended, H. Yardley.
TRUMPETERS.—First and Second, I. Monkhouse, Kendal.
ANY OTHER VARIETY.—First, H. Beldon (Red Magpies). Second, W. Towerson (Black Magpies). Highly Commended, H. Yardley (Spots); J. R. Jessop (Blue Swallows). Commended, H. Yardley (Black Magpies and Isabels).

EXTRA PRIZE.—*Game Cock*.—First, W. Stobbart, Middleton-one-Row. Second, H. Beldon. Third, J. Fletcher, Stoneclough. Highly Commended, R. Pickering, Carlisle. *Cocker*.—First, J. Geldard, Kendal. Second, J. Fletcher. Third, T. Mandell, Aikhead. Highly Commended, T. Robinson, Wigton.
COUNTY PRIZE.—*Game Cock*.—First, W. James, Bolton Gate. Second, Withheld. *Cocker*.—First, T. Manduell. Second, J. M. Armstrong. Highly Commended, T. Robinson; J. Wallas, Highmoor.
HEN EGGS (One Dozen).—First, A. Henderson, West Wood-side (Cochin-China). Second, T. L. Jackson, Bust Ewes (Dorking). Third, M. E. Hopkirk, Broughhead (Spanish and Dorking). Highly Commended, Mrs. Bowman, Westfield. Commended, H. Beldon (Spanish); J. H. Wilson, St. Bees (Game and Spanish).
DUCK EGGS (One Dozen).—First, Miss Barthwick, Flimby (Rouen). Second, J. Rooke, Rosley. Highly Commended, J. Ross, Beckellien (Rouen). Messrs. Gunson & Jefferson, Whitehaven.
SELLING CLASS.—First, J. H. Roberts, Preston (Dark Brahma). Second, R. Burrow, Longtown (Golden-pencilled). Commended, Messrs. Bowman and Fearon (Black Spanish).

The Judge was Edward Hewitt, Esq., of Sparkbrook, Birmingham.

WHY PREFER WHITE PLUMAGE?

In the Number of March 13th, Mr. Brent says—"I am a great advocate for white plumage, it keep the birds warm in winter, and cool in summer." Is this true? As a winter covering I have no doubt white is best; but as a summer plumage, is not a dark colour better? If not, how is it that so many animals and birds become dark in the summer? The negro can stand a tropical heat where a white man cannot, and I know that white pigs blister in the sun, while dark ones do not.—JOHN WILSON.

[In reply to Mr. John Wilson's note, I beg to say my reason for believing that white plumage is best for resisting the changes of temperature, is because white reflects heat. Thus, if you lay your hand on a white surface on which the sun has been shining, you will find it comparatively cool; if, on the contrary, you were to place your hand on a black body also exposed to the sun, you would feel it very hot. I had two goats, one white and the other black. The white one seemed quite comfortable in the sun, when the black would pant and seem so much distressed by the heat, that I had often to move her into the shade. Drive a black and a white horse together on a hot sunny day; the white will remain tolerably cool, when the black is all in a lather. I think white poultry very pretty, and quite as hardy as coloured. Lastly, white feathers are more valuable for feather beds. These are my reasons for advocating and keeping white poultry.—B. P. BRENT.

P.S.—According to Mr. Darwin's theory it is quite right that birds should be white in winter, and dark in summer, because then they would assimilate to their habitation, and be less easily seen by their enemies.]

THE VARIOUS CARRIER PIGEONS.

In reply to your correspondent, Mr. W. Townshend, I will as shortly as I can explain the differences.

The English Carrier is a large, slender, handsome-made bird, one of high caste or high fancy, and bred to a standard of

properties; long beak, straight head, and a large wattle; colour usually black or dun.

The Horseman is a similar bird, but coarser, less elegant in shape, with a crooked bill, and is generally black or white.

The Dragon is smaller, shorter, and has less wattle, being crossed with the Tumbler, and it was much used for homing before the introduction of the Antwerp.

The Antwerp was a variety of flying Pigeon formerly imported from Antwerp, and is probably a cross between Tumblers and the Dove-house or Rocks.

These have been superseded by the Belgian Carriers, which are now considered the very best of homing birds. The Belgians train them to come home from a distance of 500 or 600 miles. They are supposed to have originated in crosses between the Owl Pigeon, the Volant, and Le Pigeon Canus; the Volant being the same as the old Antwerp, and the Canus very much like a Barb.

Any one of the above being of a blue colour, would of necessity be a "Blue Carrier."—B. P. BRENT.

BEEES IN THE HOLY LAND.

I AM desirous of correcting the mistaken impression respecting the Ligurian species of honey bee being indigenous in the Holy Land which is conveyed by the extract from "Tristram's Journal of Travels in Palestine," which appeared in page 266. The fact is, that the native bee of Syria is an entirely different species from that of Italy, being identical, or nearly so, with the Egyptian bee, *Apis fasciata* of Latricle. This species (like *Apis ligustica*), has bright yellow bands on the abdomen, but is of smaller size, and makes smaller cells than either *A. mellifica* or *A. ligustica*, being, moreover, distinguishable from the latter by the colour of its pubescence, which is silvery white instead of yellow. Its habits and natural history are correctly described in the extract referred to as being very similar to those of the common honey bee, but it has no yellow bands on the thorax, nor are its antennae of remarkable length.—A DEVONSHIRE BEE-KEEPER.

A "HUNGER SWARM."

You know the proverb about "a swarm of bees in May." What do you say to a swarm of bees in March? A neighbour of mine had a swarm to-day (March 29th), about half-past one o'clock. It flew to my apiary, and simultaneously commenced entering four or five hives out of the twelve that it contains. Noticing a larger number of bees at one hive than at any of the others, I went up to it, and on the stand I saw and caught the queen in my hand. I was showing her to my gardener, when on opening my hand too far she took wing and flew away. Some fighting took place, and while I stood watching them, I saw several bees dead or dying on the ground. Some few were literally pinned together by their stings, and in the expiring effort to disengage themselves, drew their intestines out with the sting.

Do you apprehend any mischief resulting to my hives from this unexpected and unseasonable addition to them? I hope they are sufficiently well provisioned to support the surplus population thus forced upon them. The hive from which the swarm issued is about 30 or 40 yards from my apiary.

I shall be glad to hear from you or from any of your correspondents, whether it is on record that a swarm of bees has ever taken place in England on the 29th of March; or whether any has issued earlier than this. An answer in "our Journal" will much oblige.—T. R. DRAKE, *Fittleworth Vicarage, Petoorth.*

This was not what is properly called a swarm, but was, doubtless, a complete exodus of the whole of the inhabitants of the hive. Many similar instances are on record, and they are generally attributed to the approach of famine at a time when the bees are unable to find sufficient food to maintain themselves. For this reason they are called by the Germans "hunger swarms."]

BEE DYSENTERY.

As so much was said in your columns a short time since upon dysentery, and so many were inquiring for a remedy, I fear from the silence which has prevailed of late upon the subject that those whose bees were suffering from the malady have

given up in despair, thinking there is no remedy. I am, however, confident that the disease may be cured, unless indeed the bees are so far prostrated as to be unable to take the food given them; and if any practical bee-master, whose bees may be afflicted with it, will send to the under-mentioned address I will forward him the remedy gratis.—G. TURNLOW, *Buckland, Dover.*

FEEDING AND SHIFTING BEES.

The following is a description of the mode in which I feed my bees. It is, in my opinion, the best plan I have ever heard of, but whether it is new or old I cannot say. I make my floorboard 1 1/2 inch thick, and then cut out a piece 3 inches wide from the back to the centre. A sheet of tin is tacked under the opening for the drawer to slide on; the drawer is made of deal to fit the vacant space cut in the floorboard, but must not fit too tightly, as the syrup makes it swell. The drawer is of the same thickness as the floorboard, with three grooves cut in it 1 inch deep and half an inch wide, the partitions between the grooves serving for the bees to stand on whilst taking their food. The way in which I move my bees a short distance, say 15 or 20 yards, is by shifting stand and all 1 or 2 yards each day until I bring them to the place where I want them.—A BRUCE BEE-KEEPER.

[We prefer feeding bees at the top of the hive.]

COMPARATIVE LONGEVITY OF THE LIGURIAN AND BLACK BEE.

A NOTE of my experience as to the comparative longevity of Ligurian and black bees may not be without interest at this time. In May, last year, I made several artificial swarms, being desirous of increasing the Ligurian strength of my apiary. This I accomplished by two or three modes, all being equally successful and substantially the same in principle. One of these artificial swarms was formed by transposing an empty Woodbury hive, containing three frames of Ligurian comb and brood, with a strong stock of black bees. Of course I expected the bees would raise from the brood a queen, which would be a hybrid or, possibly, pure, as I have one stock formed thus which has produced a perfectly pure queen. On examining the box a short time afterwards I found that the old black queen had escaped into or had joined the new swarm, but it was not convenient for me to do anything more with it, so it stood as it was. The Ligurian brood hatched from the frames duly made its appearance, and some of these bees have continued until the present time. Many of them were visible during the mild weather in January, but they now seem to have reached the limit of their existence, as only a few stragglers, very feeble and attenuated by age, remain. This would give an average age of about eight months, which is double the age that I have ever seen black bees attain by a similar test, which I have frequently had occasion to witness.

I am glad to say that the year opens very favourably, in an apian sense, with me. Last season I managed, from four stocks—one pure Ligurian, one hybrid, one black stock, and one black stock too weak to aid operations in any way, to obtain in all four absolutely pure Ligurian, six hybrid of various degrees, and four black stocks. Of these, one hybrid perished from a casualty last week, another I have given to a friend, and the rest remain healthy and strong, and hard at work, whenever weather permits. I have no doubt that I might have considerably increased the Ligurian element last season, but various circumstances prevented my being able to devote so much time to them as I could have wished. I hope this year to have twelve pure Ligurian hives in my apiary, and then I shall rest contented.

I first saw pollen-gathering in the second week of January this year. The cold weather of course suspended it, but it is now (March 23rd) general on fine days. On February 18th, I noticed several chrysalides or pupæ turned out of two hives, evidencing that breeding had commenced in them at an abnormally early period.—G. F. B., *Spalding.*

OUR LETTER BOX.

SILVER-GRAY DORRINGS (*Kate*).—A cock with the feathers you enclosed cannot be a Silver-Gray Dorking.

CHICKENS DYING (*Notice*).—We should attribute much of your want of success in rearing to the use of Indian meal. It is cloying and fattening, but deficient in the necessary properties for making bone and muscle. We think it very bad chicken food. Your mode of feeding is very bad; the chickens get their mouths full of your paste and cannot get rid of it. Then they try to pick up sand or grit as a digester, and that sticks, and makes the hard substance in the beak. Take away the food. Let them be fed often with chopped eggs, bread and milk, oatmeal slaked with milk, scraps of fat chopped fine, and a little bread and ale, some pieces of potato for a change; but it is bad food. If the hen is in a confined room or house move her out, but keep her under the coop. Recollect, chickens want to be fed very often, and to pick up morsels at a time, and it is well for them to have to seek them. It is against nature for them to take a mouthful, and if the food is sticky they cannot get rid of it. For this reason the hen must also be dry-fed. Your paste has been the cause of all your failures. Even the meal you mix should be dry enough to break and scatter when it is thrown down. If you will adopt this plan you will save your chickens; but you must free their mouths from all the stuff that has stuck to them.

YOLKLESS EGGS (*C. B.*).—It is no more than a derangement of the laying organs, and will not continue. A dose of castor oil will often cure it. If the hens are debarred from green food out than some large sals of growing grass, at the present time of year a most valuable poultry food and medicine.

FACE OF SPANISH COCK (*Stourbridge*).—Spanish cocks are oftentimes inconvenienced by the excessive development of their beauties, as in this instance; but although the eye may be invisible, it is seldom entirely closed. There is only one way of keeping the eyes unclosed, which is by strapping back the overlapping lids with narrow strips of some adhesive plaster. We have had many years' experience of Spanish, and have never found this operation necessary.

SHELL-LESS EGGS (*A. J. Z.*).—Discontinue feeding on flesh; you will never have really healthy fowls while you feed on meat. Instead of chalk throw down some bricklayer's rubbish. Give them, if they are in confinement, some growing grass cut in heavy sals with plenty of fresh earth to them. Eating the eggs is far more serious than laying soft ones. Put some hard composition eggs in their nest. The soft eggs and the desire to eat them would imply temporary want of health and derangement of secretions; but as the eggs are shell-less, and as the first desire to eat them is undoubtedly from a desire to obtain that which will make shell, we cannot help thinking that they do not possess material for forming it. Road grit or scrapings are excellent for poultry-houses and runs.

CALL DUCKS WITH ROSEN DUCKS (*H. A. E.*).—We think, except in extraordinary cases, Call Ducks and Rosens may be kept in the same yard without fear of intermixture. They cannot be kept with Wild Ducks or any of the smaller breeds.

TURKEYS (*A. B.*).—The Norfolk and the Cambridge are the best breeds for the table. Eggs are constantly advertised in our columns.

GAME COCK WITH BLINDED EYE (*F. W. J.*). The accidental loss of an eye, for instance, if it has been out fighting, is not a disqualification, not even a disadvantage; but a sightless eye is a disqualification. We mean an eye presenting its full volume, but dull and grey-coloured.

CREOLE AND CUCKOO FOWLS (*J. R.*).—IT IS EASY to buy Cuckoo fowls; but we do not know where there are any Cuckoo Creoles.

VARIOUS (*A. Bojiner*).—For Brahma Podras you must write to some one who advertises them in our columns, stating what is your object. Feeding in troughs or not is merely a matter of opinion. We always use troughs, as being less liable to waste. We have no objection to giving rain water to fowls if it is quite sweet and fresh. If taken from a water cask it seldom is sweet, and if not sweet it is objectionable.

IMPROVED FRAME HIVES.—"SIBERT-IN-THE-WOLD" writes to correct an error in the punctuation of the last paragraph in page 255, which should read as follows:—"The size of my boxes is also different from any other that I know of, being always of the same depth—viz., 10 inches, but, of course, varying in width, as constructed to contain from four to ten frames; as the locality in which I reside is by no means favourable for bee-keeping (the wolds of east Kent being about the same in character as the wolds in other parts of the kingdom—viz., high, windy, and open), my boxes are usually made with eight frames."

TROUT (*L. J. B.*).—As your stream flows freely there is no fear that the trout will not be supplied with food. They feed on flies, gnats, grubs, small water molluscs, and these are supplied abundantly naturally. If you place any dead animal body in the water, it will attract insects, and, the gentles bred in it would not be neglected by the fish.

QUERY (*W. W. Burton-on-Trent*).—You had better write to the secretary of the club.

ZINC IN A CHURN (*G. B.*).—If kept perfectly bright inside no injury would arise; but if it became oxidised (which in the angles of a barrel churn it would), the acid of the cream would dissolve some, forming a lactate of zinc, the medical properties of which we do not know. There is no material for a churn so eligible as wood.

TITMICE (*A. Subscriber*).—You must either shoot these bee-vampires or trap them. A common steel trap of the size used for catching mice, and baited with a bit of suet, will entrap them. There is another trap made by heading a hazel rod, a loop of string, and a peg baited at one end with suet, which also secures them. It can scarcely be made intelligible without a drawing, but most boys know how to construct it.

POULTRY MARKET.—APRIL 9.

We shall have little change to note for the next few weeks. Prices will probably remain good, with little variation, until the advancing season increases the supply of poultry.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 57.3°; and its night temperature 36.0°. The greatest heat was 77°, on the 19th, 1854; and the lowest cold 22°, on the 17th, 1847. The greatest fall of rain was 0.52 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

MANETTI STOCKS FOR ROSES.

FTEEN lately I have intended to add a few remarks of my own on the much-ventilated subject of Manetti stocks, and the letter of a "COUNTRY CURATE" in your impression

of the 3rd inst. has induced me to send you the following, though I am afraid, as so much has been said by such able rosarians as Mr. Kent, Mr. Radclyffe, and others, I shall not be able to add much that is new.

First, I will begin by replying to "COUNTRY CURATE'S" question as to the form of Rose-growing best suited to his soil. I apprehend that his soil may be said to be a tenacious loam with a good deal of humus in it, and very likely, from its retaining the moisture a good deal in winter (as appears to be the case from the manner in which many of his Manetti cuttings perish), there will be a considerable amount of humic and geic acid in the soil. The nature of the subsoil, also, leads me to suppose that there is in the gravel a considerable quantity of iron, which is very injurious to the roots of all fruit trees, and of Roses also. Manetti stocks being more fibrous-rooted, and less inclined to produce tap roots than the Briar, their roots will not be so liable to penetrate into the subsoil as those of the Dog Rose. The length of shoot that "COUNTRY CURATE'S" ROSES have made in one year from the bud, would lead me to think that the best form in which he could grow Roses on the Manetti stock would be as dwarf pillar Roses, encouraging a strong, or two or three strong, shoots from the bottom of the plant each year, and cutting away all old wood when it was more than two years old. He will not obtain so great a head or, perhaps, so many blooms in this way, but he will have the satisfaction of finding his blooms far finer than if he encouraged the plants to make bushy heads, and also that the strength of the shoots from the ground will each year materially increase. I have found, too, by experience, that the young vigorous shoots, when well ripened, are far more hardy than the old wood. I have suffered severely this year from a frost on the 1st of March; all my Roses up to that time had been growing, many of the young shoots expanding leaves. On the evening of the 28th of February a sleety rain was followed by 2 or 3 inches of snow, and in the middle of the night a severe frost came on, the thermometer, 4 feet from the ground, falling 12° between eleven o'clock at night and seven the next morning, when it stood at 15° Fahrenheit. This was a most severe ordeal for the Roses. Coming after such a warm winter, the consequence was every young shoot that had pushed was cut back, and in many instances the old wood has suffered too, but hardly any of the younger and more vigorous shoots. Another advantage of continually cutting away old wood and inducing shoots from

the base is, that the growth is so much stronger, that it is thick enough to supply a sufficiency of sap to obtain more perfect show Roses on one stem than by any other means, and it does not require the same tying up and support as weaker shoots do. I always allow the shoots to grow in the autumn as long as they choose, having had some General Jacquemont on four-year-old plants with from 10 to 11½ feet shoots from the base in one autumn; these I shorten and tie up before winter, but I do not finish final pruning till March or the beginning of April, according to season. Of course if quantity and not quality of bloom is the object desired, then more of the old stems must be kept in, and the plant trained in bush or pyramidal fashion.

Now a few words as to the propagation of Manetti. One of the chief points is to choose the right sort of wood for cuttings; for this purpose it is better to devote a spare corner to some old plants, which may be allowed to grow unrestricted to furnish strong shoots. The longer, straighter, and cleaner the shoots for cuttings the better. Cut them into lengths of from 9 inches to a foot; pick out all the bottom eyes, and cut the shoot square across at a joint. Plant them about 4 or 5 inches deep, and earth them up in rows, like Potatoes, to within 2 or 3 inches from the top. The cuttings are best put in from the second week in August to the last week in September, and should be watered for the first three or four weeks if the weather is very dry. The cuttings may be transplanted in the following autumn, and planted in the same way in rows about 3 feet apart and 1 foot from plant to plant; but some of the most forward of the cuttings will be fit for budding on the next spring where they were struck. I need hardly add that the best way of budding is to insert the bud in the stem which formed the cutting, by levelling down the ridge. I do not agree with "COUNTRY CURATE" in ever thinking it a good plan to earth up the plants again after they are budded; it is better to put a little clean straw on each side of the rows to protect them in the winter, mulching the ground with manure between. If "COUNTRY CURATE" wishes to have the buds push, so as to make plants to transplant the same autumn, he may do so by budding in July as soon as he can obtain good buds. As the part of the Manetti on which the bud is inserted is always covered with soil till the time of budding, the stem is kept moist, and is not hardened by the sun, so that the bark will almost always separate easily for the insertion of the bud. I have known stocks bud very well in the first week in July.

Next, with respect to planting Roses on the Manetti stock. Many persons used to fall by not burying the bud, but now it is universally allowed that the collar of the Rose should be covered with soil, and many persons err in the opposite extreme, and plant the union of the scion and stock from 6 to 8 inches below the surface of the ground. I have now grown Roses on the Manetti stock for twelve or thirteen years, and my rule has always been to plant about 2 inches below the surface; by this means I have never been troubled with Manetti suckers, or rather shoots; for the Manetti stock, in spite of what

the late lamented Mr. Donald Beaton used to say, never makes root suckers, and the roots of the Manetti are not buried too deeply so as to be away from the influence of the sun and air. Two inches also are quite deep enough to induce the Rose to push out roots of its own.

I cannot agree with Mr. Robson, that if the Manetti stock is merely a medium to obtain Roses on their own roots, the sooner it is done away with the better, because by budding on a Manetti and then planting, we obtain a fine bed of Roses two or three years sooner than by plants from cuttings. Moreover, in the case of a new or a rare Rose, we obtain ten plants on the Manetti to one by cuttings; the stock also imparts a vigour to weaker sorts which they would never have on their own roots. In short, I think that one of the greatest advantages of the Manetti stock is that it supplies strength to the Rose, so as to enable it to make a perfect plant on its own roots, and thereby to give it a permanency, in which the old Dog Rose signally failed. I do not mean to say that there may not be many very fine old trees found on the Dog Rose, but there are two drawbacks to it—one is that in its wild state the Dog Rose is constantly renewing itself by root suckers; every year the suckers that are sent up are stronger and stronger, and the old wood dies back. Any person may see this for himself, if he will examine an old hedge where the Dog Rose has been allowed to run wild, without being cut for many years. He will find it full of dead and dying old wood, while the tree is spreading itself with suckers. Now, by budding Roses as standards on the Dog Rose we are budding on a stem which would naturally die in thirteen or fourteen years, and is constantly seeking to renew its life by pushing out suckers, which are the constant plague of all rosarians who adhere to the old-fashioned standards. We are, consequently, fighting against Nature, and only keep up the life of the stem of the standard by cutting off the root suckers, and encouraging the growth of the head. The second drawback to the old Dog Rose is that all the head of the Rose budded on it is above ground, and is, therefore, subject to frosts. In the winter of 1860 I lost every standard that I had but two, and not a single plant on the Manetti stock. This was the case all over the north of England. Mr. May, of Bedale, did not, I believe, save one standard in every thousand out of an extensive stock of Roses.

One word about soils. The best soil for Roses on the Manetti stock is a good, rich, garden loam, not too sandy or too yellow; it is not suitable for a clay soil unless the beds are specially prepared with plenty of leaf soil and manure, and well mulched both winter and summer with short manure or cocoa-nut refuse. Wherever, then, the soil is a tenacious clay it is better to adhere to the Dog Rose; and after all there is no soil that gives so much colour to Roses as marly clay. Where do we see finer colour than in the Roses shown by the Rev. S. B. Hole? Manetti will also do in light and sandy soils, where the Dog Rose entirely fails; but in these soils it is better to plant deeper, and to encourage the growth of roots from the Rose itself.

In concluding these remarks, I digress to "P.'s" letter, and agree with him, that the blooms of King's Acro, shown by Mr. Cranston at the Crystal Palace, were certainly not up to the mark; but we must remember they were cut in exceedingly hot, dry weather, and had travelled all the way from Herefordshire.—C. P. CLEAVER.

THE MANGOSTEEN.

HAVING noticed in your last Number a letter from Mr. Smith, ex-curator at Kew, touching the mode of propagating the Mangosteen, allow me to say a few words in reply. In the first place, then, I think I ought to be a fair judge of what is and what is not the true Mangosteen, having received many trees myself from Karang and Singapore, which were selected with the greatest care by an experienced person there. A friend, too, in India, who is a first-rate botanist, has frequently sent me seeds of many varieties of Mangosteen and Platonia.

In the second place, while quite agreeing with Mr. Smith that raising the Mangosteen from seed is by far the preferable way, I feel certain that any variety may, with care, be raised from cuttings, and that the cuttings will strike in from six to eight months. Several of our largest nurserymen have, and are now, raising them in this manner. Paxton, too, in his "Magazine of Botany," speaks of Mangosteen cuttings rooting in sand under a hand-glass, and I have reason to know that he successfully raised plants in that way himself. True plants of

this fruit are not quite so rare, either, as Mr. Smith supposes, and I could name many places where the true Mangosteen tree may be seen growing.

Mr. Smith's suggestions about the carriage of the fruit and seed are most valuable, and will doubtless be acted upon by many persons, myself among the number. It is so infinitely superior a way of obtaining them to the modes now in general use, such as packing in soil, coating with wax, collodion, &c., that he deserves the thanks of every tropical plant grower.—J. H.

THE COILING OF VINES IN POTS.

I THINK I remember telling your readers that I should this season try the effect of coiling some Vines in pots. I therefore early in January last operated upon a dozen Vines, by coiling the lower part of each rod, just within the rim of the pot, so that each coil was covered from 1 to 2 inches in depth. The pots were then placed on a hot-water pipe in their usual place in my Orange-house. They seemed at first not to break so quickly as usual, but they are now growing very vigorously and showing very fine bunches.

A few days ago I was induced to examine the coils to see if they were rooting as freely as my old friend predicted they would. I found roots protruding from every portion of the coils, but more profusely from those nearest to the surface. They, in fact, have put forth more roots from those parts barely covered—i. e., covered with a quarter of an inch of earth, than from those covered 2 inches in depth. I observed, also, that the portion of coil very near the surface put forth roots earlier by a fortnight than that more deeply covered. I have thus advanced a step, and if I am spared I shall in future cover the coil with only half an inch of compost. The young fresh roots spreading themselves over the surface look so plump and healthy, with their delicate pink and white tints, that I cannot help looking at them with interest, and I cannot but think that they must give much additional vigour to the Vines. To help on this I shall very shortly give them some fresh surface food with my usual surface-dressing compost—malt dust and horse-droppings saturated with liquid manure.

Allow me to correct myself. On reading to-day (April 6th), my article which you inserted at page 237, I find that I have made an incorrect assertion, which I should have corrected if I had seen a proof. At the foot of the seventh paragraph the sentence should read, "Many of the two thousand pyramids on the Quince," instead of "The two thousand." The truth is, the plantation was commenced upwards of twenty years ago, and took some years to complete. I am this season adding to it six hundred trees, 3 feet apart. Last year I did the same, so that the aggregate will be much above two thousand trees growing in ground less than one acre in extent.—T. R.

WATER, AND THE CONSEQUENCES OF ITS IMPURITIES.

I wish some chemist would study the subject of water as it affects the plants to which it is applied in an artificial manner; for I am confident that it has more influence on their well-being than the character of the soil in which they are planted. In affirming this much, I mean the assertion to apply to that class of plants kept in pots, and of which the existence is maintained from day to day by what may be termed regular meals of water; and as the number of such is very great, it may be inferred that the class of food most relished by them is not always that which is given to them: hence disease is the consequence, or, if the evil do not advance thus far, lack of vigour or health.

Plants are created to live in fixed stations, and at such stations they are furnished with all the requirements necessary for their well-doing. The chalky hills are clothed with Yews, Junipers, and Box, and amongst the herbage we find Wild Thyme and numerous British Orchises, while such water as is to be obtained there is much impregnated with the calcareous constituents of the substratum. On the other hand, soils of a peaty character have the Scotch Fir and Birch, with an undergrowth of Heath and Whortleberry, with Ferns in greater or less variety, and the water obtained from them is widely different from that found in the other locality. It contains iron and vegetable extract. Such water is just the kind that is wanted to secure the well-being of the plants there, and they thrive with it, and the harmony which Nature presents us

with in all her works is here as well as in the former case fully borne out.

The above cases represent what water is after having been in contact with the various substances that constitute the surface, or, it may be, the substratum. The one is impregnated with substances hostile to the plants growing in the other soil. Taking the practical view of the subject, it is only necessary to step into the first garden of note where there may happen to be as many as one hundred different kinds of plants in pots, and on inquiry most likely we shall find that these plants are from districts differing widely from each other in their geological formation. The sandy plain, limestone ridge, the morass charged with ferruginous matter, and the lofty peaks of granite, have all been explored to find these plants, and, until lately, instructors in the art of plant-growing contented themselves with merely describing the soil they were to be planted in, not giving the subject of water the least attention, or rather not saying a word about the quality of that water, beyond pointing out how much water such a plant ought to have, and making similar remarks. This advice, no doubt, is good enough, when pure rain water can be had, but water is so very seldom found in that condition, that evils must arise to some of the plants to which it is applied; and, no doubt, one of the causes of particular classes of plants not doing well at certain places, is the water with which they are fed not suiting them. Taking, for instance, the case of a potted plant which receives water almost every day, it need not be surprising that where such water is of an exactly contrary kind to the soil which the plant delights in, such a mixture cannot be otherwise than injurious.

Let us take, for instance, a very common case, and one that may often be met with. A collection of Cape Heaths is formed by some skilful and attentive cultivator at a place where we may say that chalk or lime forms the substratum, and, consequently, is a component of the soil of the district. Peat, however, of excellent quality is imported from a distance, and for a time things go on well. Rain water is collected and supplied to the plants; but dry weather sets in, and the rain-water butts fail, and recourse must be had to the well at a time when the plants require more water, and all classes of plants are perforce supplied with spring water. The effects of this are not apparent at first, but a continuance tells, and some of the more delicate of the Heaths show unmistakable signs of declining health, if not absolute disease, when, perhaps, their downward career is arrested by a copious rain refilling the water-butts, and the plants are again put on more befitting food. Another dry period may, however, succeed, and the conclusion may be arrived at, that as the Heaths do not seem to thrive, there must be something wrong.

Such cases are numerous, and call for some mode of removing from water those substances which it has acquired in its contact with the earth, and restoring it to the condition in which it fell from the clouds, and that is unquestionably the best possible form in which it can be supplied to plants.

Can our chemical friends effect this by any simple, cheap, and efficacious means? Assuredly something can be done, and it is well worth the consideration of that class of experimentalists whose aim is to improve the many necessaries of the public, and this is one not merely beneficial to the vegetable world, but to animal life also.

Water cannot even remain long in contact with the vessels or substances contrived to hold it without imbibing some foreign matter from such receptacles. The difficulty of preserving rain water pure and fresh for a lengthened period is greater than may be expected. Tanks sunk under the surface are often used; but if the ground be porous, such tanks have to be lined with something that will render them water-tight. Lead is thought too expensive in many cases, and accordingly cement is used, and Portland cement, which has the reputation of being the best, certainly imparts an extreme hardness to the water at first, rendering it worse than even ordinary well water. This tendency to cause hardness goes off by degrees; but it is often years before it entirely disappears. Water from tanks having such an effect, I need hardly say, is very hurtful to plants, and it should, therefore, if possible, be avoided. Remedies of the ordinary practical sort have not yet become sufficiently known or brought into use. Some years ago it was said that a charcoal fire made in the tank before it was used would counteract the tendency to produce hardness; but practice soon discovered that such a mode was destructive to the tank, and it has only been partially adopted. With time and patience a tank will become seasoned; but three or four years are often required to do so, and this cannot always be allowed.

Much more might be added on this head, but enough has been said to prove the importance of the question; and as the surface of the earth on an average receives in the eastern parts of the kingdom about 24 inches of water in the form of rain every year, it is not too much to say that the quantity given by hand to plants in pots amounts to at least ten times that quantity, and must, as it assuredly does, convey to the plant much of its daily food. It is not assuming too much to say that far better results would follow if such food were of the same kind as supplied by Nature.—J. ROBSON.

SOWING AND AFTER-MANAGEMENT

OF FÆLARGONIUMS, VERBENAS, AND OTHER CHOICE SEEDS

(Continued from page 85.)

THE VERBENA.—It is often difficult to induce the seeds of the Verbena to vegetate; great caution is, therefore, necessary in keeping the soil as nearly of an equable temperature as possible after the seeds have been sown. Care must also be taken to keep the soil in the same state of moisture till after the seedlings appear above the surface, when they should be immediately pricked out into small pots or pans. If either of the above conditions be allowed to vary, the vegetation of the seeds may be prolonged to an indefinite period, and then it often happens that the seedsman falls into disrepute, although the fault is not in the seeds but in the management of them after they have been sown. Sometimes under favourable conditions Verbena seed will vegetate in five or seven weeks, and I have known it remain in the soil for more than two years before it germinated. Some of my very best flowers have been obtained from seed that has remained dormant in the soil for upwards of two years. This fact should teach us the necessity of exercising our patience when we have sown a pan of choice seeds, and, if the seedlings do not appear at the proper time, not to throw the contents of the pan to the rubbish-heap.

If the seedlings do not appear in seven or fifteen weeks, my plan is to carefully turn out the soil in which the seeds have been sown, have some fresh pans crocked, and then place the soil in these, mixing with it a little fresh soil, and finishing off with half an inch of fresh soil on the surface. I then water the pans through a fine rose, and place them again in a similar temperature to that in which they previously were. I have often found Verbena seeds vegetate very freely after having been thus treated. If, notwithstanding, I do not obtain the number of plants which I consider I ought from the quantity of seed sown, and if the seed is particularly choice, I give it a third chance. I first select a corner that is not likely to be wanted for fifteen or eighteen months. Here an old box is placed on a very gentle hotbed, some good soil is spread over the bed, the contents of the pans are turned out and levelled all over the surface, and an inch or two of good soil having been placed on the top, a good watering is given. I have often on looking over the box on the fifth or sixth day afterwards, noticed lots of the little lance-shaped leaves appearing above the soil, then with a small saucer or a leaf in one hand and a piece of wood, in shape something like a table-knife, in the other, I quickly remove them, but in doing this the piece of wood must be pushed down below the root of the plant, which should then be lifted gradually up so that it may be loosened from the soil without breaking it, for if this is not done very carefully it will be sure to snap off midway between the root and leaf. When this happens in most cases all the skill that can be brought to bear will prove of no avail; but if the plants, however small they may be, are taken up without injury to their roots, they will grow if proper care be taken in pricking them into fresh pots, or pans, of good soil and in attending to them afterwards.

I prefer pricking-out the plants round the side of the pot, and as close to it as possible. They should also be pricked into the fresh soil to just the same depth as they were at before taking them out of the seed-pan or box. If they are placed in a temperature of 75°, they will soon grow very freely, and as soon as they have made three or four pairs of leaves, they should be again pricked out into boxes, or potted singly into large 60 or 48-sized pots.

As soon as the plants have become partly established in the pots or boxes, if the seed is from very choice varieties, I take off the top of each plant and strike it. This will be very soon in flower, and the parent plant in the meantime will become stocky. By the time the latter is ready for planting out the cutting will have flowered, proving whether it is worth while to

grow on the parent plant or not. In any case, whether the top be struck or not, it should be pinched out at the time stated, in order to cause the plant to furnish itself nicely at the base. If this precaution is not taken there is some difficulty in judging of the habit of the plant the first season.

In planting the seedlings out choose a nice open piece of ground, and plant them in rows about 3 feet apart, and at 2 feet apart in the rows. As soon as the plants have taken hold of the soil all the points should be again pinched out; this will increase the number of shoots more than tenfold, and about the second week in July the plants will produce a magnificent display of bloom. When the cutting is taken off a label should be put to each plant and cutting so that no mistake may take place, and if the colours are noted down as the flowers are produced, the plants may be so placed that when in bloom their colours may harmonise in the beds, and prove more effective than would otherwise be the case; or if the seedlings are planted out on a border indiscriminately, nothing produces a more pleasing effect to the eye than the varied colours of several hundreds of seedling Verbenas in mass.

I find old seed always vegetates quicker than new; for this reason I always keep a year's seed in hand. If the seed is sown in pans or pots these should be prepared as recommended for Pelargoniums. The same sort of soil will suit the Verbena and Pelargonium, but the seed of the Verbena must be sown quite 2 inches deep.

The plants must be well watered after they are planted out. If there is a slug or a snail anywhere it is sure to find out a seedling Verbena, and the only sure way to get rid of these troublesome marauders, is to catch and kill them. The best time to do this is about 11 p.m. I then generally find them very busy enjoying their supper at my expense; and although they are not very pleasant to handle, I find the only way you can be sure of destroying them is to pick them up and drop them into a vessel containing a little hot water or lime.

I hope to produce some varieties this season that will please even "D." of Deal, who has given us his ideas on the merits and demerits of the best Verbenas sent out up to the present time. "D. Deal," is quite right in stating that of the new varieties sent out every year many do not come up to the required standard, either for bedding-purposes or for pot-culture; but he is not right in stating Purple King to be the best bedding Verbena out. Many of the varieties sent out by Messrs. E. G. Henderson during the last five or six years are equal to Purple King in point of habit and profusion of bloom. The reason more of the Verbenas sent out do not possess the desirable habit of Purple King is, that the latter is the most shy of all Verbenas in producing seed. Last summer, however, its character was very much altered, and we may hope to see another year varieties of other colours with the habit of Purple King.—J. WILLS.

(To be continued.)

PRIZES FOR ALLOTMENT GARDENING.

I INTEND offering at the next exhibition of our local floral and horticultural society prizes for the best and second best cultivated allotment gardens, but being doubtful what the points of excellence should be, I venture to ask you for advice.

I propose that the gardens shall contain an area of not less than 200 and not more than 400 yards; that they shall have belonged to the exhibitors for at least six months previous to the show, and have been cultivated by the owners themselves, or, at all events, without paid labour.

Flowers and vegetables, of course, must be grown, and the smaller fruits also; but in this cold climate (close to the sea, on the north-east coast), other fruits, except probably Apples and Pears, are out of the question. Order and neatness must form essential points of excellence.

Will you give me your advice as to the conditions I should make?—S. I. R.

[We think the terms you propose for prizes for gardens are very good. In awarding prizes for such gardens good culture should form the first feature, bulk of cropping from the land a second feature, and neatness and good keeping the third feature. It will tend to give more satisfaction to all concerned if the number of kinds of vegetables for competition be stated—say twelve varieties; and the kinds of fruit should also be specified, or there will be heartburnings. As the result of some experience, if we gave prizes for the best cultivated and the neatest-kept allotments, we should have them judged on general prin-

ciples, independently of varieties of vegetables and fruits; but even then the satisfaction would not be so general as would follow the giving prizes for the best collection—say ten or twelve kinds of vegetables, best of fruit—say six kinds, and best of flowers. It should always be kept in mind in judging cottagers' productions that bulk of good eatable matter should be a primary consideration. A Cauliflower for a gentleman's table will be most esteemed when small and compact; for a cottager it will be best if firmish and close, though as large as a little parsel.]

VISITS TO GARDENS PUBLIC AND PRIVATE.

PRESTON HALL, AYLESFORD, NEAR MAIDSTONE.

THE SEAT OF EDWARD L. BETTS, ESQ.

THERE does not seem much advantage to be gained by visiting a garden in the month of April, in the midst of a downpour of rain such as even in this "pluvius" season one has seldom seen equalled; and probably the vision of a respectable and more than middle-aged parson trudging through it, with umbrella overhead, and dodging in and out of houses, and peering into this or that frame and pit, was more suggestive of mental hallucination than of anything else. A long-made and often-deferred promise, however, induced me to make the attempt; and business having brought me to Maidstone, which is only a few minutes by rail from Aylesford, I made the attempt, and did it; but I thought as my little daughter and I trudged up to the Hall, Well, I dare say we shall be taken for some respectable kind of tramps, who whose such a day because they thought no one would be hard-hearted enough to refuse them. I need not say how we were looked at—we certainly were not turned away. Of this, however, I am certain, that if a garden at such a time is worth looking at, if all is in order, and neatness prevail, then you may be quite sure that things are done well, and that if you can drop in at a more convenient season you will infallibly find much that is worth noting; and such was the case here. Mr. Bradley is evidently up to the mark, and all I saw showed that he understood what was wanted, and had it done. He knew exactly what his employers wanted, and set himself to meet their wishes; and this is what I conceive is a gardener's work—not to have whims and crotchets of his own, but to study his employers, and, if they choose even to have whims and crotchets, to humour them.

Preston Hall was the seat of the old Kentish family of Milner, and came into possession of Mr. Betts upwards of twenty years ago. The present mansion is entirely new, and is a very handsome edifice, built of the finest Kentish rag, and in the palatial or Italian style. Its rooms are beautifully proportioned, and all that wealth and taste can supply are to be found in the reception-rooms, which contain, *par excellence*, some *chefs d'œuvre* of our first modern artists. In the dining-room, a handsome oak room beautifully carved, are some marvellously fine paintings; on panels on either side is the second scene from "As You Like It" by Maclise, full of his marvellous drawing, and with less of his defects than in any of his works. The contrast between the brawny Charles, the wrestler, and the stern and supple Orlando is admirable; while Rosalind suggests the idea that he could not fail to win when her smiles favoured him. An exquisite Clarkson Stansfield, representing the port of La Rochelle, "fair city of the waters," hangs next to it—a masterpiece indeed; while on the other panel is a beautiful Cope, representing the patient Griselda claimed as the Prince's bride. On the other side of the room is a fine landscape by Creswick, "Clearing up after a Shower," which many will recollect in the Academy, the figures by Bottomley; and on the other side of the fireplace is a wonderful sketch by Maclise. The space was not filled up; and so one day, with a piece of charcoal and a bit of chalk out of the billiard-room, he drew a masterly group, which Mr. Betts with rare good taste has allowed to remain, and has had it glazed over; but perhaps the gem of the room, though hung too high up, is the magnificent painting of Sir Edwin Landseer, familiar to many from the engraving, of "The Hills above Braemar;" a magnificent stag, with some hinds, and the highland hare, displaying all the artist's masterly handling. Here are also fine portraits of Mr. and Mrs. Betts, Sir Morton Peto (Mrs. Betts's brother), and Mr. Betts's father. But here am I writing about paintings instead of gardens. Let my excuse be, that it was raining so tremendously that we were fain to keep under shelter for a while; and so my little gessip is pardonable, I hope.

Opening from the dining-room there is a very handsome conservatory surmounted by a dome, which at the time of my visit was filled with fine specimens of Azaleas in full bloom; while in the passage up to it were arranged flowering plants, Hyacinths, Lachenalias, Tulips, &c., in pots. Nothing can be more satisfactory than a conservatory like this, affording as it does a treat at all times to the lover of floral beauty—in weather when, perhaps, a person would be very unwilling to trudge down to the garden. The house is situated on a terrace, and in front is a well-arranged geometric garden, which, doubtless, further on in the season will be resplendent in those varied hues of the rainbow which the modern system is so well calculated to supply. The walk from the mansion to the garden is lined on each side with some fine pillar Roses, backed with specimens of various conifers, among which were two of the best feathered Araucarias that I have seen.

The range of hothouses and greenhouses, frames and pits, is very extensive, and they were all well at work. In the Muscat-house were some very promising bunches of the Muscat of Alexandria, looking as if they would sustain the fame that Preston Hall has acquired for its Grapes. At the other extremity of the range was another house, the Vines in which had suffered from the extreme heat of the autumn of last year. They had been pruned back in August in order to get an early start for this season; but the hot September had started many of the eyes, and hence the crop was irregular. Peaches and Nectarines were forward, as large as hens' eggs, and the trees evidently in healthy condition. In the plant-houses there was an excellent assortment of plants with fine foliage, &c., suitable for the decoration of the conservatory, &c.; while in the pits were appliances for forcing flowers of all kinds, and Camellias and Azaleas, which had already yielded their sweets, were being started into fresh growth for another season. Strawberries also were bloomed in these pits, and then brought into the houses to be placed on shelves to be fruited, Mr. Bradley preferring this plan. The Cucumber-pits were filled with an excellent crop of Lord Kenyon's Favourite, this, I believe, being generally considered the best kind for winter purposes. The fruit is not long, has no spines, but is straight and well-formed. Personally I do not think it in flavour or crispness equal to some others, although it is used here all through the year. All Mr. Bradley's plants are grown from seed, not cuttings, so that each process seems to answer when properly managed.

Leaving this portion of the garden you pass down a long shrubbery, in the centre of which is a handsome aviary, to the kitchen garden, where there is a long range of glazed walls, which, however, I find are not much in favour here; and after all, if you want to obtain flavour, richness, and size, there is, despite all that has been said to the contrary, nothing like the regular Peach and Nectarine house; and to my mind one good fruit is worth half a dozen of inferior merit. Everything in this garden seemed to be in admirable order, and I only regretted that weather and season were so against my seeing it. However, I promised Mr. Bradley I would pay him a visit again at a more propitious season; and I have no doubt that if any of the readers of "our Journal" (for we had a little chat about it, too), are in that neighbourhood, they would be cordially received. I believe that the house may also be seen on the presentation of a visiting card; and if the visitor has even a *souçon* of a taste for art, I warrant that he will not consider the time thrown away.—D., Deal.

VINES FRUITED IN ALTERNATE YEARS.

I HAVE grown Grapes in a late vinery for many years on the plan suggested by your "CONSTANT READER," page 255—viz., the Vines are planted 2 feet apart, and fruited alternate years. The Vines which bore fruit last autumn were cut down to the ground about Christmas, and are now making new rods for fruiting in 1867.

The plan answers well. I had upwards of five hundred bunches last year, many large, out of a house 30 feet long by 12 feet wide. These rods of last year's growth are now showing two and three bunches of fruit from each eye. The sorts are Black Hamburgh and Muscadine, or Sweetwater.—ROBERT WARNER, Broomfield.

SIZE OF PEACHES.—In your Number of the 3rd inst. I see Mr. Snow, of Saltram Gardens, speaks of having seen Peaches that were grown in an orchard-house measuring 9½ inches

round. It may be interesting to know that I had some fruit on trees in my orchard-houses last season that measured 11½ inches in circumference.—RICHARD SMITH, Nurseryman, Worcester.

TOBACCO CULTURE IN ENGLAND.

UNDER the title "Growing Tobacco," page 263, in answer to a correspondent, "J. H. M. R.," there appears the following reply—"It is not illegal to grow Tobacco for your own use." Now, it seems to me that this statement is too broad and ought to be qualified, and my reason for saying so will appear more plainly if the Acts which prohibit the planting, setting, or sowing of Tobacco in England, Scotland, or Ireland are referred to. 1 & 2 William IV. c. 13 (1831), seems to be the last Act on the subject, and at the end of section 1 of that Act the following passage occurs:—"And that it shall not be lawful to plant, set, improve to grow, or cure either in seed, plant, or otherwise, any Tobacco in any part of the United Kingdom, save and except in the places and in the quantities and for the purposes in the said Acts mentioned and allowed."

The first Act, referred to in the Act of 1831, is 12 Charles II. c. 34 (1660), which was passed for prohibiting the planting, setting, or sowing of Tobacco in England or Ireland. Section 4 of that Act contains a saving clause—"Provided always, and it is hereby enacted, that this Act nor any thing therein contained shall extend to the hindering of the planting of Tobacco in any physic garden of either University, or in any other private garden for physic or chirurgery only, so as the quantities so planted exceed not one-half of a pole in any one place or garden." This Act, therefore, last quoted confines the growth of Tobacco to certain limits, to certain places, and for certain purposes in England or Ireland.

The same saving clause occurs in 15 Charles II. c. 7 (1663), also referred to in the Act of 1831. So much, however, of the two Acts of 12 & 15 Charles II., which prohibited the planting of Tobacco in Ireland, was repealed by 19 George III. c. 35 (1779).

The Act of 1831 was passed to repeal the Act of 1779, and contains in section 1 the following passage:—"And whereas it is expedient to repeal the said recited Act of the nineteenth year of the reign of his said Majesty King George the Third, and to revive in and extend to Ireland the said recited Act of the twelfth year of King Charles the Second, and of any other Acts since passed for prohibiting the growth and culture of Tobacco, be it enacted," &c.; and at the end of the section appears the passage above quoted, ending with "mentioned and allowed."

Another Act, containing in the 13th section the same saving clause, was passed in 1670 (22 & 23 Charles II. c. 26), to continue in force for nine years. This Act was continued by 5 George I. c. 11, sec. 19, so long as 12 Charles II. c. 4 (1660), should continue; and by 22 George III. c. 73 (1782), the Acts prohibiting the culture of Tobacco in England were extended to Scotland.

Now, there is no doubt in my mind but that the question of "J. H. M. R." was suggested when reading the article on "The Growth and Manufacture of Tobacco for Fumigating-purposes," which appeared in your Journal (page 137). On seeing that paper I myself was surprised that no mention was made as to the quantity allowed by English law to be grown on English soil or elsewhere, and my curiosity was aroused into a search for the "Tobacco Acts," when the reply appeared to "J. H. M. R.'s" question at page 263. In Tobacco culture it is best to be careful; for section 4 of the Act of 1831 provided (subject to the above-mentioned saving clauses), "That if any Tobacco the growth of any part of the United Kingdom, manufactured or unmanufactured, or mixed with any Tobacco of foreign growth, shall be delivered to, received by, or found in the possession of any manufacturer, dealer in, or retailer of tobacco or snuff in any quantity whatsoever, or if any such tobacco shall be delivered to, or received by, or be found in the possession of any other person or persons whatsoever in any quantity exceeding 1 lb. in weight, . . . the person offending in any of the cases shall forfeit the sum of £100." Is there not then some limit to the growth of Tobacco for private use? Can any of your readers throw any light upon the subject?—X., Surrey.

[You are quite correct in observing that our answer was too broad. We intended to reply that any one might grow a few plants of Tobacco for his own use for gardening purposes. Even this may not be strictly legal, but would not be visited

by any penalty. It is quite certain that no one must grow Tobacco in England either for smoking, or to sell for any purpose.—Eos.]

ROYAL HORTICULTURAL SOCIETY.

SECOND SPRING SHOW—APRIL 12TH.

ON this occasion there was a brilliant and effective display in the conservatory arcades, the principal feature being gorgeous masses of Azaleas from Mr. Turner and Messrs. Lane. Those from the former, especially, were perfection as regards blooming, and the pyramidal training, it may be remarked, was not so close and stiff as in past years. Messrs. Lane's specimens, though not so large as Mr. Turner's, were also wonderfully fine, notwithstanding the comparatively small pots in which they were grown.

In the class for nine Mr. Turner was first with Louise Von Baden, Queen Victoria, Belle Gantoise, Perryana, Union, being Etoile de Gand and Variegata superba on the same plant, Roi Leopold, Due de Nassau, Magnificans, and Enlilie Van Geert. Messrs. Lane were second with Bolfordi, Souvenir du Prince Albert, Rosa alba, Advance, Souvenir de l'Exposition, President, Secn taire Claus, a beautiful variety, Perryana, and Enlilie Van Geert. Most of the above had already appeared at the Regent's Park on the previous Saturday, and were noticed in the report of that Show. For six Mr. Turner was again first with Flower of the Day, white, flaked with red; Prince Jerome, Brilliant, Magnifica flore pleno, rosy purple, and Magnet, with large rose-coloured flowers. Messrs. Lane were second with Cheloni, Violaena superba, a very showy rosy purple; Magnificent, Putimadora, Conspecta purpurca, and Enlilie Van Geert. For a single specimen Mr. Turner was first with Criterion, a handsome pyramidal plant, about 5 feet high, and densely covered with bloom; Messrs. Lane second with Reine des Blanches, a fine large-flowered white variety; and Mr. Young, gardener to R. Barclay, Esq., Highbate, third with a large plant of India alba, but not sufficiently in bloom. In the Amateurs' Classes some plants in good bloom were shown by Mr. Todman, gardener to R. Hudson, Esq., Clapham, and Mr. Young, the former receiving first prizes for six and three plants, and the latter a second prize for three. Among the best were Roi Leopold, Concium, purplish, with lilac crimson spots; Semi-duplex maculata; The Bride, white; and Coronata. Messrs. Lane likewise exhibited a collection of twenty-eight plants, which were very even in size, and in excellent bloom. Madame Ambroise Verschaffelt, Reine des Blanches, and several others of the varieties were noticed last week. Two new varieties, called George Eyles and Fire King, were exhibited by Mr. Turner. The blooms were about 3½ inches in diameter, orange scarlet, in the latter conspicuously spotted with dark crimson in the upper petals, in the former more lightly spotted.

Cinerarias, it must be confessed, did not constitute an effective portion of the display, although several of the plants were in good bloom. They came from Mr. Fairbairn, gardener to the Duke of Northumberland, Sion; Mr. Clarke, Whittin; Mr. James, gardener to W. F. Watson, Esq., Isleworth; and Mrs. Hooke, Fulham, to each of whom prizes were awarded. Among the varieties exhibited were Captain Schreier, blue; Bob, Lord Ilgin, Favourite, and Aimee, shades of rosy purple; Charles Dickens, Anne, Bertie, and Densa, broadly edged with the same colour, the last of compact growth, with the flowers close above the foliage. Of Calceolarias, half a dozen plants in good bloom were shown by Mr. James, and a like number of Amaryllids by Mr. Young, who also contributed a tray of Camellia blooms. Cyclamens in charming bloom came from Messrs. E. G. Henderson, Mr. Wiggins, Mr. Fairbairn, and Mrs. Hooke; and fine pots of Lily of the Valley from Mr. William Paul.

Leaving the Roses, which alone constituted a beautiful display, and the Auriculas, and their kindred flower the Polyanthus, in the able hands of "D. Deal," we now come to the miscellaneous subjects.

Among these was a collection of Rhododendrons from Messrs. Lane, ranging from 18 inches to 2 feet in height, and in profuse bloom. From Mr. Fairbairn, Sion, came an excellent collection of flowering and fine-foliaged plants, consisting of Camellias and Eriostemon nerifolium in excellent bloom; Phajus Wallichii, Foxbrnsh Acrids, Phalenopsis grandiflora, two fine plants of Lantana horibonica, Pothos aculalis, with shining green leaves from 18 inches to 3 feet long, and 9 or 10 inches broad; narrow-leaved Croton, Caladiums, Asplenium bulbiferum, and half a dozen pots of the pretty Selaginella apoda. Messrs. Lee likewise contributed a very effective group, comprising six standard Azaleas, several fine Camellias, standard Fuchsias, Hedera fuchsoides, Heaths, Tremandra cricifolia hirsuta, a pretty, compact, lilac-flowered plant; Cyrtobidm maculatum with five good spikes of bloom, Dendrobiums and other Orchids, and fruiting Aucubas. Mr. Bartlett, Hammer-smith, contributed four groups, one of which consisted of Roses, Cinerarias, Polyanthus, &c.; another of Dielytra spectabilis, Tulips, and Hyacinths; a third of Hyacinths; and a fourth of Narcissus surrounded with a row of Hyacinths. These groups were very tastefully arranged on four tables in the front of one of the arcades, and edged with Isoplepis gracilis. An effective group was likewise furnished by Messrs. F. & A. Smith, of Dulwich, and consisted of several Acacias in excellent bloom, Eriostemons, Azaleas, Heaths, Aphelaxis, Cinerarias, Draenas in bloom, and a few Orchids. Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, and Mr.

Young also exhibited mixed groups, comprising Pelargoniums, Rhododendrons, Azaleas, Epacris, Cytus, Draenas, Tulips, &c. Mr. Reeves, Ladbroke Nursery, Notting Hill, whose admirably bloomed specimens of Dentia gracilis have been noticed in previous reports, again produced plants of a similar character; Messrs. Paul & Son again exhibited cut Roses, and Messrs. F. & A. Smith new Zonale Graniums and Cinerarias, including Perfection, described last week. From T. Lascombe, Esq., Combe Royal, Kingsbridge, came blooms of Rhododendron arboreum and of Sikkim species and hybrids; also of Camellias, all of which had been grown in the open air in the mild climate of that part of Devonshire; likewise a basket of Oranges, Lemons, and Citrons, and fruit of other members of the Citron tribe, produced there without the aid of glass or artificial heat, and with only the protection of reed frames. Several of the fruit were very fine.

Of new and rare plants, Mr. Bull again brought forward a numerous collection, comprising Arumaria Rubra, Maranta splendida, with beautifully marked dark-green foliage; Psychotria macrocephala, with fine heads of white flowers; Aspidistra Sieboldi, Imantophyllum minimum, of which Mr. Bull possesses an excellent variety; the beautiful Sonerila margaritacea, Bignonia argyrea violaceus, Draena Cooperi, Cyrtopodium villosum, Trichopogon suavis, &c. Messrs. E. G. Henderson sent Genista prostrata, a plant of pendulous habit with showy bright yellow flowers; a promising variety of Ceanothus Dampieri, in which the standard is scarlet, but the head whitish, tipped with scarlet; and Hedera japonica argentea, a small-leaved Ivy, distinctly variegated with white. From Mr. Turner came a variety of the well-known Kerria japonica, or Corebous, with single flowers and the leaves variegated with white, and which, if equally ornamental when in an older state, will be a useful addition to hardy variegated plants. Kæmpferia ovalifolia, a plant which, though not new, is rarely seen, was exhibited by Mr. J. Murdell, gardener to J. C. Pickersgill, Esq., Coulsdon, Surrey. Its white and purplish lilac flowers are produced before the foliage, and though only enduring for a day or two, are thrown up in succession from the Caladium-like roots for a period of about five weeks.

As on the last Show, Mrs. Mitchell, Anglesa Terrace, Battersea, exhibited various flowers modelled in wax, as Lilliums, Magnolias, Roses, Pelargoniums, and Mignonette. Though not forming a part of the Exhibition, we may add that one of Beard's patent glass houses, a span-roof, upwards of 30 feet in length, has just been put up, so that those who may be desirous of seeing this new system of construction, will have an opportunity of judging for themselves. The house, although not yet stocked with plants—in fact, barely completed, has a light and elegant appearance.

A list of the awards will be found in our advertising columns.

The display of Roses in pots was exceedingly good, and much interest was attached especially to the class of new Roses in pots, inasmuch as it was distinctly stated for those of 1865 and 1866. At the same time it must be borne in mind that in this state we do not see them always in their true character. There were, for example, two plants of John Keynes; in one collection it was rough, ragged, and unpleasant-looking; in the other it was a beautifully shaped flower. Again: Roses which are somewhat difficult to open do not display their beauties so well in this method and time of showing. Souvenir de la Malmaison, for example, was by no means what it would be some time later; and often in colour we should fail to recognise many of our older friends at this time of the year. I now give the Roses as they struck me, and must again premise that I only speak of them as they were there, not as to their general merits, except where so distinctly stated.

Mr. Wm. Paul took the first place with a very beautiful collection, comprising General d'Hautpout; Jean Rosenkrantz; Josephine Beanharnais, like Louise Peyronny; *Glory of Waltham, a large fine-coloured flower—"d'un grand effect," as our neighbours say; *Mademoiselle Marguerite Dombrain, exhibiting a difficulty of opening, it appeared to me; Madame A. Verschaffelt; *Dr. Lindley, fine; Madame Moreau, excellent; Achille Gonod, coarse; Charles Margottin, showy crimson; Prince Eugene Beanharnais; John Keynes, rough; Triomphe des Français, well-shaped, rose; Marcelle Niel, fine; Mademoiselle Amelie Halphen, fine and full; Marcella, light pink; and Souvenir de Bernardin St. Pierre. Messrs. Paul & Son were second, and exhibited Xavier Olibo, fine rich crimson, good petal and shape; *Pine, promising flower; General d'Hautpout; Madame Moreau; Dr. Andry, fine crimson; Duchesse de Caylus, fine; Duchesse de Medina Celi, poor; Elizabeth Vigeron, rough; Duke of Wellington, splendid rich colour, fine flower; Madame Roussel, bright lively pink; Souvenir de Wm. Wood, very dark; Marguerite de St. Arnaud, rough; Rushton Radelyffe, fall; Belle Rose, rough; and Souvenir de Bernardin St. Pierre. Mr. Charles Turner, of Slough, had John Keynes, very beautiful; Madame Hermann Stenger, rough; Madame Moreau, fine; Madame Fillon, rough; Madame Engene Appert; *Mademoiselle Marguerite Dombrain, very full, like her mamma La Reine, and having, I fear, her defect; President Mas; Abraham Lincoln; Madame de Pontbriand, not open; King's Acre, inclining to be coarse; Dr. Andry, very brilliant; Josephine Beanharnais. I have marked with an asterisk the very new ones.

In the class of nine Roses in pots, Mr. Charles Turner was first with some beautiful plants of Madame William, Jules Margottin, Souvenir de la Malmaison (not quite open, and rough), Souvenir d'un

Ami, Gloire de Dijon, Général Jacqueminot, Victor Verdier, Le Rhone, Alba rosea (very beautiful). Messrs. Paul & Son were second with good plants, also, of Mademoiselle Julie Daran, John Hopper, Souvenir d'un Ami, Madame Damaizin, Anna Alexieff, Lord Raglan, Charles Lawson, Virginal, Madame Villermoz. Mr. William Paul had some large plants of Madame Clemence Joigneaux, Madame Alfred Rougement, Jean Goujon, Beauty of Waltham, Souvenir d'un Ami, John Hopper, and Le Rhone, and also a fine single plant of President. Finally, Messrs. Paul & Son had some boxes of cut blooms, very beautiful, comprising most of the old favourites—Pierre Notting, Charles Lawson, Sénateur Vaisse, Gloire de Dijon, Maréchal Vaillant, Anna de Diesbach, Charles Margottin, Charles Lefebvre, Madame Charles Craplet, Lord Clyde (very good), Maréchal Niel, Duchesse de Medina Cœli (very fine), David Pradel, Virginal, Gloire de Dijon, Louis XV., Eugène Desgaches, Madame Charles Wood, Maurice Bernardin.

Notwithstanding the mild winter, there is evidence on all sides that we are having a late spring; and hence Auriculas, which will not submit to forcing by any means, were shown in limited numbers, there being but one competitor in each class. Mr. C. Turner had, as usual, excellent plants. In his twelve were Lightbody's Fair Maid, Maclean's Unique, Lightbody's Admiral of the Blue, Taylor's Glory, Page's Champion, Traill's Florence, blue self; Traill's General Niell, somewhat foxey in colour; Gaines' Lady Richardson, paste a little too thin; Lightbody's Countess of Dunmore; and Read's Miss Giddings, rough. Mr. James had Conqueror of Europe, Smith's Mrs. Smith, Smith's Ann Smith, Oliver's Lovely Anne, Lizzie Stuart (like Lovely Anne), Taylor's Glory, Warris's Union, Sims's Eliza. Of Alpines the display was equally small. Mr. Turner had Brilliant, Emperor, Star, Attraction, Ilector, and Conspicua, all seedlings except the last. Mr. James had Beauty, Leigh Wilson, Brilliant, Lilac, and Novelty.

Polyanthes were also exhibited, but not named. Pansies were also exhibited by Mr. James, and comprised Black Douglas, Mrs. H. Hooper, Rev. H. Dombain, Father Gavazzi, Seedling (poor), Mrs. White, Perfection, Ladyburn Beauty, Alexander Tait, Beautiful Star, Mr. J. Ramsay, Czar, David Inglis. They were not very fine, and out of twenty-four blooms there were sixteen dark selfs, most of them very much alike.

Roses formed one of the chief features of the Exhibition, and attracted a large number of admirers as usual. It gave one a taste of coming pleasures, and showed, too, what I suppose pleases all of us—that one's judgment as to the Roses of past seasons was not very far off—as well as could be gathered from flowers grown under glass. We shall see more of them as the season advances, and then be better able to "make our book."—D., *Deal*.

WEEKLY SHOW, April 14.—There is a more than usually extensive exhibition this day, which was attributable to the presence of Mr. William Paul's beautiful pot Roses and Mr. Turner's magnificent Azaleas, which had been let from the spring meeting of Thursday. The classes for which prizes were offered were—First, for eighteen bulbs in flower, the first prize being taken by Messrs. Cutbush & Son, and the second by Mr. Bartlett, while an extra second was awarded to Mr. Young. Second, for miscellaneous plants in flower, Messrs. Cutbush received the first prize, and Mr. Young an extra first. An extra first was also awarded to Mr. William Paul for his collection of Roses in pots, which were still in fine condition. There were also collections of miscellaneous plants exhibited by Messrs. J. & C. Lee, of Hammer-smith, which received an extra first, and by Mrs. Hooke, of Fulham, and Mr. Bartlett.

At the usual fortnightly meeting to be held this day, we are informed that *Dendrobium MacCarthus* will probably be exhibited. This beautiful species is found pendent from the trunks of large trees in the forests of Ceylon, where it is known to the natives by the name of "Wis-sak-mal," the signification of which is Rainy-mouth Flower, or May Flower. A plate and description of it were given in "Curtis's Botanical Magazine" in 1855.

AMARANTHUS TRICOLOR.

In reply to a query put by one of your correspondents (page 257), I beg to say that in 1863 the gardener of Count Borromeo, of the Isola Madre, Lago Maggiore, gave me some seeds of the *Amaranthus tricolor*, which, sown in pans and placed at first in moderate heat, made strong plants about a foot in height, and remarkably effective from their brilliant foliage. Last summer the heat and want of rain caused the plants to lose their colour more quickly; but with shade and water they may be kept bright late into the autumn.—W. C. W., *Saltford*.

THE HORTICULTURAL DINNER proposed to take place during the week of the International Horticultural Exhibition continues to progress favourably, and the following names have

been added to the General Committee—viz., Dr. Masters; Messrs. Bull, Barnes, Barr, Fleming, McKenzie, T. Osborn, Standish, and Turner. At a meeting held on the 9th inst. it was resolved to secure St. Martin's Hall for the dinner.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE March Meeting of this Society (in the absence of the President), was presided over by W. W. Saunders, Esq., F.R.S., one of the Vice-Presidents. Amongst the books presented to the library since the last meeting, was a valuable memoir on the Neuropterous insects of Spain, by M. Pictet, jun.

A very remarkable and extensive collection of Beetles, Butterflies, and Moths, was exhibited by Mr. Stevens, collected at Hakodadi, in Japan, a great number of which could scarcely be distinguished from the common English species, the whole having a very European character, there being but a very few exceptional species of the Indian type. Amongst the Beetles there were only representatives of two genera not European.

Mr. Tegetmeier also exhibited a collection of Lepidoptera, from Nagasaki, in Japan, but this series was composed of larger-sized species, much more oriental in their character than the former.

Mr. S. Stone sent for exhibition some nests built by workers of *Vespa sylvestris*, after the original nest, with the queen, had been removed. These nests were very bungling and irregular in their form, showing that the workers needed the superintending attention of the queen, or master builder. A curious fact had been observed by Mr. S. Stone in connection with these nests—namely, that the cells contained eggs. Mr. Tegetmeier stated that the same fact had been also well ascertained to be the case occasionally with the workers of the hive Bee, but the eggs were laid irregularly, several in a single cell, and they always produced male insects. The physiological cause of this strange fact, as also of the power of the queen Bee to deposit male or female (*i. e.*, workers'), eggs at will, was explained by Professor Westwood.

Mr. McLachlan exhibited a twig of Mulberry collected at Saugor, in India, by Captain Alexander, on which were arranged, in three rows, about sixty eggs of a species of *Asecalaphus* (a genus allied to the Ant Lion), from which some of the young larvae had been hatched. Geoffroy had stated that a female of this genus had deposited several large eggs, but he had not obtained the young from them. The preparatory states of the genus had, however, been more recently published by the late Rev. L. Goulding, and by M. Braner.

Mr. Pickard Cambridge, exhibited an extensive collection of insects of all orders formed by himself in Syria, Palestine, the Styrian Alps, &c., and which were intended for publication in the work undertaken by Mr. Tristram, on the Fauna and Flora of Palestine, as part of the great work projected by the Palestine Exploration Society.

A valuable Memoir, by Mr. Edward Saunders, was read, containing the description of a considerable number of new species of *Buprestida*, collected by the late M. Mouhot, in Siam.

A note from Mr. Groser was read, confirming, on the authority of Rev. Leonard Jenyns, Mr. Doubleday's statement as to the noise made by the Death Watch. A conversation took place relative to the insects found in amber, copal, &c., founded upon Dr. Welwitsch's recent communication to the Linnæan Society.

TEMPERATURE-RECORDING APPARATUS.

(Continued from page 244.)

I HAVE a few more remarks to make on the above-mentioned apparatus which more particularly concern those who, possessing a maximum thermometer, find that the mercury does not always divide uniformly at the obstruction *o* (see page 243), but separates sometimes above, sometimes a little below, the compressed portion of the tube. Should any person possess such an instrument, and be unwilling to have it altered so as to cause the mercury to divide with accuracy at a given point, which alteration can be very easily effected, I will show him how he can learn with certainty the maximum temperature between any given times, though he himself be absent. Instead of arranging the thermometer in a vertical position, as shown in *fig. 1*, page 243, the instrument must be suspended exactly as it would be placed by an observer should he wish to know the maximum temperature—*i. e.*, in a horizontal position. When the alarum weight descends the mercury runs down to the end of the tube (see *fig. 2*), and thus the greatest temperature of the greenhouse between the time of setting the alarum and the descent of the weight, say midnight, is learnt in the morning. The temperature-recording apparatus would also, I believe, be of some service to those who wish to keep a register of maximum heat, or of temperature at any fixed time, but who are, perhaps, unable to be present at the usual time for observation.—X., *Surrey*.

PLEROMA ELEGANS CULTURE.

The fine, purple-tinged, yet intensely blue flowers of this plant render it interesting and valuable, as it furnishes flowers of a colour much wanted in greenhouse plants. It is not exactly a greenhouse plant, nor will it thrive in a stove, but requires a warm greenhouse. In a cool greenhouse it acquires a starved, brown, sickly aspect, and in the stove it grows too straggling, and being kept continually in a state of growth the wood does not ripen sufficiently for blooming well. The flowers are produced on the wood of the previous year, and to have that well ripened is the greatest point of all; for unless the previous year's growths are well ripened the flowers at their points will be few.

It is propagated by cuttings, and early in April is a good time to put them in. Side shoots are the best; they should be 3 inches in length, brown and firm at the base, and the points green, or in the condition of the wood when about three-parts ripe. They are to be cut transversely below the lowest pair of leaves, which, as well as the next pair, should be removed. The cutting pot having been half filled with crocks, and a little moss placed over these, the remaining space should be filled up with sandy peat, with a layer of silver sand at the top. Insert the cuttings round the sides of the cutting pot, and place it inside one of larger size, keeping the rims of both level, and filling up the interval between the two with crocks to within an inch of the top, and then to the level of the rims with silver sand. Give a gentle watering, and place the cuttings in a bottom heat of 75°, covering with a bell-glass when the leaves become dry. Shade from bright sun and that only; tilt the bell-glass a little on one side, or, better still, take it off at night, replacing it in the morning. Avoid the necessity of watering the cuttings by keeping the atmosphere moist, but the sand must be kept just moist. Continue this treatment until the cuttings are struck, then gradually expose them to light and air.

The cuttings having been struck pot them off singly in small pots, draining well, and using a compost of turfy sandy peat three parts, turfy light loam one part, and one part of silver sand. After potting they should be kept close, and shaded for a few days until established, giving a gentle hewing of water morning and evening, but avoiding watering as much as possible. When established remove them to a cold pit, giving the plants a position near the glass, and where they can have abundance of air. They should be housed in good time, and have a light and airy situation in a house having a temperature of 45°, and not exceeding 50° from fire heat. In April they should have a shift into pots 4½ inches in diameter, and now, unless very carefully watered, they will not take to the new soil kindly; a gentle syringing will be better on sunny afternoons than too much water at the root. Unless the plant grow up without showing side shoots it should not be stopped; but if it grow up with a single stem take out the point of the shoots a fortnight after potting. This will induce side shoots, and unless feathered at the bottom it is best to throw the plant away. The side shoots, if inclined to grow erect, should be tied down, and when the leader has broken choose the most likely shoot for a new leader, and let it make six joints, then take out its point. The strong side shoots are to be stopped at the third joint, and so on repeatedly until August, when stopping is to be discontinued, the plant exposed to more air, and less water given at the root. This treatment will assist the ripening of the wood; for, though the plant is not expected to bloom the following year, it will winter better, be more healthy, and shoot more strongly and regularly, than one kept too warm and moist, and allowed to become large and straggling before being stopped.

The plants will by the following April be stiff and bushy, such as can be had from a nurseryman in 4½ or 6-inch pots, at a much less cost than any gardener can propagate them. The plant should be potted early in April from a 4½-inch pot into one 8 inches in diameter. This is certainly a large shift, but we must bear in mind that our plants are young and strong, and that they are impatient of either small or large shifts. It is well to give a good shift and nurse the plant afterwards, for if small shifts are given it follows that the plant must be nursed for a time after every shift, no matter how small. Drain the pot to one-fourth its depth, and on the crocks place from one-half to three-quarters of an inch of pieces of charcoal about the size of a pea, and on this again a very thin layer of moss. The pot, bear in mind, must be clean inside as well as outside, and not hardburnt. The soil to be used may consist of three parts sandy heath mould, one part yellow loam from rotted

turns a year old, and one part of pounded charcoal not larger than a pea, with the dust sifted out, and silver sand in equal quantities. The peat and loam should be broken tolerably fine, but not sifted, and the whole should be well mixed. Before turning the plant out see that the soil is thoroughly moist, but not newly watered or very wet; turn out the plant, pick away the crocks, and loosen the sides of the ball a little in order that the fibres may the more readily lay hold of the fresh soil. Pot with the compost neither wet nor dry, keep the neck of the plant slightly elevated in the centre of the pot, and press the soil pretty firmly around the ball. After potting give a gentle watering, and until the roots are working freely in the new soil afford slight shade from bright sun, and sprinkle the plants overhead two or three times a-day in place of frequent waterings at the root. Just keep the soil moist and no more until the roots are working freely in the fresh soil. The temperature now should range from 50° to 55° at night, and if there is a late Peach-house no better place could be found, for, from the air circulating constantly and the moisture kept up by syringing or otherwise, it will cause the plants to grow freely and strongly.

When the plants begin to grow freely stop the strong shoots to three joints, but let those which are weak remain untouched. Commence training the plant at once by tying or pegging-down the shoots, so as to have it well furnished quite down to the rim of the pot. The stopping is to be continued up to August, for the plant is not intended to bloom in the following year. We will, therefore, if the roots have reached the outside of the pot, shift the plant into a 12-inch pot by the middle of June, proceeding as before, with this difference, that it is to be placed in a cold pit and kept rather close, shaded, and frequently syringed overhead until the roots are working in the new soil, when more air should be admitted, continuing syringing overhead on the evenings of hot days up to the end of August. By this time the plant will have made short little shoots from the last stopping; to harden them more air should be given, and the supply of water diminished, but never so much as to affect the foliage. Water, whilst the growth is forming, will require to be plentifully given. The plant should be housed by the middle of September.

If two plants or sets of plants can be grown, they may be treated differently. One plant or set of plants should not be potted in June nor stopped after that time, and should receive a syringing on bright afternoons up to the end of July, when a cold pit will be a more suitable place. Tilt the lights back and front, and by the end of August lessen the supply of water, and this, with air and light, will ripen the small shoots, and by the middle or end of September the plant will need to be placed in its winter quarters. If the wood be well ripened this plant or set of plants will bloom in the following year, and the other, potted in June and stopped up to August, may do so also; but this will depend on the wood being ripened and the shoots not being stopped in spring. If the plant is not wanted as a specimen for summer shows, or is not required to bloom until the following or fourth year as a plant (the fifth from the cutting), we have to pot it in a 15-inch pot. At this potting use peat and loam in equal portions as the staple of the compost, with one-fourth of charcoal and silver sand in equal parts. With the same treatment as given the year before, the plant will grow freely; stopping must then be commenced, and it should be continued up to the end of June, syringing overhead daily to keep down thrips, to which the plant is liable. In June, if the soil quickly becomes dry, which shows the pot to be full of roots, clear, weak liquid manure may be given once or twice a-week from that time up to the end of July. The plant should then be set in a cold pit, the syringing discontinued, and air given back and front, and by the end of August the supply of water should be gradually diminished, so as to reduce it to a minimum by the third week in September. Remove the plant then to a light and airy part of some house where there are no creepers overhead, and no plant so near as to crowd it and prevent its receiving light sideways. Give air plentifully, but avoid giving it in front when the external atmosphere is frosty, affording at such times a change of air by opening the back lights instead. The temperature should be 45°, and not exceeding 50°, from fire heat, and as to the watering, confine that to giving enough to wet the soil when it exhibits signs of dryness.

As to training the plants, I have an inclination for cones or pyramids, and to secure these it is necessary that the plant have a leader, which will involve a change in the system of stopping. The shoots at the upper part of a plant are invariably the strongest, and if these be stopped as closely as those

lower down they will always be strongest. Now, to check this, the upper part of the plant should not be stopped beyond four or six joints at a time, shoots midway up the plant to three, whilst those near the rim of the pot will hardly need stopping at all. All weak shoots are not to be stopped unless they become straggling or otherwise interfere with the formation of an evenly-balanced specimen. The shoots will need tying down and regulating so as to have every part furnished. It is well, however, for those shoots tied horizontally if the ends curve upwards a little, for horizontal shoots do not grow nearly so strongly as those more erect.

In April an increase of from 5° to 10° by the end of the month will tend to encourage the swelling of the buds, water being given corresponding in amount to the increase of temperature and solar heat. When the plants are in bloom their beauty will be prolonged by placing them in a cooler temperature, and shade from sun is indispensable.

After flowering let the plants have a fortnight's rest by keeping them cool and dry, then prune or cut back the growths all over the plant rather closely, leaving, however, enough of the last year's growths for new shoots. If the plant is to bloom in the following year it must not be cut-in much; the pruning should, therefore, in this case be confined to removing or short-

ening irregular shoots. Subsequently, growth should be encouraged by a close and moist atmosphere, and shading from bright sun. Pot, if necessary, at once if the plant is not cut-in much, but not until the growths have attained an inch or two in length if the plant has been cut-in hard, it being then shaded and syringing overhead until the roots are working freely in the fresh soil. Afterwards admit air and light, exposing fully (still keeping the lights on), in August, and housing in good time for the winter.

For old plants use a compost of equal parts of turfy peat and loam, well turned and aired, chopped with the spade; and to this may be added one-third of leaf mould, old rotten manure, and bits of charcoal, in equal proportions, and one-sixth of silver sand. During growth, and when the flower-buds are showing and swelling, manure water may be given at every third watering; but not when the wood is ripening and in winter. The great point is to have the young wood well ripened. To have very fine specimens it is well to have two sets of plants, so as to allow one year's rest for preparation, whilst the other is brought on for blooming.

If aphides attack the plant fumigate with tobacco; and if thrips appear syringe freely when growing, fumigating with tobacco when syringing cannot be practised.—G. ABBEY.

WINTER CUCUMBER-HOUSE.

Your correspondent, Mr. O'Donnell, has given in your last Volume, page 524, a description of a winter Cucumber-house, and as he thought it would be beneficial to some of your readers to have a description of other houses, I shall proceed in a simple manner to give the particulars of one that has been erected about five years, and has afforded me great satisfaction.

It is a span-roofed house, as will be seen by the accompanying section, and is 48 feet long by 11½ feet wide. The height is 8½ feet to the ridge. There is a bed on each side, with a walk in the centre. I have a partition in the centre, which divides the length into two parts, which gives me the advantage of growing Cucumbers all the year round. In the summer I grow Melons in one part and Cucumbers in the other.

It is heated by a large square boiler, of which I will give a description at some future time. There are four four-inch pipes for hot heat in each house, two flows and two returns, and one four-inch flow-and-return under each bed for bottom heat. In each house there are four evaporating-troughs attached to the pipes to give moisture when required. Air is admitted at the top and sides by ventilators 18 inches wide by 1 foot deep.

The plan I have sent is on the scale of a quarter of an inch to the foot. The pipes are represented by small circles; *b b*, beds; *w*, walk; *c c*, chamber; *v v*, ventilators; *s s*, iron stays to support the centre of the roof.

In reading your Journal for the last eight or nine years I have at different times come across inquiries made respecting the construction of trellises. I have adopted a plan which may not be new to your readers, it is simply Barnard and Bishop's galvanised wire netting (commonly used for the purpose of making sheep-folds), strained on frames made of small round iron.

The mesh is sufficiently large to allow the hand to pass through for the purpose of training the plants. This netting is stretched about 15 inches from the glass on small crooks fastened on eyes, which are screwed to the rafters. This is very convenient, as the netting can be removed at any time when the house requires cleaning or painting. I think this preferable to wooden trellises, which are adopted in a great many houses.

Mr. Veitch, of the Royal Exotic Nurseries, Chelsea, saw my Cucumber-house in January, 1865, and said that the Cucumbers were the best

he had seen for the season, some being 18 inches in length or, I may say, even more. I think it is more economically constructed than the house described by Mr. O'Donnell; but still I must allow that that has one advantage over mine, which is the inner door and partition at the entrance, which excludes the cold draughts on the outer one being opened.—W. HALLETT.

GRAPE BUNCHES BECOMING TENDRILS—VINES BLEEDING.

THE Vines from which the enclosed specimens were taken are Muscat of Alexandria and Canon Hall Muscat. They have only been planted about seven years, I believe, and I think they have been heavily cropped, as I found on taking charge last summer that some of them were carrying seventeen or eighteen bunches, and scarcely any of the Vines are more than 1¼ inch in diameter, some not more than 1 inch. They are in a good-sized well-constructed house, heated by hot water. The house was closed in the end of January, heat applied on the 1st of February, not much, and the temperature kept at about 45° at first, and gradually increased, with plenty of moisture; the highest it has ever been since starting was 73°. I give these particulars in order to make it plain what sort of treatment the Vines have had for the last few months.

Among other Vines in a late viney we have two West's St.

Peter's. One day in February, when the Vines were being cleaned, one of the St. Peter's was left hanging, partly tied to the rafter, and the end resting on the floor all night. In the morning seven or eight of the topmost spurs were bleeding profusely. I crushed the ends with my teeth and bound them tightly up with a bit of fine wire, which stopped the bleeding at once. There has not been any heat on the house since the last Grapes were cut in January, only enough to keep out frost, in fact, it was so all winter. The buds are pushing now 1 or 2 inches long, and about a fortnight ago almost every Vine in the house commenced bleeding. I give a little heat now, so as to bring them on quietly after the first house. I do not know what sort of borders they are in, but am told these were well made. In the early house the Vines are planted inside the house; in the late one they are planted outside. Both borders

are covered with litter; in the early one with a thickness of 7 or 8 inches, in the late one of 4 or 5 inches.

Will you give me your opinion in the next Number as to what is the cause of the bunches running to tendrils in this way; and also what is the cause of the first bleeding of the St. Peter's, and the later bleeding of the whole lot?—E. VISENY.

[You have, apparently, acted quite right with the Vines. The cause of the bunches running to tendrils is most likely previous over-cropping and the roots being too deep, or having too much moisture in this wet season. We have some on two Muscats, though we had lessened the heads considerably; but they had borne immense crops for a number of years, and not received much countervailing nourishment. If the roots are not too deep the Vines will most likely recover themselves in another season. If you think the roots are rather deep, the Vines will require extra firing in the autumn. As to bleeding, we do not think in the case of the West's St. Peter's it was owing to the top of the shoot being bent near the ground. We attribute it and the bleeding in the late house to the mild winter, and the rather active state of the roots in the border. As a general rule, the sooner Vines are pruned after the fall of the leaf the better. In the case of very late Vines, where we could not prune owing to the Grapes, it is a good plan to cut out all the buds not wanted, before one is able to prune. This matter of bleeding is referred to in "Doings of the Last Week."]]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as the principal crops are in the ground, and the supply of dung to serve for the season has been wheeled on the principal quarters, proceed to make good any part of the Box edgings, either by taking the whole up and replanting, or filling up such blanks as may have occurred during the past year. Thrift and other similar edgings require taking up and replanting every two or three years. Although Box edging looks neat and helps to set off a kitchen garden, yet on account of its harbouring slugs and the annual repair which, even with the greatest care, it always requires, we prefer stone or earthenware for bordering, which though more expensive in the first place, will in a few years repay the additional outlay, besides the appearance of stability which the stone or earthenware edgings give to the walks. After the edgings are put in order, turn over or regravell the walks, and after rain let them be well rolled till they again become firm; the garden will then present through the season a clean well-regulated appearance. The minor paths or alleys to be kept in an equally tidy state, for which purpose place scrapers at each intersection of the paths or walks, or, in fact, wherever they appear likely to be required. *Beans*, make a sowing of Taylor's Large Windsor, to succeed those sown in the end of last month. *Broccoli*, if a sowing of Snow's Winter White, the Walcheren, and Knight's Protecting has not yet been made, it should be done without delay. *Brussels Sprouts*, make a good sowing for winter use. *Cabbage*, a sowing of the Champion Early Dwarf should now be made to produce plants for winter and spring use. *Cardoons*, the seed may now be sown in trenches where the plants are to remain. When preparing the ground the manure to be covered with about 3 inches of soil. Place three seeds together, 14 inches apart. Only one plant, however, must be allowed to remain at each spot. *Cucumbers*, keep the shoots well regulated, as on this particular their fruitfulness in a great measure depends. Seed should now be sown to produce plants for ridges. *Mushrooms*, in making beds to produce through the summer, a portion of loam should be mixed with the dung to give greater solidity to the bed. *Nasturtiums*, sow. The seed if gathered when quite young and pickled in the usual way forms an excellent substitute for capers. Trained against trelliswork the plant is highly ornamental. *Potatoes*, if the main crops are not yet in, lose no time in planting them. *Savoy*s, another sowing may be made for a late crop. *Turnips*, make another sowing.

FRUIT GARDEN.

A portion of the protecting material should be removed from Peach, Nectarine, and Apricot trees. Do this gradually, that the bloom may not suffer by a too sudden exposure. When canvas screens on rollers are employed, of course they are rolled up by day, and let down each night. If the nights, however, are warm, they need not be lowered quite down, as a little extra air by night will be more beneficial than otherwise to the bloom. Where spray or netting is used, and which could

not conveniently be removed daily, a part may be taken off at once, only keeping it on hand in case a return of severe weather should render its use again necessary.

FLOWER GARDEN.

Showery weather should be taken advantage of to complete the planting of deciduous trees and shrubs without delay, and likewise of any evergreens left unplanted from the autumn, as from the present time to the end of the month is the most suitable season, next to the autumn, for removing most kinds of evergreens. In planting avoid exposing the roots to the sun or drying winds. Mulch immediately after planting, to prevent undue evaporation from the soil as well as to save watering. A good watering overhead with the garden-engine on the evenings of bright days will prove of great use to newly-planted evergreens, and when the plants are large, the stem and some of the principal branches should have haybands tied round them, which, being damped once or twice daily, will keep the bark moist and facilitate the flow of sap. Proceed with the planting of hardy climbers against walls, trellises, and verandahs. Select some of the most showy species, such as *Caprifolium*, *Wistaria*, *Bignonia*, *Clematis*, *Tecoma*, &c., and introduce amongst them some of the strong-growing *Noisette*, evergreen, and hybrid climbing *Roses*. If it is desirable to hide some disagreeable object from view, we would strongly recommend the following *Roses*—*Rampant*, *Donna Maria*, *Triomphe de Bolwyler*, *Madame d'Arley*, *Garland*, *Queen of the Prairies*, and *Baltimore Belle*; these are in every respect suitable for this purpose, being rapid and strong growers and abundant bloomers.

GREENHOUSE AND CONSERVATORY.

In watering pot plants, great care should be bestowed, as it is an important process; too much, too little, or an injudicious mode of application being equally fatal to high cultivation. Very many plants are seriously injured at the periods of shifting or potting off, by improper watering. A very fine-rosed watering-pot, and slight applications of water, at intervals, soon after potting, constitute the best way, as a general maxim, to penetrate the mass, and to cause the particles of soil so to arrange themselves, that the atmospheric influence shall be somewhat modified, but by no means intercepted. There is, however, no good reason why all plants should be watered immediately on shifting them. When a plant has no ball of earth, the water should, of course, be made to penetrate the whole mass, in order to prevent desiccation, which would sometimes ensue through extreme porosity in the new soil. When, however, the subject is a plant with a hard ball, a steeping overhead in water for an hour is a preferable course. After this, frequent syringings or waterings with a fine rose will be the soundest policy for a week or two. Proceed at once with the staking and tying-out of plants requiring such assistance. Turn each plant frequently round, that it may not become one-sided. *Epaerises* and spring-flowering *Heaths* will bear close pruning after flowering is over. *Correas* that have been flowering during winter should now be rather closely pruned, and kept in-doors all summer, when they will take the place of *Fuchsias* after September. The cuttings we advised to be struck for a stock of winter-flowering plants will now require potting off. As it is not desirable that these should be grown to a large size, keep them rather short of pot-room, a hot-water pit will answer best for growing these and similar plants. The plants can then be brought close up to the glass, and by a little attention will form stout, bushy subjects, with well-ripened wood by the autumn, and they may then be brought into bloom at pleasure.

STOVE.

Pay due attention to the watering, shifting, stopping, &c., of stove plants in general. Make cuttings as they can be obtained in a young state of *Geissomeria*, *Plumbago*, *Eranthemum*, *Justicia*, *Clerodendron*, *Vinca*, *Euphorbia*, *Brugmansia*, *Begonia*, *Thunbergia*, &c., in order to keep up a succession of clean young stock. Syringe freely in fine weather; shut up early with solar heat, give air freely, and fumigate with tobacco in due time.

PITS AND FRAMES.

Cultivate plenty of *Heliotropes*, *Aloysias*, and the sweet-smelling *Pelargoniums*. Part the roots of *Eurothera macrocarpa*, or by-and-by cuttings of the shoots may be made when about 3 inches long. They soon root if put in a little heat. Increase *Gladioluses* and *Lilies*, as they are very useful in relieving dark masses of foliage. *Cistuses* and *Helianthemums* should also be had in abundance.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

VERY much the same as last week, the heavy rains making the ground too soaked to do much. Prepared for fresh beds of pot-herbs, and sowed such kinds as Basil, Sweet Marjoram, Ice-plant, &c., under glass. Sowed also in a mild hotbed Capsicums, Tomatoes, picking Cucumbers, Vegetable Marrows, &c., and put in some cuttings of Cucumbers, as we are always rather short of desirable seed. Turned a lot of Kidney Beans from five-inch into ten-inch pots, and put a row of them in the orchard-house, where we think they will be safe. Planted more in five-inch pots, five Beans in a pot; they will be turned out after they are some inches in height, and be protected with a few laurel branches. We find, even if the ground were more suitable, it would be of little use planting them out of doors, as the pheasants are so keen in looking after all fresh-stirred ground that we might just as well have forty fowls brought to the kitchen garden from the farm.

Planted-out more Cucumbers, as detailed last week. Those in our earliest three lights, though healthy, are showing the effects of hard early cropping. Early Cucumbers are an object, and hence the first crop is frequently injured by heavy cropping. When it is desired to keep the same plants long in bearing, they should produce but sparingly, until the vines of the Cucumbers pretty well fill the space allotted to them in the frame or pit. Like almost everything, if they bear heavily before they have made plenty of growth, they are apt to produce but little for some time afterwards. Amateurs should also recollect that a large Cucumber, from 16 to 24 inches in length, at an early period and from young plants, will injure the plants more than four or half a dozen Cucumbers crisp for the table at from 7 to 8 inches in length. To ease young plants we frequently cut the stalk of the Cucumber half way through, or more, as then it keeps more crisp than when cut, and injures the plant less, though when covered with leaves of Broccoli or Rhubarb Cucumbers will keep well some days in a cool place. Particular people like them best cut only a short time before they are used. When the most fruit possible is wanted from young plants in an early frame or pit, it is advisable to follow with another bed from which little shall be cut until the plants are established, and then, when they are in full bearing, either give a rest to or renew the first bed with fresh plants. This will explain how some persons find their Cucumbers standing still after yielding fruit from small young plants. They must have a few weeks' rest to recruit their energies, and then most likely they will do well enough. "W." has a deep pit, plenty of bottom heat and top heat, but his bed is 5 feet from the glass, and he thinks that would not do for Cucumbers. We have not a doubt of its doing first-rate, and without setting up the plants on reversed pots. We would advise growing the plants in pots, and without stopping, training them to one stem until they were nearly 4 feet in height, then to turn out the plants into the bed, and in a few days stop the plant by picking out its point. All the buds on the stem below the trellis should be picked out, and the shoots trained as they break, to a trellis 15 inches from the glass. Such plants are more easily kept from woodlice, &c., than those grown on a bed, and, as a general rule, they will be more fruitful.

Cucumbers and Vermin.—The strong plants in the frame that were eaten and spoiled did no more good. The process resorted to, as detailed some weeks ago, seems as yet to be successful with the fresh plants turned out, which now half fill the box, and are showing fruit. We may as well repeat the process. Earth was beaten firmly all round the inside of the box, and from 4 to 6 inches above the level where the box rested on the dung-bed. This was to prevent any steam or smell coming in from the outside—a good plan where fresh rank material is used for linings. This done, the lower part of the box outside, and the bed on which it rested, were smeared with coal tar, and a little was sprinkled farther down on the bed. Litter was then placed over it, so as to cover the box considerably outside. When mice and rats find their way into such beds, they seldom go much lower down outside than the bottom of the box. The heat of the linings would keep the tar there in a moist state, and so long as it is so none of them will willingly go near it. At any rate, they have not meddled with this bed since. We would, however, strongly urge upon any who would try this preventive to make sure that none of the fumes of the tar penetrate into the frame or pit, or that will be as dangerous as the rats themselves. A keen amateur, to make assurance doubly sure, plastered some tar inside of his frame, after reading our previous notice, and

was inclined to lay the blame on us for the unfortunate results, though then, as now, we were particularly urgent that no fumes from the tar should pass inside.

Moles and Tar.—Moles have been wonderfully plentiful and active this season. In fields, in pastures, pleasure grounds, kitchen garden, and in slight hotbeds for Radishes, Carrots, Potatoes, &c., they have been hard at work. In common fields and pastures we doubt very much if they do not do more good than harm. They put out of the way lots of worms, wire-worms, &c. Their deep runs help to drain the land, and so long as their galleries are deep they do little or no injury to vegetation, and several times in our experience, when they have so taken possession of a little meadow, as pretty well to cover it with their heaps, the spreading of these has acted as a valuable surface-dressing in spring, and the interfering with these heaps is apt to give the mole offence, and he decamps for a while, until it would be advantageous to bring some of the subsoil to the surface again. In pleasure grounds he does interfere with high keeping and neatness, and more especially when the runs are just under the surface, the whole rendered visible by a slight rounded ridge, underneath which you may safely calculate the roots of grass are so cut as to prevent you with narrow, withered spaces in summer, if you do nothing to prevent it. Well, having tried in our hotbeds gentle deterrents which would not keep moles out, if already comfortably nestled there, we were obliged to trap some in the usual way, and the less of the scent of the hand there is about the trap the more easily will the mole be caught. As respects the pleasure ground and gardens, however, we were alike kind enough to the moles, and selfish enough as regards ourselves, merely to desire them to shift their quarters, and let others trap them who were fonder of the job, and this object we think we have effected by making openings with a trowel, in the shallow runs especially, pouring into the openings a little tar, and then shutting them up. We have scarcely observed a new run since. The mole is such a cleanly creature, that the scent and touch of tar are too much for his delicate sensibilities.

Peas, Pheasants, and Tar.—This will almost appear a tar article, but the simple hint may be serviceable to some. Until this season we suffered comparatively little from pheasants. From a small quarter of winter Greens it has not been uncommon lately to start twenty in a morning, and they managed to obtain more of the hearts of Brussels Sprouts, &c., than those for whom they were intended. We knew of old how fond they were of Peas and Beans. We began to think we should have to go through the labour of raising all such crops in various ways, and planting them out when 6 or 9 inches in height. We know very well what would stop them—a rather close-meshed wire netting, in a somewhat semicircular shape, the open base a foot in width, and from 9 to 12 inches in height to the dome of the arch. If the mesh were more than 2 inches across the pheasants would reach the Peas and the young growth through the meshes. If it is from three-quarters of an inch to an inch, there is the risk that they would get their head in and not get it out again. Such wire guards could either have iron feet to go in the ground, or be fastened to stakes; and the wire if galvanised would last a long time, be useful for many purposes besides Peas, and could be put away in little room when not in use. Common cord netting with meshes not less than an inch across are less useful, as the pheasants will tear them, and find their way underneath and, what is a more serious matter, will often hang themselves. We could have used common netting, but we have a vivid recollection of seeing half a dozen beautiful cock birds that had committed involuntary suicide in a net thirty years ago. The gardener and the keeper wisely kept the matter to themselves; and the latter, being an obliging man as well as a faithful servant, turned out every morning early for a week, and made the pheasants so uncomfortable close to the garden, that they went farther afield for their chief feeding grounds. The recollection of this hanging in the nets kept us from using them, and until the last sowing a fortnight ago not a single Pea or Bean was left of all the previous sowings out of doors. We had sowed in the usual way, only covering with rough ashes as being disagreeable to small birds and mice; and then we laid firmly along the rows branches of larch, &c., pretty close in texture, which we meant to remain until the Peas were several inches in height. The pheasants saved us all that trouble, uniting their strength to turn the branches aside, and then clearing the rows as they went.

Our last sowing, a fortnight ago, has as yet remained undisturbed. We based our operations on the proud cleanly

character of the bird, and resolved that he should meet with enough of nastiness before he reached our Peas. We sowed and covered as formerly, placed the branches along the rows, then stretched a stout string about a foot above the rows, fastened pieces of paper and rag to the string, smeared the string, paper, &c., with tar, and shook some tar, with a brush, over the branches, scattering a little on the ground along the rows, the tar being heated over one of the furnaces to make it shake easily from the brush. This will smell strong, and keep rather soft and liquid for a considerable time at this season, and if we find it necessary we can run the brush again along the string. By the time the Peas are up the little tar on the ground will have become rather dry and comparatively scentless, and will not at all affect their growth under such circumstances. The next morning at half-past four o'clock there were the pheasants at their old feeding-ground, elucking defiance, just as if from wall or tree they had seen the fresh seed put in the ground. It was very amusing to see them strut and stare, march and run up and down and round these rows of Peas and Beans, not able to nurse their wrath, but giving free vent to their indignation, as, what with the filthy string above the row and the spattered branches and ground immediately over it, they could not find a comfortable spot on which to employ either bill or claws. During the whole time not a single hole in the rows has been made, and so disgusted did the birds seem on account of being foiled that they almost left off their attentions to a quarter of Broccoli near at hand, where they were not only reducing the leaves into threads, but had pecked the heads in the centre. As tar is cheap enough, something like *Id.* a-gallon at most gas-works, and as heating it will cause it to go a good way, it may be useful for keeping off more enemies to the gardener than pheasants.

Would like to give more air to Peas in pots in the orchard-house, which would cause them to swell and set faster; but in these stormy days we like to bring the one orchard-house on by giving much less air, and this, so far, makes the haulm of the Peas grow more strongly than we care about. That row in pots will yield a fine lot of gathering, and standing as the plants do close to the back wall, they are much stronger and earlier than those planted-out nearer the front, where they do not receive quite so much sun heat.

Sea-kale.—Trenched and enriched some ground for planting-out the roots taken up to be forced. The crowns will be all planted by themselves, and the pieces of roots without buds, from 6 to 8 inches long, will also be planted by themselves. These seldom make such good plants as young plants a year or two years from the seed, and they do not do so well from forced plants as those pieces of roots that are taken up from the open air. All the roots forced, except the latest ones put in, have been standing in dry earth in a shed, so as to harden them off well before placing them in the open ground. We shall get what we want in a week or ten days in the open ground. Here we have an example that litter keeps heat out as well as keeps heat in. We covered some time ago a couple of rows with common pots, filling up the hole in the bottom, and merely covered the pots with litter to protect them and make all dark; but though a few plants are coming on nicely, as a rule this piece covered up is not so forward as other rows fully exposed to the weather. The warmish rains and a little sun have rendered the exposed ground warmer than that merely covered with pots and litter. Of course if there had been any heat in the litter it would have been different. Being deficient of pots we have covered a couple of rows with old wooden hurdles. Pots some 10 inches in height were set along the sides of the rows, on which the hurdles with some branches drawn through them were placed; the spaces at the sides along the pots on which the hurdles rested were packed firmly with litter to keep the light out; and some litter and rough hay were thrown over the hurdles for a similar purpose. The hurdles can be easily held up on one side to cut the Sea-kale as wanted. Plenty of Sea-kale enables the gardener to keep the table well supplied in winter. That which is to be forced should not be cut too late in spring.

Rhubarb will now come fast enough out of doors to dispense with forcing. It is generally plentiful in the markets in this neighbourhood, brought from the south of the island, a fortnight or three weeks before we can have it in the open ground here. Roots, taken up for forcing, when divided and planted-out, will generally be fit for raising again after they have had two summers to grow. Now is a good time to sow, either at once in light land, or under protection, and then to be planted-out in the case of heavier and later soils.

FRUIT GARDEN.

A press of other matter has prevented us getting on with nailing as we wished. In the outside border of the late vinery which is now breaking and growing fast, independently of our efforts to keep the *Vines* back, we removed the little stubble from the border, and scraped off and wheeled away all the black surface soil, chiefly decayed dung, which had been left on all the winter. Then slightly forked the border, as the roots were near the surface, and gave a top-dressing of fibry loam, with a fair dressing of lime and soot, and covered with a couple of inches of horsedung, chiefly droppings. We expected to have renewed a portion of this, and other borders, but could not get at them, nor yet the material in time. Young Vines planted the other year, intending to take them up again, are coming on very strong, so that for this season or more they will take no harm. It is no such easy matter to procure the necessary material for a Vine-border, when made as it ought to be, and though wonders are often seen without drainage or border-making, as at Messrs. Lane's, at Berkhamstead, still it would not do to depend on such modes when the gardener can do better. As a general rule, in all cold, stiff soils, in addition to cross and front drains, we should like the most of the border to be above the ground level, and in addition to concreting the bottom, we would like a foot of rubble between the concrete and the soil, and rough material for this purpose is very scarce in some neighbourhoods. We have done nothing but give a little top-dressing to our old borders for many years, with a pinch of superphosphate or guano at times, the superphosphate being the safest to use; but such dressings we look upon as just serving a temporary purpose.

For various reasons, we generally used to tie the Vines of this late vinery horizontally along the front of the house, and we think they not only broke very regularly, but broke a week or so later, which we were rather anxious to secure, as the house being crammed with a number of bedding and other plants, tier above tier, as soon as the Grapes were cut, we wished to use hardly any fire in this house, except when the bunches approached the blooming period. As the sun was becoming strong by that time, the chief help in fine weather was derived from sun heat, as the house could be kept pretty close after all the hardier plants were removed. For two or three seasons, instead of bringing the Vines down to the front of the house, and tying them lengthwise there, each rod when pruned and washed was suspended at from 20 to 24 or more inches from the glass, and they have uniformly broken very regularly; but, as stated above, rather earlier than when tied along the front pretty close to the glass. This might be owing to the two circumstances, that the Vines close to the front air were in the coldest part of the house, and we could make them cooler still by whitewashing the glass roof immediately above them. For early forcing we think the Vines break more regularly when placed horizontally, or lengthwise along the front of the house. The late vinery above referred to has scarcely ever had a dash from the syringe, except one good washing immediately after the fruit has set. During spring, if for no other reason, it would not have been advisable to have used the syringe on account of the plants growing in the house, some of which do not like to have the sun on them whilst the leaves are wet or moist. *Pelargoniums*, for instance, should scarcely ever have wet foliage presented to the sun's rays.

In earlier vineries proceeded much the same as in previous weeks, stopping, tying, and regulating shoots, and drawing the hand over bunches of Muscat and Sweetwater in bloom. Tied roughly Fig shoots in low pit-house, thinned and stopped. Tied Peach shoots in the Peach-house, and left the best-placed fruit. Disbudded in the first orchard-house, or rather removed the fore-right shoots, and took away and stopped a great many more, not making the trees too bare, however, at first. The fruit has set excessively thickly. No buds dropped from this house, but if more than half of them had fallen there would have still been more than enough to give plenty of thinning as they grow. The bloom has hung a very long time this season. In our early Peach-house we never knew the bloom last such a short time. There was an unusual day's sun shortly after the flowers were open, and in a few days the bloom began to fall; but the fruit set very well notwithstanding, but nothing was required in the way of thinning in comparison to what will be wanted in the orchard-house.

The Vines planted-out in the orchard-house are just moving, the most forward buds being from a quarter to half an inch in length, and just as in vineries and Peach-houses, unless where care is taken to keep them late, they will incline to come earlier

by a little every year. This leads us just to notice "AN OLD FRIEND'S" case, who has neglected to cut back his Vines planted last season in the orchard-house, and which are not very strong, but which he meant to shorten by 5 feet at least, yet he never thought of it until he saw the buds bursting, and now he is afraid to cut back. We have no doubt that Thomson's styptic might even suit his purpose if the Vines were cut back, otherwise they would bleed very much, and be much weakened in consequence. If he do not choose that mode he may manage pretty well in this way:—Begin at the top of the shoot, and as soon as the buds are from half an inch in length rub them off roughly with the finger, going down the stem until you come to the shoot or shoots you wish to leave. When this selected shoot has grown from 20 to 24 inches in length, then, if you choose, you may cut off the old naked disbudded shoots or main stem. If you rub off these short bud-shoots, there will be no bleeding; if you cut them off with a knife there will be plenty of bleeding, in fact, almost as much as if you had cut the shoot in the usual mode of shortening.

Vines Bleeding Unexpectedly.—We have known this take place several times when fresh borders of fibry turf had been made with a good mixture of lime rubbish, boiled bruised bones, &c., which, with a little protection on the border, caused a mild heat all the winter to the roots from the decomposing turf, &c. The Vines were pruned at the fall of the leaf in the usual way, and showed no appearance of anything peculiar until they began to ooze and bleed from every cut about three weeks after they were pruned, and some six weeks before it was considered suitable to begin to start them for forcing. Whenever from the peculiar circumstances such a result may be expected, it is advisable to keep the roots dryish until six weeks after pruning, and immediately on pruning to daub every cut with a thick paint made of white lead chiefly, and a little linseed oil and turpentine. Burning the cut parts and daubing the places with various paints was of little use after the sap began to flow. No doubt styptics would have been used if they had been to be had. What surprised us most was the fact that, with one or two exceptions, the great bulk of the Vines that we last saw under such circumstances, after weeping in this way for fully six weeks, broke, and grew seemingly as strong as if they had never dropped the smallest quantity of their sap. Of course in this and the previous ease of neglected pruning alluded to, whenever the leaves expand there will be no more bleeding from the Vine.

ORNAMENTAL DEPARTMENT.

Our work here has been very varied, and some of it, such as moving shrubs, turfing, &c., had often to be left, owing to the weather. On the front border of the earlier vineries, to which heat has been applied, and which was protected by leaves and litter just slightly warm, a bank was made of the litter back and front, a few hot leaves added, a narrow board placed lengthwise well on the ridge, and on these boards old sashes were laid back and front. Under these were placed a great many scarlet Geraniums potted from boxes into small pots; they were watered, plunged, and the pots covered with leaves, as no more water at the roots will thus be needed until the pots are full of roots. Lots of hardier Geraniums were turned out into an earth-pit, though not so dry as we should have liked the soil to have been. Calceolarias in a pit are now suffering from not being removed, wanting sadly to be from 4 to 6 inches apart instead of 1½ inch. They are a perfect thicket, and have been pretty well exposed of late. Auriculas, showing trusses nicely, should be defended from cold rains and east winds, and if manure waterings are given not a leaf should be touched.

Finished pruning Roses. It is well to defer the tender sorts until late, as then if the most forward buds are injured no harm is done. We have seen all the forward buds of unpruned Roses blackened in March, whilst the buds just swelling nearer the base of the shoot suffered not at all. If these Roses had been pruned in winter, and the lower buds pushed, they would most likely have been ruined for bloom that season. We hear of a good many so injured this season. This is certainly one advantage of not being able to overtake our work as we would wish to do. Planted out lots of Hollyhocks, and divided some of the larger stools. Stools that are too large may have the shoots thinned out when from 4 to 6 inches long; and, with a piece of the older stem attached, if these are planted thickly in a warm place they may be lifted again in early summer, and will bloom late the same autumn. Hardly one will fail in light soil, even in the open air. Potted young Pelargoniums for late blooming, picked Orchid-baskets, potted Gloxinias, and Begonias, and shook Gesneras out of their pots, and set them in

shallow boxes just to begin to move, as the sooner they are started after this the better they do for autumn and winter ornaments. When too wet for general work, mended old sashes and straw covers, made tallies and washed pots, tied up plants, and picked and fresh arranged plant-houses.—R. F.

COVENT GARDEN MARKET.—APRIL 14.

THE demand is but moderate, and last week's quotations have barely been maintained. Dessert Apples are confined to Golden Knob and Non-pareils; Pears to Easter Beurre and Ne Plus Meuris. Pines and hot-house Grapes continue sufficient for the demand. Vegetables are abundant, and of Potatoes there is a heavy supply. New ones bring from 4d. to 6d. per lb.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

INDEX (E. A. P.).—You can have the Index for the last half year if you enclose four postage stamps with your direction, and repeat what you want.

PRONUNCIATION OF BOTANICAL TERMS (G. N.).—Henslow's "Dictionary of Botanical Terms" shows where the emphasis in each is to be laid.

GUANO LIQUID MANURE (H. M.).—Half an ounce of guano to a gallon of water is quite strong enough for watering flowering plants. For kitchen vegetables it might be made fully twice as strong. If you enclose four postage stamps with your direction, and order "Manures, or Muck for the Many," you will have the book sent to you free by post. It contains ample directions about making and using all sorts of fertilisers.

FLOWER-BEDS IN LAWN (L. E. S.).—We cannot depart from our rule not to detail the flower-planting of beds or gardens we have never seen. If you will state how you propose to plant the bed we will readily point out anything in your plan which we think would be objectionable.

SEEDLING AURICULAS (X. Y. Z.).—There is nothing remarkable in your seedling Auriculas. They are, as Alpines, very pretty, but deficient in quality as florists' flowers. The centres of the flowers are not sufficiently bright and circular.

DAISY KNIFE (J. A.).—There is a description and drawing of it in No. 118, New Series, of this Journal. You can have it free by post from our office for 4d. Any blacksmith could make one.

JASMINE NOT EXPANDING ITS FLOWERS (S.).—We think if the plant were to have abundance of air and light, with a position near the glass, plentiful supplies of water, and occasionally applications of weak liquid manure, that the flowers would open another year.

BOILERS (J. Wavell).—We have no doubt that the boiler (saddle-backed), is a very good one; but neither in shape nor setting do we see any difference from those usually employed, except in the two metal plates that pass from the boiler through the flue into the arched brick-work. Such boilers if set low enough will burn any fuel that is presented to them. We are doubtful if the metal plates are of much advantage. If anything happened to the boiler it would be more difficult to take it out.

SALT TO ASPARAGUS-BEDS (M. H.).—It is best applied to the beds during the period of the growth of the Asparagus—that is, from March to September. Wood ashes are chiefly valuable as a manure for the salts they contain, which are washed out if the ashes are exposed to rain. Turnips, Peas, Beans, and lawns are benefited by them if used at the rate of forty bushels per acre.

FLOWER-GARDEN PLANTING (This One). We think your simple planting will look well, but we would omit the Asters, as they will not keep on with the others.

SOWING IVY BERRIES (A Subscriber).—The leaf sent, we think, is an Aucuba leaf, and not a Laurel leaf. The berries of the Ivy will be shrunk or shrivelled by the middle of May, when they may be sown at once. Birds, &c., care little for them after the pulp is gone; but unless for some particular purpose, why sow the seeds at all, when cuttings a foot long would root so soon in a moist shady place?

VINES (A Young Gardener).—The *Frac de la Boulaye*, which you have, is the same as our Prolific Sweetwater, an early white variety, ripening its fruit well in a cool viney. Its fruit sets more readily than that of the old Sweetwater. Your Chasselas de Fontainebleau is our Royal Muscadine.

CUCUMBER (A Constant Subscriber).—For your own use, grow in your hotbed the old Long Pickley. None excels it in prolificacy of good fruit.

AMATEUR'S FORCING PIT (B. Gooch).—Your plan is a very good one, and a much finer and costlier affair than Mr. Atwood's, but furnishing you with the great pleasure of doing everything inside, and in any weather. We presume the ground is solid on which you build your flues, otherwise we would not have raised it, as the stems of the Cucumbers can easily be taken up to the trellis, and a bed for various purposes is most easily managed when the side walls are not too high against the person of the operator. Now, for what we think would easily improve your little house. We approve of your two upright drain-pipes communicating with the tank between the pipes, but we would have more of them to let the heat into the atmosphere of the house without too much heating the soil. The soil, also, at present seems to rest on the flues, as well as the slate covering of the tank, and the roots that touch the flues will be apt to be injured. A very simple plan would be to cover the flues likewise, 3 inches or so above them, with slate or open rubble, allow the vapour from the tank to pass over the flues, and have a small drain-pipe—say 1 to 1½ inch in diameter, with its open end fastened in this chamber, and the other end standing up close to the side wall—say one back and front every 4 feet—and the upper end furnished with a plug, to let a moist heat into the atmosphere of the house at will. This is merely a little matter, and if you adopt it, we should like to know with what result. Both you and Mr. Atwood have dissipated the prevalent idea that Portland cement would not stand dry heat. Mr. Robson used to have houses heated by round pipes thus formed of cement.

AMATEUR'S PIT (Ardent Lover of Flowers).—The amateur's pit, page 222, is, as you observe, one chiefly for first economy and continued utility. But, of course, like all mere pits, it does not afford the means for the proprietor working inside. Your proposed little house, 6½ feet high at back, and 4 feet in front, with a bed 3 feet wide, and a path 3 feet wide, will enable you to walk comfortably at the back; but if you can either raise your wall or sink the pit to make the back wall 7 feet in height, it will be still better. Your new house for propagating Cucumbers, &c., will stand at right angles with your present potting-shed and greenhouse. In your case we would place the flow-flue and return-flue beneath your bed, so as to have no obstruction in your path. If the wall of the flue next the path is made of brick-on-bed, you could continue the wall of your bed above it. For giving you moist as well as dry heat, see the plan suggested to Mr. Gooch, in making a tank between the two flues. You could do so easily by placing your two flues a little nearer each other. With such a contrivance you could always command dry and moist heat, and if the bottom of your bed were covered with slate, about 4 inches from the flue, you would always have plenty of bottom heat; and if you had drain-pipes set on end, one end open into the chamber, and the other end open above the soil or plunging material, and that furnished with a plug, you could let heat up as you liked. Even on the proposed arrangement of your section, without tank or anything of that kind, you could always obtain plenty of heat for the atmosphere of the house, by having a wooden brick made like a plug, every 4 feet, to place in the side wall of the chamber next the path, which you could pull out or put in at pleasure. Some mode of having a tank, however, would be useful. You could easily heat your two houses from the same shed, but we think you would do it most economically by two small fireplaces, as the greenhouse would need little fire except in frost. If your iron boiler is sufficient, there is no difficulty in joining the one-inch, which you now have, to three-inch pipes. The best way is by sockets to fit the three-inch pipes, and with such holes in the socket to receive the one-inch pipes. The simplest mode where there is little pressure, is to insert a plug of wood in the three-inch pipe, and take the one-inch pipe through it secured by white lead. This will not impede circulation. We agree with you, that hot water is the best mode of heating; but we contend that for heating a small place the flue is the more economical. We, therefore, have given such prominence to the pit of Mr. Atwood. The grafting will do very well if scion and stock are joined on one side. That is one of the quickest and best modes of grafting.

HOURS OF EMPLOYMENT (A Subscriber).—It is common when a man has a particular charge in a garden, when he has his Sunday out, to see that all is right before he goes, give suitable directions as to air, shade, &c., to the man left in charge, and see that all is right when he returns home. If he feels an interest in what is committed to his care, he will do all this without any specific agreement. Were he compelled to stay at home to see another man do the necessary work, he would have no rest or change on the Sunday. It is always best to have a clear understanding, and not to trust even to the use or custom. We have known cases of foremen who scarcely ever had a Sunday to themselves; but it told badly on all concerned.

FIRE HEATING (J. Prvor).—You surprise us by stating that in a house 20 feet by 12 feet, and heated by some 60 feet of flue, 11 inches deep, and 7 inches wide, you cannot have a higher temperature in a frosty night than 35, though high enough for a viney when you go to bed. If you consult a coal merchant he will tell you that some coals will cake even in a common fireplace, and go out if the poker is not used, and that others will fall as they burn, and need no touching until they are burned out. The latter would suit you best. With the good draught in your flue we would burn anything in it, and trouble ourselves very little about the kind of fuel. Such a length of flue ought to retain the heat a long time, even after the fire is out. Wet cinders and ashes should be used for banking up at night, but to prevent caking, and the fire going out, you must lessen or prevent air passing through the bars from the ash-pit door, as that is the chief cause of the fire going out and leaving a cake of unburned coal above; and if even that do not answer, you must widen your furnace 6 inches without using more bars for the freighting. Mr. Fish recollects a case in point. He, and another young man, had to attend to the fires of a stove in the evening, and the foreman attended to them at other times. During his comrade's week of firing there was always grumbling that the fires were out in the morning, though the heat was generally about the mark. He raked the bars before putting on the fuel for the night. Having made sure of the heat Mr. F. patted down the live fuel on the bars before putting on the fresh coal, with its covering of ash-ashes, and there was always plenty of fire in the morning, with a good chinker for the foreman to draw out. It was one of the cases in which doing the less was attended with the desired result. The putting the live fuel on the bars prevented the air passing through them, and combustion was much more slow. We think that such a mode, and keeping the ash-pit door close at night, will help to keep the fire in; but, even now, with 2 feet in depth of fuel, and all burned out, we can scarcely reconcile how the flue should become so cold during the night.

VINES FROM LAST AUTUMN'S CUTTINGS FRUITING (S.).—Vines, cuttings last autumn, rooted in January, and showing a good appearance of fruit now, are not at all common. We have seen and done such things as experiments, by taking long pieces of the severed stems, or shoots, of a Vine, and causing the lower part to root before the sap moved much in the part above ground; but the result in general was not equal by any means to that obtained from Vines treated in the usual way. Perhaps we do not quite understand your statement.

HARD WATER FOR PLANTS (W. H.).—The water of which you sent us a sample is hard, and probably from containing much lime and magnesia, kept suspended in it by carbonic acid gas. You can render it fit for watering conservatory plants by exposing it for a considerable time to sun and air, or adding to it a little soda, such as is used by washerwomen, or potash. By exposure to the atmosphere and heating it at the same time, the softening—that is, the depositing from it of the calcareous salts, would be hastened. You will see what Mr. Robson says to-day about water. We knew one very successful gardener who always mixed peat soil with the water he intended for his American and Heath plants, some hours before using it.

DOUBLE VIOLETS BECOMING SINGLE (Prosperal).—The Violets you planted last spring as double-flowered were certainly single at the time, though you did not know it. It is rare that double flowers become single, but it is not unusual for single to become double-flowering.

HEATING BY HOT AIR (A Constant Reader, Stockport).—Heated air, pure, free from smoke, will answer all the purposes you want, if the dryness is sufficiently neutralised. We believe you may carry out your plan if you superintend the working yourself, but we should be doubtful if the working were left to others. Besides, we much doubt if the air from the retort will heat 100 feet of such piping, and also doubt if it would be sufficient to heat the different houses. We also fear that unless you have a chamber round the retort, the sheet-iron pipes will last but a short time, and the having three of these pipes, one two-inch and one four-inch inside of an eight-inch pipe, makes it rather intricate. What is chiefly in your favour is the gradual rise in the 100 feet. We must say that we are doubtful of the successful heating of so many places by such means, one large place is so different.

WASHING VINES—PRUNING (B. & W.).—The best time for washing Vines is immediately after they are pruned, and the best time to do this is immediately the leaves turn yellow and fall. No better mode for doing this exists than to remove merely the loose bark with the fingers, and then scrub the stems with soap and water, and then when dry dash them all over with a paint made of water, sulphur, and clay. If the stems are well washed twice with soap and water, the clay darning may be dispensed with. Its chief use is to imprison any eggs of insects that may be left. As your Vines will now be budding, you must give up all idea of such washing for this season, and the best plan you can adopt is to mix a good deal of sulphur with the limewash you use for washing the walls, &c., of your greenhouse. As respects the Vine on which you have left two shoots, and one of which you would rather have cut back, do not think of cutting it now, and resorting to any mode to prevent its bleeding, but just wait until the buds have pushed to an inch or more in length, and then simply rub off with your fingers all the buds above that near the base which you wish to leave. The rubbing off will not be attended with bleeding. Cutting off the buds will cause bleeding.

CYCLAMENS NOT GROWING (R. F. Wheeler).—The pots of *C. comum* and *C. europaeum* should be plunged in ashes in a cold frame, and be kept there with the soil moist until the foliage decays. *C. persicum* should be kept in the greenhouse until June, and then be placed out of doors, returning it in-doors in September, by which time it will be pushing new growths, and may then be repotted. *C. comum* may be potted in the end of August or early in September, and *C. europaeum* will then be showing for bloom. It is hardy, and may be planted out on rockwork, covering the corn 3 or 4 inches with light friable soil. If it have a position shaded from the midday sun all the better. It is not unusual for Cyclamens to grow indifferently the first year, in consequence of their being deprived of their roots by taking them out of the ground, but they recover in a year or two.

ROSES FOR POT CULTURE IN GREENHOUSE (Idem).—Tea-scented—*Deviensis*, *Gloire de Dijon*, *Barillet Deschamps*, *Safrano*, and *Niphetos*. Noisette—*Miss Gray*, *Polonie Bourdin*, *Celine Forestier*, and *Triomphe de Rennes*. Bourbon—*Baron Guellé*, *Emotion*, *Réveil*, and *Souvenir de Malmaison*. China—*Madame Bréon*, *Triomphe de Gand*, *Archiduc Charles*, *Mrs. Bosanquet*, *Henri Cinq*, and *Indiélites de Lisette*.

GUANO FOR ROSES (F. J.).—Two applications of guano on the surface are sufficient for one year, if the plants have been well manured in winter; but your proposed weekly application of guano water is not too much, we have given it as often with good results.

PEGGING DOWN MOSS ROSES (Idem).—The shoots to be pegged down in place of the weak old shoots after they have flowered should, if they interfere with the effect, be pegged down loosely until the blooming is past; then, removing the old shoots, train in their place the new ones, but do not peg down closely until autumn.

AUCUBAS (J. H. Hutchinson).—There is no particular treatment required for a male Aucuba in bloom, further than applying its pollen to the female flowers. We are not aware of a cross between Aucuba japonica and himalaica. If in bloom at one time, that crossing could easily be tried.

NAMES OF PLANTS (J. Sude).—You were correctly informed. It is popularly known as the Artillery or Pistol plant, the anthers discharging their pollen in miniature explosions. Its botanical name is *Pilea muscosa*. (*John Baker*).—1, *Malvastrum capense*; 2, *Pilea muscosa*. (*Sophia*).—A form of *Asplenium adiantum nigrum*; but not the common English one. (*N. W.*).—1, *Aponogon distachyon*; 2, *Zenobia floribunda*; 3, *Cassandra calyculata*; 4, *Illicium floridanum*. (*C. Ford*).—1, *Hypnum triquetrum*; 2, *Dicranum scoparium*; 3, *Hypnum proliferum*; 4, *H. dendroides*. (*A Twelve-years Reader*).—1, *Pernettia mucronata*; 2, *Narcissus incomparabilis*. (*T. Shaw*).—The pieces of fronds sent are nearly all of them insufficient for naming, and we name only six at one time. 3, *Selaginella Martensii*; 8, *Onocidium japonicum*; 10, *Cyrtomium falcatum*; 11, *Nephrolepis exaltata*; 13, *Pteris cretica* (?).

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 14th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RAILWAY CHARGES FOR POULTRY.

We have at various times adverted to the great trouble and annoyance which exhibitors of poultry suffer from railway charges and railway neglect. It seems strange that any body of men should act so suicidal a part as do the directors of some lines in this country. Possibly all this may be done in ignorance, and the minor officials may be the chief parties to blame, but in any case we can very well understand why many exhibitors should determine on relinquishing a fancy that even if they are successful in prize-taking is often a positive loss to them. Moreover, it is not every individual who likes to have his digestion impeded by the presentation of a "railway bill," that on the face of it looks like an imposition.

We return to this subject again at the present time, because it would seem that the great body of exhibitors appear disposed at any rate to make their grievances known. An Englishman is said always to have some satisfaction in grumbling. Let us hope that some better result than grumbling will attend the present efforts. We are informed that the Poultry Club are intending to bring the difficulty before the various railway companies. Our columns of late have been much occupied with the subject, and, as many of our readers are aware, one of our contributors is endeavouring to find out by application to all the leading exhibitors their views on the subject, and we have already published three lists of exhibitors who are willing to sign a requisition to the various companies; we shall publish another shortly, and we apprehend that when the roll shall have been completed very few of the names of the leading poultry exhibitors will be absent, and, most probably, if absent it will be because the names are attached to the Poultry Club memorial. We cannot ourselves see any objection to an exhibitor signing both memorials; their object is the same, and there ought not to be any rivalry in the matter.

The railway companies themselves would appear to have no regulations at all to guide them. If they had, surely the curious charges complained of by Captain Heaton at the Poultry Club meeting and by Mr. Manning in our columns could hardly happen, and we sincerely trust that this effort may be the means of settling the question and fixing some regular but moderate rate of carriage that shall apply to all lines. There can be no question that these exhibitions very greatly increase the passenger traffic; as some return for this the companies may well afford to carry the specimens at a more reduced rate. We believe that this moderate rate, below the usual parcel rate, both ways, would meet the views of exhibitors more than a "free" return of the unsold poultry, many exhibitors believing that this means their being "free" to wait about at any station for an indefinite time. It is hardly possible that any change can be for the worse.

Our contributor "Y. B. A. Z." will soon have communicated with all the leading exhibitors; and we would remind those whom he may have overlooked, and those who have not yet replied to his communications that they can do so, as his address has been given in our columns.

THE DISQUALIFIED PEN AT WIGTON POULTRY SHOW.

No one regrets more than myself the necessity of your reporter's remarks on my Silver-spangled pen shown at Wigton, and reported in your last impression. I desire to say that I am as entirely ignorant of how the needle got into, or who put it into, the comb as those who saw it pulled out, and am prepared to make an affidavit to that effect. I never knew about the matter till I heard from a friend, who detailed the circumstances under which it was found; but this, even, not until I had found a "disqualified" card, and written to the Secretary to know what any pen of mine was disqualified for, being perfectly assured in my own mind that there was some mistake about the matter. I fetched the hen myself on Tuesday evening at seven o'clock from her run, and put her into a pen with the cock that was going with her, and I put them both into the hamper myself on Wednesday morning, and am positively certain that she was not trimmed in any way for the Show. Until I took her off her perch I did not know which I should send, and I only chose her as I thought she was in capital condition.

How long the needle had been in the comb to me is, therefore, a problem I am unable to solve. I am sorry to see your reporter's concluding remark, as it seems to hint that it had been put in to keep her comb straight. I have repeatedly been to see her since this, to me, unpleasant affair has happened, and I confess I cannot see that her comb droops on any side, and I scarcely think the Judge would deny that the pen was the best even after the needle was withdrawn. Do not misunderstand me: I do not complain of losing the prize under the circumstances, as, of course, the Judge and Committee would not be aware of my ignorance of the needle's presence. —A. K. Wood.

SOUTHERN POULTRY SHOWS.

I AM delighted to see that Mr. Lang, of Redlands, has fallen in so willingly with "WILTSHIRE RECTOR'S" proposal that a poultry show shall be held at Bristol, and has expressed his readiness "to work with all his heart in getting it up." If two or three can be found who will take the matter up with equal energy and determination, there is no reason why we should not have a first-rate show at Bristol. I for one, as a breeder of poultry, will give all my support, and doubtless numbers will come forward from the surrounding counties, to

say nothing of those at a distance, and encourage and help the undertaking. Mr. Lang asks breeders to propose a time which will least clash with other shows. I have been looking through last year's Numbers of "our Journal" and have come to the conclusion that in or about the first week in November would be a very suitable time for holding the Bristol Poultry Exhibition.—A. K. C.

DRAGON PIGEONS.

I AM pleased that my previous remarks upon Dragons and the little controversy between Mr. Percivall and myself have called forth the opinions of some fanciers and questions from others, and may be the means of bringing about a settlement of a subject which would appear to many of your readers of trifling moment, but which is of great importance to the fancy. For this reason I was, in the first instance, desirous of promoting a discussion upon the respective qualities of the two sorts of Dragons under notice, in order that the merits of each might be laid before those of your readers interested, and that these might judge for themselves whether or not it was folly for Mr. Percivall to exclaim "without reason or argument" against white-rumped Dragons, which have long been acknowledged, and ought to be admired, for the superior colour "they unquestionably possess" over those of Mr. Percivall's choice.

Again, Mr. Percivall comes forth without any argument, simply reiterating former declarations without one iota of evidence in support of his fancy, or a word to refute what I have said in favour of the birds he would discard. I do not wish Mr. Percivall to infer, as he does, that because the white-rumped birds form the great majority they should necessarily be the best; nor do I allow that because those of his fancy are so few that such should go in their favour. I ask any fancier to test for himself by placing one of each sort side by side, and I think I can safely say he will agree with my views. It does not require the educated eye of an artist to decide which is the better colour; for, as a rule, the superiority of the white-rumped birds is obvious to the casual observer. I do not feel satisfied to remain a silent reader of such prejudiced notions as those of Mr. Percivall, and by that silence sanction any crotchet or foible until such is acknowledged at the sacrifice of some of the best Dragons that can be bred. Blue Dragons are understood to be white-rumped, it is the exception to obtain them otherwise of a good blue colour, and, therefore, I think it unjustifiable for Mr. Percivall to persist in calling them worthless, and to wish to force his opinions on others, which, instead of making out the points of Dragons more clearly, would only cause the judging of them to be more complicated, and would necessarily lead to discussions as to whether they were white-rumped or not, as there are white-rumped ones, blue-rumped ones, and the various gradations of shades between the two; and as a matter of course, the nearer they approach Mr. Percivall's choice the more dowdy is their colour, and the less attractive and beautiful are they as aviary birds, and consequently it is an essential point against them.

Although Mr. Percivall does not flatter me in some of his observations, it serves his purpose in lieu of argument, and does not offend me. He has, however, given me credit for being wise in withholding my name; which, if that constitutes my wisdom, is a virtue I have no wish to retain. Having no desire to be an anonymous correspondent, I append my name and address to this letter, with the request that it may be published.

Mr. Percivall says, I may be a Dragon breeder, but certainly not a Dragon fancier. Not so certain, I say. The Pigeons I keep (solely for my own hobby or amusement), consist chiefly of Dragons, so Mr. Percivall may term me a breeder, fancier, or anything he likes. He has been bold enough to call me ignorant of what I have not attempted to describe—viz., the properties of a Dragon. As yet I have merely pointed out the difference between the birds under notice, although I flatter myself, my delineation of a good Dragon would be of service to Mr. Percivall, though I should feel it presumptuous in me to describe in your Journal what to many is so well understood. Mr. Percivall says he has for many years been a member of a society for the improvement of every kind of Pigeon. I cannot think the members of that society would say that white-rumped Dragons and Owls are worthless, and ought to be excluded from prizetaking. That birds which for years have so frequently occupied the most prominent places upon the prize lists of our exhibitions, and yet possessing such glaring defects, should have passed the notice of such a society, seems

strange. I know of one pair of white-rumped Dragons which have been shown at most of the exhibitions in England, and have been successful in taking upwards of fifteen prizes, so that they must have been closely scrutinised many times, and most likely have passed through the hands of those whose opinions are valued.

Mr. Percivall has thought proper to so far misconstrue my meaning relating to the black ticks, which I say so often appear upon the upper wing-coverts of the blue-rumped birds, as to call them "Chequers." I think I understand the meaning of chequers, and, had I thought proper to describe the small ticks in the exaggerated sense, I should have used the word Mr. Percivall suggests; but I think my meaning would be understood by those who have had experience with Blue Pigeons. The ticks, or specks of black I allude to, resemble those upon the tail feathers of Pile Game fowls, or the wings and tail of many of the Dun Antwerp Pigeons, and are not proper chequers, but graduated stippling of black from the top portion of the bar downwards; and again I say such are generally to be found upon blue-rumped Pigeons, and the darker the hue the plainer they are to be seen.

In your Number of March 20th a correspondent signing himself "AN AMATEUR" suggests the names of Mr. Hewitt and Mr. Esquilant, whose opinions, "he says," would carry great weight; for my part, I think the more opinions we obtain the better, the majority of which I think would endorse my views. Mr. Percivall selects from "AN AMATEUR'S" suggestion the name of Mr. Esquilant to whom he would refer. Why he omits that of Mr. Hewitt I can only surmise. In my opinion this last-named gentleman has shown himself of keen perception and good judgment when his decisions have come under my notice, and, therefore, I hope we may hear from each of the gentleman named.

I see Mr. Percivall noticed the remarks of "WILTSHIRE RECTOR," and in one particular, singular to say, I agree with Mr. Percivall, when he says that because white-rumped Dragons have been successful at Birmingham that that is no criterion. It does not necessarily follow on that account that they are perfect; but their beauty will recommend them, and they must be acknowledged, and when placed with others, and judged upon their merits, at the discretion of good judges, will be found, if not at the top always, still amongst the winners. As Mr. Percivall appears not to have noticed Mr. Brent's observations, I would recommend him to refer to the Number of March 20th, where that gentleman describes in a few pithy lines what is part and parcel of the true blue colour—viz., "the white rump." Mr. Brent has gained celebrity by his writings on Pigeons, and as I consider his opinion is of importance I take this opportunity of offering him my thanks.

As an ardent admirer of all kinds of Pigeons, and especially Dragons, I ask that those who read this controversy and are called upon to officiate as judges, may not be biased by what Mr. Percivall has said, but that they will exercise their own discretion in the awards they may make.—A DRAGON BREEDER (J. W. LUDLOW, 96, Edward Place, Fenchurch Lane, Birmingham).

THE SALISBURY MEETING OF THE PATH AND WEST OF ENGLAND SOCIETY.—It will be seen by an advertisement in another column that, in order to meet the convenience of numerous Exhibitors, the time for entering poultry has been extended to the 1st of May.

COOKING AN OLD HEN.—The *Massachusetts Ploughman* gives the following directions for "serving up an old hen so that she shall manifest, to mortal palate, all the delicacy and tenderness of youth:"—"Just cut her up into joints, taking care to go by the joints so that you do not get in any splinters of bones. Pick up all the bits of meat you have in the house, bones too if there is any meat on them, any odd pieces of ham or bacon, leg or shoulder of mutton, and a slice of salt pork, and cut a few slices of fat bacon and some bread. Take an earthen vessel with an earthen cover, with a bit of a hole in it, the cover, we mean, and put a layer of bread at the bottom of this vessel, then a layer of bacon, and then fill in with all the scraps and joints you happen to have—they must be sweet and clean of course—till the vessel is full. Then fill up the hollows and cracks with water, and tie down the lid. Put it at night in a very warm, not hot oven, and let it stay till morning. Take it out at your leisure and put it in a cool place, and when perfectly

cold, you will eat with gusto either for breakfast, luncheon, dinner, or supper, and you will find it not only tender, but juicy, and delicately flavoured, and highly nutritious. The water that

you put in will have turned into jelly, and the whole will cut like a red-veined marble. There is no way in the world you can work up an old fowl so economically or so splendidly.

BRINDLEY'S INCUBATOR.

This incubator is an oblong wooden case resting on four feet; the apparatus for thirty-six eggs being 2 feet long, 1 foot wide, and 7 inches deep. At the left-hand side, enclosed in wood, is a metal boiler, attached to which is metal tubing, which goes round inside the incubator, between, but not touching, glass. This space between the two glasses forms a chamber for the hot air. In a drawer at the bottom of the incubator the eggs are placed on a tray fitted with spiral springs covered with flannel, one for each egg, and by means of thumb-screws they are pressed so as to lightly touch the lower glass, which glass is to be kept at the heat of a hen's body. The heat is greatest at the top of the eggs. The necessary moisture for the eggs is drawn by the heat above, from water placed in the bottom of the drawer, which is metal. The thermometer is placed between the two glasses, and may be seen, as also may the eggs, without opening the drawer. The lamp is neatly enclosed directly under the boiler, and is easily removed for trimming, which is required twice a-day, and if the best colza oil is used there is little or no smell from it. There is not the slightest danger of any part of the woodwork taking fire.

When putting in the lamp-case, or removing it from under the boiler, do so quickly, otherwise the woodwork may scorch.

The loose flannel cover is for the glass outside, it keeps in much heat. Cover the bottom of the drawer with cold water, say half an inch deep, place the eggs, one on each spring, on the tray over this water, and, when the drawer is shut, screw it up so that the top of the eggs shall lightly touch the lower glass. The eggs do not require sprinkling, the necessary moisture for them is drawn by the heat above from the water below; as this water wastes it should be replenished. Keep the thermometer up to 110°; no harm will be done should it rise or fall a few degrees from this, but a temperature of from 105° to 110° should be maintained as far as possible. If too high, the ventilator opened and the loose flannel cover removed will soon lower it.

The eggs should not be put into the incubator until it has been working several hours, has acquired the proper heat, and

is in working order. Turn them once a-day. In four or five days it may be ascertained whether or not the eggs are birded by their being held before a candle in the dark; if alive, the veins may be seen moving. If it appears certain that they are not birded they should be replaced by others. Eggs may be added any time. The date of putting in should be pencilled on each egg. When the chicks burst the eggs the thumb-screws must be lowered to give them plenty of room, and they should be kept in the incubator a few hours; they require nothing but the requisite warmth for the first twenty-four hours after hatching.

Should the temperature of the incubator by accident fall very low or rise too high, it may not follow that the vitality of the eggs is thereby destroyed; get the heat right again as quickly as possible, and keep the incubator working on. The top may be screwed off when it is required to clean between the glasses.

BEE'S RECOLLECTION.

THE following particulars show the recollection which bees retain of locality after nearly six weeks' absence. On May 12th, 1863, I had two swarms within an hour of one another, both of which settled on a Deodar tree on my lawn, a favourite place, by-the-by, for settling, for two out of three of my swarms. It is my almost invariable rule never to remove swarms to their destined locality until the evening of the day of swarming. This was done, but the next day began with a drenching rain with high and cold winds, such as was prevalent during that unfortunate summer. Some of the bees coming out and, of course, going to the Deodar, were at once chilled with the cold, the hives not being there. This was too much for my philosophy, and I accordingly replaced the swarms where they had pitched. The next day was as bad, and the next not much better, the bees going out a little during gleams of sunshine in the afternoon, when I was absent in the city. The result was, that I was afterwards afraid to remove them to their intended stands, and resolved when the weather settled to send them to a friend's house a mile and a half away, to cause them during a five or six weeks' absence to forget their domicile, and then place them where I originally intended, without causing that puzzling and often loss of bees, which result from removals to short distances. This was done, and though this is not the point of my letter, I may add that the next day, notwithstanding they were a mile and a half removed, I saw ten

or twelve bees hovering round and sticking to the old places showing that at this distance in fine weather bees will find their way back.

In about six weeks' time I had them back again, and then, feeling sure that they must have forgotten where the swarms had pitched, I placed them on the site originally intended. To my utter astonishment, the next morning I saw fifteen or twenty bees again flying round the old places on the Deodar where the swarms had originally settled, this being about 50 feet from where the hives were now located. These bees continued at this off and on all day, and, I believe, never went again to their proper place.

All swarming was long since over with me, so it could not have been from any other hives, and all my bees were at that time busily engaged with the Lime blossoms, so abundant in Blackheath Park and the vicinity.

Having been a bee-keeper for more than a quarter of a century, I like to remember these and other traits of my special favourites, and could give you, also, other proofs of their peculiarities from my own personal experience which might interest you. I am rather an enthusiast upon the subject, but can bear a joke consequent thereon, notwithstanding that I am—A BLACKHEATH'AN.

[We shall be glad to hear again from you.]

IMPROVED FRAME HIVE.

Tim suggestion in page 265 respecting bars with projecting ends, is, doubtless, a good one for those who are commencing with bar-and-frame hives; but the alteration would be found exceedingly troublesome to make by those who have already adopted another pattern. Moreover, the projection cannot be used in a bee-house, when it is necessary for the front of the hive to fit closely.

Having experienced the difficulty referred to in handling heavy frames, I have used a couple of square hooks—if the bull may be allowed—that is, the hook simply bent at a right angle, and not returned. This I often find useful when the frames are tightly fastened in, especially in a house where the front of the hive is not easy to reach. Of course, the frame is first loosened, and the hook inserted sideways between the comb is merely used for lifting out.—F. H. WEST.

OUR LETTER BOX.

EGGS NOT HATCHING (S. T. H.).—We fully sympathise with you, after paying 28s. for nineteen eggs, and these having to travel only about thirty miles, you were entitled to expect more than two chickens. At the same time you have no claim against the vendor. He is an honorable man, but, if he had no contrary reason, we should have expected he would have sent you a dozen as a compensation.

LACING ON WINGS OF SPANGLED HAMBURGS (J. P. F.).—Lacing has been decried because it is difficult to obtain. It should belong to Spangled fowls, and always did. Look at the wings of Silver-spangled Polands. It is effectual in those classes. Every breeder of Spangled birds knows how difficult it is to breed colour into one part of the body and out of the other. It is difficult to obtain the spangled breast and barred wing with a clear tail. We can recollect the time when all had barred wings, but they had not clear tails. Lacing is a serious difficulty, but it is anything rather than a defect.

Poultry Failures (M. C.).—You do well in all things except chickens, and there is no reason why they should fail. We have a dozen Brahma hens with chickens, and they have never done so well as this year. Our loss is not 5 per cent. We are great admirers of the Brahmas for their sitting properties and their maternal virtues. Your feeding is good, but if you can find any miller who will grind your oats into fine flour, without taking anything from it in the shape of bran, you will find it very profitable, more so than whole oats. Indian corn is good for a change, but it does not make good chicken meal. You do not seem to require any other knowledge, as success is a fair test, and you are successful. Let your sitting hens have plenty of room. When they break their eggs it is generally because they are cramped for room; and when they crush the chickens it is because their ribs are too small. We have ours 24 inches each way.

Ducks Laying Soft Eggs (A. C.).—Aylesbury Ducks, like hens, will sometimes lay soft eggs. This arises from the lack of that which forms the shell. In Ducks the care for soft eggs is generally to feed for a few days on oats put in some vessel, with gravel and a sod of growing grass. Cochins often lay very early after hatching their chickens, but seldom at the end of a month. The hen in question must supply the breakfast eggs. The chickens are too young to be left, especially at this season of the year.

BUTTERING EGGS FOR EXPORT (Mrs. Talbot).—We think it would spoil eggs for hatching if they were buttered. That is a process used for keeping them fresh for the table, but it is an unnatural process for hatching, and we follow Nature in these things as nearly as we can. We think eggs might go safely to South America packed in a basket with dry moss, each egg being rolled in it. They should be kept in a cabin, or some place where there is air. Eggs will keep a long time and yet hatch—certainly a month.

DEFICIENCY OF COCKS (S. P.).—You have too many hens for two cocks. You should have at least four. Last month, and earlier in the year, five for your fifty hens would not be too many. Sometimes cocks are reconciled by being placed in pens where they can see each other through wire netting or other open work without being able to get at each other. Our own idea is to let them have their quarrel out, care being taken that they shall not fight to the death. We always adopt that plan. If you object to that, do as follows:—Take a long rod 8 or 9 or more feet long; to the end of it tie an empty bag, such as an old pillow-case. When the cocks are sparring, and intent upon it, they will allow you easily to come within reach. Measure your distance, and buffet them right and left with the bag. They will be astonished, and will desist for a minute or two. They will then begin again. Repeat the operation, and after two or three applications a cure will be effected. If the covered runs are to protect the chickens during the night, use them by all means; but if they are for the day, discontinue them. Let the hen be under her rip, but let the chickens have free course through the bars. Choose a dry (if possible), and a somewhat sheltered spot, and if the rats are troublesome place a board in front at night; but you must recollect that chickens want their liberty at daybreak.

GIBBINESS IN FOWLS (B. G. H.).—Your chicken running sideways and turning its head has the "gids," and will never grow up to be a good one. We advise you to kill it, and thus save the food it will eat without making any return. It is the sort of chicken kindly little girls take to as a pet, because it is so funny. If your Cochins were Dorkings or Hamburgs we should say they had rump; but as Cochins are not subject to it we believe it is only a cold, which may be removed by feeding on bread and ale for a day or two.

SPANISH FOWLS (J. Mechanic).—You will find plenty of Spanish fowls and eggs advertised in our columns. The Spanish fowls as originally imported had white faces. We have known one cock sold for £80, and two pens containing each a cock and two hens sold at Liverpool for £200. Your garden is large enough for a Spanish run. Eggs hatch well after travelling.

GOOSE LAYING MANY EGGS (B. B.).—If the Goose in question is a Toulouse Goose she will not sit; if she is not, she will. One of our Toulouse Geese last year laid forty-five eggs.

ERECTING A HEN-HOUSE (A Reader).—You may make an excellent house with the space you mention—viz., 6 feet in depth and 18 feet in length. Brickwork is not necessary; boarding will do perfectly well. Let the house be at least 6 feet high; if higher so much the better. Have a wooden, slate, or tile roof. As the length is three times the depth, and as light is very essential, you must have an opening or window at the end, near to the roof—one that can be opened or shut as the season may require. The door should be at one end, the perches within 2 feet of the other, running across the house; the laying-boxes facing the door. The water should not be in the roosting-house. Recollect, the larger the run you can allow your fowls the better they will do, and nothing is so good as grass and shrubs. The flooring of the house should be gravel on earth, the latter well rammed down and the former loose on the surface. The mortar and rubbish may form the foundation of the floor, but there should also be a heap of it in the run. They dust in it, and the hens find the material for the eggshells among it. You will not have room to rear chickens in the smaller space; they should be in the larger place where you propose allowing the fowls a run once a week. Wire netting will make all secure, and the covering at top will depend on the breed you keep. We do not recommend Dorkings for confined spaces. The best breeds are Cochins and Brahmas. These are not wanderers, and will remain contented without any covering at top. Another advantage of those breeds is, that their chickens are hardy and easy to rear. We should advise the purchase of useful birds of either of these breeds, and that you buy some good eggs to put under the hens as fast as they become broody.

AYLESBURY WITH CAROLINA DUCKS (An Inquirer).—There would be no risk of any evil consequences if Carolina and Aylesbury Ducks ran together, but we are bound to tell you it would be incongruous. Aylesbury Ducks are large, heavy, and common-looking; foul feeders, and thriving best in a yard where they forage in search of food. Carolina Ducks do well in a small pond in a flower garden, where they can always be seen and fed, becoming tame pets. The peculiarity of the latter is, they will not make a nest, but will lay their eggs about, taking no note of them unless they are provided with a proper place for nesting, which should be exactly like a small dog-kennel fastened above the water to a pole in the middle of the pond, and having a plank to reach the water. Small ridges of wood must be nailed across this plank to give the Ducks foothold. The back of this kennel should be lower than the front, and there should be a head to prevent eggs from rolling out. Carolina Ducks are very hardy, as much so as common Wild Ducks. We believe their price varies between 50s. and 70s. per pair. We do not think the eggs are to be had.

GOLDEN PHEASANTS (Idem).—They want no particular management. They will thrive and lay well in a small place. Their food is barley, with a little bread at times to keep them tame, and to attach them to their feeder. There is risk in allowing them to run wild in a garden. Golden Pheasants cost about 60s. per pair. Their eggs are to be purchased, but we do not know the price.

RUSSIAN BANTAMS WITH CREVE COEURS (J. F.).—We do not know the size of the Russian Bantams. If they are larger than the Sebrights, which weigh 17 ozs., and if the Creve Coeurs are small, there is risk. As a rule we do not consider Bantams dangerous among fowls of a large breed.

SILVER HAMBURG EGGS UNFERTILE (Done For).—We believe your suspicion to be correct, and age is the cause. You can easily ascertain by examining some of the eggs that have been under the hen. If they are not impregnated they will be apparently as fresh as when they were laid.

COCHINS-CHINAS NOT LAYING (A. F. W.).—The continual wet is bad for the condition of poultry, and that which takes from their condition interferes with their laying. Feed on barley and good oatmeal, with Indian corn only for a change. We think with finer weather you will have more eggs. We do not much wonder why the hens should lay about. If they eat their eggs, you must buy some hard composition ones about, they will peck at them till they are tired and will give up the habit.

TICKS ON CHICKENS (Idem).—Our experience is that chickens have done well this year. We have not before heard of any ticks about poultry. Wood ashes mixed with black sulphur, nineteen parts of one to one of the other, and small dust of any kind laid about the haunts of chickens, are considered effectual in removing parasites of any kind, as the chickens dust freely in them, and thereby get rid of the parasites. If by "warmly" you mean that you employ artificial heat, discontinue it. It never does any good in the long run.

MANAGING LIGURIAN BEES (A. B. C.).—You must either super your Ligurians or let them swarm. If you decide on the former plan the super should be put on towards the end of this month; if the latter, you had better get a couple of hives made at once, after the pattern of the frame hives you already possess. The probability is that your black colony is defunct, and the Ligurians have been plundered.

PREVENTING SWARMS ASCENDING (A New Beginner).—We cannot tell you how entirely to prevent the loss of natural swarms. All that can be said is, that with trees and shrubs in the immediate neighbourhood of the apiary they generally cluster in them and submit to be hived. A strict watch should, however, be kept during the swarming season, and we should certainly give chase with the view of recovering an errant swarm, instead of merely watching its departure in solemn silence.

PROSPEROUS BEES (B.).—You can do nothing more to advance the prosperity of your bees. Even feeding may be an evil, if carried to excess, since if all the cells were choked with food the queen could lay no eggs in them, and breeding would be checked, if not entirely stopped. Your bees will fill their hive with comb as soon as they are numerous enough, and then the super may be put on. A bee which is licked by others has probably been soiled with honey or food.

WHICH IS THE BEST BEE HIVE? (Prospera).—All depends on the degree of skill possessed by the apiarist. For those who never advance beyond the wisdom of their forefathers, the old-fashioned bell-shaped straw hive is the best and most convenient, whilst those who go a step farther and put on an occasional super will be contented with the same kind of hive improved by one or more prices in the top; but for the true bee-master frame hives are far superior to all others.

WEEKLY CALENDAR.

Day of Month	Day of Week	APRIL 24—30, 1866.	Average Temperature near London.			Rain in last 39 days.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock after Sun.	Day of Year.

29	SUN	4TH SUNDAY AFTER EASTER.	58.4	37.7	48.0	13	38	4	17	7	1	7	26	4	○	2	46	119
30	M	Abelia floribunda.	61.4	39.5	50.5	16	36	4	18	7	1	8	3	5	15	2	54	120

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 59.3°; and its night temperature 37.5°. The greatest heat was 81°, on the 28th, 1840; and the lowest cold 18°, on the 29th, 1861. The greatest fall of rain was 1.40 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

SOME HINTS AS TO THE ARRANGEMENT OF FLOWER-BEDS AND BORDERS.

HINTS on the above subject are desirable, now that the season for bedding-out is rapidly approaching, and accordingly I offer a few, in the hope that they may

prove useful to the readers of the Journal.

Any of the following arrangements will look well if the beds are surrounded by grass.

No. 1. Centre, Verbena Velvet Cushion, about 2 feet wide; next, a band of Geranium Manglesii, 2 feet wide, with the flowers kept on; this Geranium, however, will require to be kept pegged, so that it may well cover the space of ground allotted to it; between it and the grass put an edging, 1 foot wide, of Viola cornuta. This would make a magnificent bed.

No. 2. Centre, Iresine Herbstii; 2nd row, Viola cornuta; 3rd row, Cerastium tomentosum. The centre in this arrangement should be 2 or 3 feet wide, and each of the other rows about 15 or 16 inches in width.

No. 3. Centre, Purple King Verbena; 2nd row, Geranium Bijou, with the flowers picked off; 3rd row, Lobelia speciosa; 4th row, Arabis lucida variegata.

No. 4. Centre, Geranium Flower of the Day, with the flowers left on; this should be 3 feet wide. Next to it plant 2 feet of Verbena General Lee, then 18 inches of Viola cornuta, finishing off next the grass with a margin, a foot wide, of Geranium Golden Fleece.

No. 5. Centre, Centaurea candidissima; 2nd row, Coleus Verschaffelti; 3rd row, Cerastium Biebersteini.

No. 6. Centre, Mrs. Pollock Geranium; 2nd row, Lobelia speciosa; 3rd row, Cerastium tomentosum. This should be kept pinched-in very closely, so as to form a very close and compact edging.

No. 7. Centre, Amaranthus melancholicus ruber, 3 or 4 feet wide; next to this a row of Golden Fleece or Cloth of Gold Geranium, 2 feet 6 inches wide; then a band of Lobelia speciosa, 18 inches wide; finishing off with a nine-inch margin of Variegated Alyssum.

No. 8. Centre, Verbena Ariosto Improved; 2nd row, Geranium Christine; 3rd row, Verbena Ruby King.

No. 9. Verbena General Grant. This is a very large pink flower, of fine shape and substance; next row, Viola cornuta. This was one of the finest beds at Oulton last summer.

No. 10. Centre, Geranium Cybister; 2nd row, Verbena Mrs. Holford, or Snowflake; 3rd row, Amaranthus melancholicus ruber.

No. 11. Centre, Calceolaria Brown Prince of Orange.

This should be planted pretty closely together, some small pieces of wood being stuck around each plant to prevent its being broken by the wind; if nicely put in the sticks will support the plants all through the summer, and the foliage will soon hide them. A good margin, 2 feet wide, of Mimulus cupreus would look well, and if the bed is situated in a shady part of the garden it will not easily be surpassed for beauty all through the summer months.

No. 12. Centre, Calceolaria Victor Emmanuel; 2nd row, Geranium Flower of the Day; 3rd row, Verbena Claret Queen; 4th row, Lobelia Paxtoniana.

No. 13. Centre, Geranium Christine; 2nd row, Geranium Spread Eagle; 3rd row, Geranium Queen of Queens.

No. 14. Centre, Geranium Bijou; 2nd row, Purple King; 3rd row, Golden Fleece.

No. 15. Centre, large bed, twelve large plants of Canna discolor, covering a space of 4 or 5 feet; next a band of Cineraria maritima, 3 feet wide; then a two-foot band of Iresine Herbstii; finishing off with a margin, 1 foot wide, of Viola cornuta.

No. 16. Large bed. Centre, seven good plants of Humea elegans; these occupy 6 feet, let the tallest and best plant be put in the centre, and plant the other six in a circle round it; then plant Verbena Maonetti Princess Victoria between the Humeas, and allow it to cover the whole surface of the bed between them, allowing it to extend about 9 inches or a foot outside of the circle formed by their stems. Next put a two-feet-six-inch band of the true Lobelia speciosa, dotting this band alternately with two rows of Cloth of Gold or Golden Fleece Geranium about 18 inches apart. These, however, should be very nicely-shaped little plants, and must not be allowed to grow too large; they can be easily kept within their proper bounds by frequently pinching them in. Finish with a good margin of Cerastium tomentosum, a foot wide, next the grass. This would be a magnificent bed.

No. 17. If it is desirable to have a pair of large circular beds similar to No. 16, the centre of 17 should be planted the same; but the two-feet-six-inch margin, instead of being planted with Lobelia speciosa, may be planted with Cerastium, and dotted with neat little plants of Iresine Herbstii or Coleus Verschaffelti, using Lobelia speciosa for the outer foot margin.

No. 18. If Nos. 16 and 17 form a sort of triangle with No. 18, the latter should be planted as follows:—Use three good Humeas for the centre, fill up the space between them with Verbena Velvet Cushion, let 6 feet of the centre be covered with Verbena Velvet Cushion, using a row of Fuchsia Meteor outside the Humeas. These should be kept nicely pinched in, so that they may form handsome-shaped plants, and they must be planted alternately. Next plant 2 feet 6 inches of Geranium Manglesii, allowing the flowers to remain on, and finishing off with a foot margin of Viola cornuta. The effect of these three beds planted and situated as above described would be very fine.

No. 19. A bed planted with Lobelia speciosa, and dotted with nice little plants of Fuchsia Pillar of Gold, would look well. This bed may be improved by edging it with Lobelia Snowflake.

No. 20. Centre, Stella Geranium; 2nd row, Calceolaria Aurea floribunda, with an edging of Lobelia speciosa, would look well.

No. 21. An entire bed of Mrs. Pollock Geranium, with a simple edging of Viola cornuta, would be very effective.

No. 22. A bed of Lobelia speciosa, margined with Lonicera aureo-reticulata, would also look well.

No. 23. A mixed bed of Verbenas planted indiscriminately is always very effective.

No. 24. Mignonette and Intermediate Stocks, with a margin of Jenny Lind Stock next the grass, are always looked upon with great interest by almost every one having a taste for simplicity and sweetness.

No. 25. A bed filled with some of the choice hybrid Pyrethrums, Dianthus, Fancies, Mignonette, and Carnations, is always very interesting and sweet.

No. 26. Nothing is more beautiful nor more highly appreciated than a good bed of Clove Carnations.

No. 27. Tropæolum Elegans makes a good bed edged with Mentha variegata.

28. Verbena Scarlet Cushion. This will produce one of the most dazzling effects that can be imagined. For small beds or front rows in a ribbon-border this is the finest Verbena ever brought before the public, offering the greatest depth of colour and substance of flower. No one would think that a plant of so dwarf a habit could produce such wonderful trusses of bloom in such profusion and of such substance. It is one of my latest productions, and belongs to a race of hybrid Verbenas originated by me, and which, I believe, are destined to supersede the greater portion of Verbenas at present such favourites for bedding-purposes.—J. WILLS.

(To be continued.)

CULTURE OF VINES IN POTS.

(Continued from page 275.)

FRUITING.—To have fruit ripe in March and April, forcing should be commenced in the middle of October; to have it in April and May, in the middle of November; to have it in May and June, in the middle of December; to furnish ripe fruit in June and July the Vines should be started in January, and in February for the same in July and August. The Vines not started until March, and only assisted by a little fire heat in damp, cold periods, will afford fruit in August and September; whilst for fruit to ripen in the latter month and to hang till Christmas, the Vines should not have any forcing, but be allowed to come on in a cool house, employing a little fire heat in autumn only, to dispel damp and assist ripening. For fruiting at the first two periods the canes should have the wood ripe—brown and hard—by the beginning of August, and the leaves should be off, or be in a fit state to be pulled off, by the end of the month. The best Vines for early crops are those two years from the eye. For forcing in and after December, those from eyes of the current or previous year will do if of sufficient strength, the eyes plump and round, and the wood brown and hard.

PRUNING.—Considering that the best eyes are invariably situated at the upper part of the cane, and that the eyes for a foot or more at bottom do not generally show fruit, it is well not to reduce the canes too much. I allow from a foot to 18 inches of the lower part of the cane to go for nothing, leaving 5 or 6 feet of sound, well-ripened, plump-eyed cane above that, and thus reduce the canes to 7 feet in length, a few inches more or less. On that length of cane there will be a sufficient number of good eyes to give as much fruit as the Vines will carry. If the Vines are to be trained to the roof, the length of cane required to reach the roof must be counted as non-producing, and there should then be a length of bearing cane which need not exceed 7 feet, nor be less than 5 feet. The cane should be reduced to the length required for early forcing as soon after the leaves become ripe as practicable, for though it may do to pull off the leaves when they become yellow, to prune, and to force the Vines at once, still they will not be so liable to bleed, and they will do better if allowed a rest. It is not desirable to commence forcing the Vines until they have had at least six weeks' rest; thus, for starting in October the canes should be denuded of leaves and pruned in the end of August; for starting in November, by the end of September; and for starting in December, in the end of October or early in November. For starting in January prune in the end of November or early in December, and for starting in February prune about the middle

of December, and Vines for later crops by the beginning of January.

The laterals should have been removed when the vigour of the Vine has been controlled by lessening the supply of water, and when the ripening of the wood warrants it. In no case ought they to be left on until the time of pruning, for their removal at an earlier period is essential to the ripening of the cane, and left on until the time of pruning, their removal then is only making cuts that may bleed, and this close to every eye along the cane. Bleeding may not induce a bad breaking of the eyes, but it does materially weaken the strength of the shoots.

Though I would always have the canes trained 16 inches from the glass, it is not always practicable nor desirable; but I am convinced that Vines never do so well as when trained to the roof with the shoots producing fruit carried to the right and left of the rod; their ends, or where the fruit is situated, being 3 inches nearer the glass than the rod. Nevertheless, the canes are sometimes, I might say commonly, coiled round stakes from three to five in number, put in round the pot, and these may be 2½ or 3 feet out of the soil, and be so far thrust in as to be firm. The stakes should therefore be 3½ or 4 feet in length. The canes are coiled round the outside of the stakes and fastened thereto, care being taken not to twist or wrench them, otherwise they will assuredly bleed. The only merit this system may have, at least the only one I ever observed, is that the eyes break well from bottom to top. The best bunches are those at the upper part of the coil, these receiving the most direct light. The canes for coiling should not be less than 7 feet, nor more than 9 feet in length. Sometimes, but rarely, the canes are trained upright, and the side shoots tied to side stakes put in for the purpose. The canes in this system are never suffered to become so long as those trained to a roof, but are kept stopped to 3 or 5 feet, depending on the laterals for the strength of the rod. Beyond removing the laterals, the pruning is confined to cutting away the stoppings at the upper part down to a good eye.

The Vines being pruned and in their fruiting-pots, the drainage should be examined, and if not good it must be rectified. If not in their fruiting-pots the Vines should be put into them at once, loosening the roots a little around the outside of the ball, but not to any great extent. If not potted, remove as much of the surface soil as can be done without injuring the roots, and replace it with fresh. I find turves, cut 2 inches thick, and laid up in alternate layers with sheep's droppings, an inch thick between each layer of turves, form an excellent top-dressing after having lain twelve months and been turned over twice. The compost previously advised for the last shift will answer admirably, adding to it one-sixth its bulk of bone-dust. As abundance of water will be required, the drainage must be good. After the Vines have been pruned the soil should be kept dry, but not dust dry, and as cool as possible—merely protected from frost. A few degrees of frost will do the canes no harm; but the pots must be protected by a covering of hay or dry litter in frosty weather.

FORCING.—If the Vines have been fresh potted it is essential for their well-doing that they have the benefit of a mild hot-bed of well-fermented dung or leaves, in which the pots can be plunged to the rim. Its temperature should not exceed 70°, nor be less than 65°. Where a bed of leaves or well-fermented dung can be made, whether the Vines have been repotted or not, I would strongly advise the pots being plunged in it at least two-thirds their depth for a fortnight or three weeks, by which time the heat will have declined, but not until the roots have been excited and become active. With a good root-action there will be no difficulty in making the eyes break freely and strongly in the dull autumn and winter months. The pots may remain plunged in the bed of fermenting materials, and the roots striking into it will contribute to the vigour of the Vines. If the bed sink considerably at the end of a fortnight, it may be raised by the addition of fresh fermenting materials, so as to bring the pots to the required distance from the glass. If rooting into the bed is not desired, the pots must be removed before that takes place, and the heat of the bed should be so reduced as to be equal to the temperature of the house. The top heat, whilst the pots are plunged in the hotbed, should for a fortnight not exceed 40° from fire heat. This fortnight is over and above that usually allowed.

The house for the reception of the Vines should be thoroughly cleaned, the glass washed with water, and the woodwork with softsoap and water, taking care to keep it off the glass, the walls whitewashed, and the flues swept and put in good order. A good limewashing of the flues is excellent for stopping up

cracks. The pots having been placed in the position they are destined to occupy, each cane should be tied to the rafter at the point immediately over the pot, and there only, the cane being allowed to fall from that point, the end on a level with the rim of the pot. If it will not do this of its own accord, or through its weight, it must be fastened thus low by a stone at the end. This will cause the eyes at the bottom of the cane to break well, raising or lowering the cane as the eyes seem disposed to break at the lower or upper part. The main point is to secure their breaking equally well from top to bottom. If trained to the rafter at once the canes will only break half a dozen eyes at the upper part, and the highest of these will be the strongest, and they will be so, even after measures have been taken to prevent it. When the eyes have broken well the rod should be fastened to the rafter.

TEMPERATURE.—To start Vines in autumn a higher temperature is required than in spring. For the first fortnight the temperature should, therefore, be 45° to begin with, increasing to 50° at night by the end of that time, and in another fortnight it should be gradually increased to 55° at night. By the end of the third fortnight the thermometer should read 60° from fire heat at night, and this should be the maximum night temperature until the Vines are in flower, when it should be increased to 65° at night. The night temperatures are to be counted from the readings of the thermometer at daybreak, when the minimum is attained. From that time the temperature should increase gradually until 1 p.m., and it should then be 5° higher than the night temperature on dull days, 10° on those which are cloudy with clear intervals, and from 15° to 20° on bright days. After the fruit is set the night temperature may be 65°, and not less than 60°, though it is well to have it 5° lower, rather than 5° higher, than the necessary night temperature. An excess of 5° in the night temperature will do more harm than 5° too little. The day temperature after the leaves are fully formed may be allowed to rise to 85° or 90° on clear days, these extremes of temperature being from sun, and not promoted by increased fire heat. When the Grapes change colour the night temperature may fall 5°, or be 60°; they will colour much better in that than in a higher temperature. The Grapes fully ripe, a lower degree of heat will keep them more fresh and brisk in flavour; the temperature may, therefore, be 55°, or as low as 50° by night.

ATMOSPHERIC MOISTURE.—At the shutting-up of the house on starting the Vines, they should be syringed morning and evening with soft or rain water always of the temperature of the house, until they are in leaf, when, if the weather be cold and dull, they should not be syringed more than once a-day, and that in the morning; but if the day be clear so that air can be admitted, then they should be syringed in the morning by 9 a.m. (I am speaking of winter, from November to March), and again in the afternoon at the time of closing the house. In addition to syringing the Vines, the floors, walls, and those parts of the flues which are not very hot, should be kept moist by wetting them in the morning, at noon, and in the evening, and this must be continued until the Grapes change colour. If the day be dull, then a thorough wetting of the paths, walls, and other available surfaces will be ample provision for keeping the air moist; and this should be done in the morning or early in the afternoon. It will be well on such days to dispense with the syringe, but whenever the weather is mild and the days clear, then the syringe must be used twice a-day until the Vines are in flower, then discontinue its use as regards the Vines, but still keep the house moist by wetting the floors, walls, &c. When the flowering is over syringe twice daily—in the morning and at the time of shutting up the house, or very soon afterwards. The water should be directed at the foliage, so as to strike upon it like a brisk shower of rain, and it will fall upon the bunches like a refreshing shower. It must not be directed against the bunches so as to strike them on the under side, or upwards, for that injures the bloom, but coming down upon them it does not. The scorching of Vine leaves is often attributed to syringing the foliage, but I have practised this for many years, using clear rain water. I have no attacks of thrips or red spider, and I can recommend gently syringing the foliage at all times, except when the Vines are in flower, and after the Grapes have changed colour for ripening. Heavy syringings seldom given, like heavy rains, are not desirable; they break and injure the foliage, and it is better not to syringe at all than do this.

After the Grapes change colour leave off the syringing, but keep the floors and walls moist so that the berries may swell well, diminishing the supply of moisture, however, so as to

discontinue it altogether by the time the Grapes are ripe, after which keep the atmosphere dry, no water being allowable if the Grapes are expected to hang.

WATERING.—At starting the soil should be no more than moist, and clear water will do until the eyes have broken, and for a time until the Vines are in leaf, then more copious supplies should be given—thorough wettings, and not dribbles. Weak liquid manure may be applied once a-week. No water should be afforded until the soil has become so dry as to render a thorough watering necessary—one that will reach the bottom of the pots; but it will not do to wait until the leaves flag. When the Vines are in full leaf they will require thorough waterings daily; vigorous Vines once, twice, or thrice, according to the weather. Liquid manure may be applied twice or thrice a-week in not too strong but yet in good doses, for though strong ones are injurious, very weak and frequent applications do not seem to do much good. A most excellent liquid manure for pot Vines is made by dissolving a peck of sheep's-dung in thirty gallons of water; let it stand half a-day, then stir it up well, and after it has been allowed to stand half a day more, stir well up again, and then strain through a coarse bag or cloth. One pound and a half of Peruvian guano to thirty gallons of water, and treated in the same manner, will form an excellent liquid manure. A good watering with either once or twice a-week will be found more efficient than frequent waterings with weaker solutions.

Copious waterings are to be continued until the fruit is ripe, when water is only to be given in sufficient quantity to maintain the foliage and fruit fresh. All water used should be heated to the mean temperature of the place in which the Vines are grown—for instance, if the temperature by day be 75°, and that of the night be 60°, the water should have a temperature of 67° or 68°.—G. ABBEY.

(To be continued.)

THE MANETTI STOCK FOR ROSES.

In compliance with the wishes of "COUNTRY CURATE" (page 253), I will join the mite of my contribution with those of Mr. Kent, and others. I am amused with his description of his shallow soil. He describes it as not being more than from 2½ to 3 feet deep. I have no such depth here. At my future residence at Okeford Fitzpaine, I shall have a strong rich soil 3 or 4 feet deep. I dare say I shall have to learn and unlearn much. I should say from his description of the dying of his fruit trees, that it is occasioned by iron in the land, the very land for the British Queen Strawberry. I recommend him to keep the perpendicular roots cut back, and to encourage the horizontal roots. As his soil is strong, it will cause strong succulent Rose wood on the Manetti stock, and he will do well to root-prune, or remove the Roses annually, and prune the roots tolerably severely. Perhaps I shall have to do the same. If he can grow Broccoli and Cabbages to perfection, he ought to be able to grow Roses on either the Manetti or the Briar.

As regards budding the Manetti stock, he may bud it as early, or late, as the stock will run. Early in the year the bud need not be fully developed; but late in the year, both for Briar and Manetti stocks, I think a full, ripe bud would be more likely to stand. In the sultry season much depends on the quickness with which the operation is performed, and also on the "tie." A bud will fail from opposite causes—from being tied too tightly, or not tightly enough to exclude the air. I do not practise raising Manetti stocks, nor do I bud many. I put the novelties on Briars, because it is more agreeable.

I believe that Manetti cuttings should be about 10 inches long, with a leaf at the top, and that one-half should be hurried, and the ground trodden tightly. September is the best time for striking cuttings, because the earth is then hot, and the air is cold. I saw in September, 1860, at Mr. Keynes's, a quarter of Manetti for budding, consisting of, probably, 10,000 stocks. Not one in a hundred had failed. They were planted in September, 1859, and when I saw them they were strong trees, nearly up to my chest, with wood as strong as one of my fingers. As "COUNTRY CURATE'S" land is strong, and probably the Shropshire air in winter is cold, he would do well to scatter leaves amidst the slips, or horse-litter, or straw, all of which are excellent "frigi domos." I know two good propagators of Manetti Roses. One plants the slips in a shallow trench, and the other on the flat. They both bud from 2 to 4 inches above the radius of the roots. I recommend "COUNTRY CURATE," if he bud in either fashion, and wish to protect his buds, to put

on leaves or litter before he returns the earth against the stock and bud. When he cuts away the stock, and the shoot grows, he may then close the soil carefully against the shoot, covering the point of union at least 2 inches. Nine inches from slip to slip, and 2 feet between the rows, are sufficient room for simple propagation. The closer the plants are together the better they grow in hot, dry weather. In the autumn they can be removed.

As regards the severity of the Manetti stock, I believe that to be a fact. Some years back Mr. Cranston told me, "I have 20,000 Manetti Roses. I want 100,000 stocks. If I had them budded I could sell them." In these parts Manetti Roses have entirely superseded the Briar Roses. I hear from Mr. Taylor, of Fenote, Yorkshire, who lives in the fine vale of Mowbray, that the Manetti Roses beat the Briar Roses. Of course, I know that the Briar fails oftentimes from persons being ignorant of its requirements, and that in first-rate Briar land. The same may be said of Manetti Rose failures. I believe, at present, there are very few real rosarians. The fact is, they are general florists, and take care of nothing. Their floral establishment is a "curiosity shop." For strong, deep, mottous, well-drained clays, and rich deep loams, the Briar is still a first-rate stock. For careless and ignorant people, in any kind of land, the Manetti Roses are the best, for if they are free growers they will make a better fight against ignorance, neglect, and the various shocks of time.

I have no prejudices on any subject. My future garden is suited to Briar Roses, and I have just planted 120 stocks. In autumn my Manetti Roses, Briar Roses, and Roses on their own roots, will be moved into that land, and, of course, I do not expect my experience to remain exactly the same; but, whatever the alteration may be, I shall make it public.

I would advise all the readers of this Journal to keep their stocks well watered before budding, if the weather is hot. Then the hotter the weather is (tie a leaf over the bud) the quicker is the union. Early in the morning, or in the evening, in hot weather, is the best time. I sometimes after budding pour a little water over the bud. I budded my Briars this season in intense heat, and hardly any failed. I think people cut the slits for the reception of the bud unnecessarily long. Half an inch is long enough.—W. F. RADCLIFFE, *Tarrant Rushton*.

THE COILING OF VINES AGAIN.

I HAVE been interested with the recent discussions on the coiling of Vines. When two such mighty gladiators as Mr. Rivers and Mr. Thomson cross swords it must be on some important matter, and some important facts must be elicited in their discussions. One scarcely knows which the more to admire, the home thrust of the one or the skilful parry of the other. There is a possibility of both being right, and I as an on-looker think so. In offering an opinion, however, I know how dangerous it is for pignies to interfere in the battles of cranes for fear of utter annihilation, or at least a billip of chastisement; and a young practitioner of a score years' standing ought to think before indulging an opinion, lest a ponderous piece of experience of four score, with its accumulated inertia, should send him with one bound back to begin a second novitiate; but fools sometimes step in where angels fear to tread, and I do so on the strength of one piece of experience which I have to produce, since the opinions of others seem to be invited.

Last year, in February, I had ten excellent pot Vines left of different sorts, with canes 6 or 7 feet long, in 10-inch pots, with fine plump eyes on the 3 feet at top. I determined to have them fruited to stand on the table; so the pots were plunged in a spent bark-bed near the glass, the rims just covered, and about 3 feet of the stems laid down on the surface of the tan, and just covered over for the sole purpose of hiding that part of the stem and pot. The top 3 feet was passed through the hole of a six-inch pot, which was made to stand on the surface of the tan, the pot filled with soil, a stake with cross pieces applied to the Vine to keep it upright, and so the Vines were started. Throughout the summer many were cheated into the idea that the Vines were growing entirely in the six-inch pots until undeceived. The Vines broke well, and showed well for fruit, and all went well until about the second swelling, when away went the Vines into strong growth, the berries ceased to swell satisfactorily, and they were long in ripening; in fact, they became useless for our purpose, they continued to grow so determinately and so gross. They were, however, cut over at the surface of the bed, and removed with

the small pots. The 10-inch pots, with the 3 feet of layered stem, were left in the bed until this spring, when, on removing them, the cause of the gross growth of last year, though well known, was doubly apparent. The whole length of the stems was found to be densely fringed with roots striking horizontally into the old tan, and when drawn out resembled immense centipedes; the old roots in the pots did not seem to have made any further progress, and really seemed as if they had been dormant. I think when these new roots from the layered stem came into action in their unlimited pasturage, that then the Vines started into woody growth, and the old and fruit-giving roots were superseded, and the successful finishing of the fruit completely frustrated.

Now, although the layering of the Vine in the tan may at first sight seem analogous to the coiling of the Vine in a pot, still the result might have been different. Had the Vines been merely coiled round the surface of the large pot they would have rooted centipede fashion, but would have only had the original potful of soil to root and feed in; still I should be shy to allow the new roots to interfere with the action of the old in perfecting the crop of fruit. This is, however, the point where it will be interesting to know the result of Mr. Rivers's experiment.

In my case the Vines rooted freely all along the stem, but then they were only just covered with the tan, and I am satisfied that they would not have done so if covered 8 or 10 inches. I think there is no doubt but the contact with the influence of the atmosphere was the cause of their rooting so profusely. It is often seen in striking Roses or Geraniums, or even Willows, that the part in the soil may die or damp off, but a whorl of roots is produced at the surface, and this invariably happens when the soil is too wet or close, so as to exclude the air; heat has, apparently, not by any means so much to do with the matter.

I am interested in this discussion, as, at the opening of it, I had just laid down some three-year-old Vines across an inside border from back to front to fill up some vacancies, but merely pegging them on the surface. They are making roots freely, and the Vines are growing strong; I fear I shall not have well-finished fruit from them, but that I anticipate.—A PROVINCIAL.

ROYAL HORTICULTURAL SOCIETY.

APRIL 17TH.

FLORAL COMMITTEE.—Mr. Murrell, gardener to J. C. Pickersgill, Esq., exhibited two plants of *Kamperferia ovalifolia* noticed last week; and seedlings of *Myosotis* from Messrs. Hance & Schmitt were again placed before the Committee, but not in a condition to form any idea of their merits. Mr. Hopwood, Cheltenham, sent two seedling *Cinerarias*—a white one, named *Virgin Queen*, and *Chancellor*, a rosy purple. Mr. Williams, Finchley, exhibited two neatly-arranged baskets containing cut flowers of two seedling *Tropæolums*. Attraction, if of good and dwarf habit, is a very promising flower, deep yellow with scarlet markings at the base of the petals; *Beauty*, the other was a pale yellow variety. A special certificate was awarded for the simple, yet pretty, arrangement of the flowers.

Messrs. Veitch sent a very interesting collection of plants containing Orchids, Azaleas, Rhododendrons, Anthuriums, &c., which received a special certificate. The Orchids were particularly fine. Among them were some very superb specimens of *Trichoplia suavis*, *T. anavis* *superba*, and *T. crispata*. The Committee recommended these Orchids as worthy of the Lindley Medal, which was granted them by the Council. In the collection of plants we noticed a very beautiful hardy Japanese shrub, *Raphiolepis ovata*. It had been before the Committee when first introduced, and received a label of commendation. Now that it has been better grown it proves itself to be a first-class plant; it has not been seen before in such perfection. The white spikes of its sweetly-scented flowers make it very attractive; the foliage is dark green. This is a plant which must find its way into every garden as soon as it is known. Mr. Bull sent several interesting plants. Among them were *Aspidistra Sieboldii*, a hardy variegated-foliaged plant, the same as *Aspidistra lurida variegata*; *Camellia tricolor imbricata plena*, a small, pretty, striped flower; *Nidularia Pinellii*, very similar to other *Nidularias*; *Pitcairnia tabulariformis*; and *Psychotria macrocephala*. The last-named plant was much admired. Some doubt, however, existed as to its having received any previous award. Should it not have done so, it will be duly noticed at the next meeting. It is a very beautiful plant, sending up large masses of pure white flowers from amidst its large green leaves. Mr. Salter, Hammersmith, sent a very beautiful seedling *Camellia*, *Princess Mary*, flower bright red, excellent form, and fine dark foliage. For this a first-class certificate was awarded. Mr. J. Cox, gardener to W. Wells, Esq., Redleaf, brought cut specimens of *Rhododendron Aucklandi* and *R. campylocarpum*, one of the Sikkim varieties, an early-flowering kind, with pale lilac flowers. A special certificate was awarded it.

Mr. Edmonds, gardener to the Dowager Duchess of Sutherland,

Chiswick House, brought some magnificent cut flowers of *Camellia reticulata* and other varieties for distribution. A special certificate was awarded them. Mr. Green, gardener to W. W. Saunders, Esq., exhibited several curious plants. Among them were *Scuticaria Steelii*, a pretty Orchid with very long, narrow, lush-like foliage; *Amorphophallus papillosus*, and *Peperomia* species, of which the name at present is not known. This received a first-class certificate. Mr. Pilcher, gardener to S. Rucker, Esq., brought cut specimens of *Odontoglossum Pescatorei*, most superb; also, *Schomburgkia tibicinis*, and beautiful blooms of *Cattleya Skinneri*. A special certificate was awarded for this exhibition. Several specimens were sent from the Society's gardens. Two large plants of the Persian Lilac, in full flower, received a special certificate. Mr. Barron brought two large boxes of cut *Camellia* flowers, from plants growing out of doors under a north wall at the Chiswick Gardens. The flowers were particularly perfect and well-coloured, and proved very acceptable to the ladies after the meeting was over.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. On this occasion Mr. R. Ruffett, gardener to Viscountess Palmerston, Brockett Hall, received a first-class certificate for three dishes of Apples in a most excellent state of preservation. They consisted of Mickleham Pearmain, Seartel Nonpareil, large and fine, and Cox's Orange Pippin. They had been kept on open wooden trellises in a low, lean-to, slate-roofed house, rather damp, through which a current of air was constantly passing from ventilating-openings to an air-shaft in the roof. The seedling Apple raised by Mr. Balchin, of Dorking, and which received a first-class certificate at the last meeting, was again produced, and it was named by the Committee Balchin's Pearmain. In addition to the above, a dish of *Æsopus Spitzberg* Apple came from T. Hall Bailey, Esq., Leigh; and from G. Blenkins, Esq., Warwick Square, the fruit sold in Covent Garden under the name of "Japoniens." They were stated to be the produce of the *Zizyphus vulgaris*, cultivated in the south of France, and other parts on the shores of the Mediterranean, from the fruit of which the jujubes of the shops are made. It was, therefore, concluded that the fruit sold in the market as being from China, did not come from there, and had nothing to do with Japan.

FORTNIGHTLY MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the awards of the Committees had been announced, the Rev. M. J. Berkeley said, as Mr. Bateman was present, he would leave to him that which constituted so interesting a part of the display—the Orchids. With reference to *Aspidistra Sieboldii*, it was doubtful whether the variegation would remain permanent, as green leaves were occasionally thrown up. The genus to which it belonged was a curious one, with peculiar flowers, having a stigma very closely resembling a common Mushroom. Of *Crianna capense*, it was remarked that it might prove useful to hybridise with, on account of the fragrance of its flowers; but *Crianna* were a class of plants not popular with cultivators. *Nidularia Pinellii* closely allied to the Pine Apple, and *Pitcairnia tubulariformis*, both of which were exhibited by Mr. Bull, having been mentioned, *Psychotria macrocephala*, also from the same, came under notice, and Mr. Berkeley said he did not think any *Psychotria* had flowers like the plant exhibited, for they bore more resemblance to those of a *Rudgea*. The genus *Psychotria* was closely allied to *Coffea*. One species (*P. emetica*) was used for the same purpose as *ipecaeanha*, to which, however, it was inferior, and another, *P. noxia*, was employed in Brazil as a poison for mice and rats. At the previous meeting *Rhododendron Griffithii* had been exhibited, and it was then stated that there existed a close resemblance between it and *R. Aucklandii*. There was this difference, however, as would be seen by the flower of *Aucklandii* before the meeting, that *Griffithii* had a more tubular flower than *Aucklandii*, the limb not being so much expanded. Attention was next directed to the *Camellia* blooms from Mr. Edmonds, and the Society's gardens at Chiswick. The latter were the produce of three plants of an old variety called the Middlemiss Red, which, being very large, were some years ago, at Mr. Fortune's suggestion, planted on the north side of a wall, that position being chosen because *Camellias*, notwithstanding their hardness, frequently suffer from the direct rays of the sun. This proceeding was attended with such success, that the plants now present a magnificent appearance. The male catkins of *Wellingtonia gigantea* from Mr. Cox, of Redleaf, were then adverted to, and Mr. Berkeley reminded his hearers that a few weeks ago he had brought with him specimens from the Marquis of Huntly's, and which were believed to have been the first male catkins of the *Wellingtonia* seen in England. Mr. Berkeley next called attention to *Peziza lanuginosa*, a species never recorded as British till recently. It had, however, been discovered by Mrs. Sumner, and he had called it *Smanceriana*; but Mr. Edmonds had brought a basket of it to the meeting, it being found by hundreds under Cedar trees in the grounds at Chiswick House, where it grows like *Truffles* under the ground, and bursts forth with great force. Mention had been made at the previous meeting of an experiment being made to grow *Truffles*, and another had been set on foot with a view to the cultivation of other esculent fungi. In connection with this subject it was remarked that spawn of a Mushroom said to be much superior to the common kind, had been imported from Swan River, and the attempt had been made to cultivate it by Mr. Henderson, gardener to Lord Fitzwilliam, but in consequence of the long voyage the spawn had lost its vegetative power. Endeavours, how-

ever, would be made to procure what appeared to be so valuable a variety. Although it was generally supposed that in Mushroom beds but one species was to be found, this was not the case, for not merely were there varieties of that species, but species belonging to other genera. It was often the case, that where Mushrooms succeeded at first, they afterwards failed, through being attacked by a parasite analogous to the caterpillar fungus of New Zealand. The production of Mushrooms from spawn had been used as an argument in favour of spontaneous generation, but like all others in support of that theory, it fell to the ground; for though spawn bricks were prepared from the droppings of the horse and other animals, according to various receipts, yet the seeds, to speak familiarly, of the Mushroom, had passed through the body of the animal. The municipal authorities of Paris only allowed three kinds of fungi to be sold in the markets of Paris—viz., the *Agarius campestris*, *Truffles*, and the Morel; but many erroneous notions prevail as to the number of edible fungi, for, after all, the poisonous species are few in comparison to those which are not so. Hence it is desirable that information should be more generally diffused as to the latter, especially as from their containing nitrogen they are valuable in a nutritive point of view. As an instance of their utility in this respect, Mr. Berkeley cited the case of a schoolmaster who almost supported his family on fungi in the autumn months, and that of a gentleman who, whilst in a wild mountainous district in South Wales, had for some time nearly subsisted on the *Boleti* which he there found. Once or twice, however, he was nearly poisoned, and it should, therefore, be borne in mind that the unwholesome species of *Boletus* turn blue when wounded. Of the Mushrooms sold in Covent Garden comparatively few belonged to *Agarius campestris*, nearly all being the Horse Mushroom (*Agarius arvensis*). In the use of fungi however, it was necessary to use some discretion, and as an example of the evil results which might arise from their incautious use, a case was mentioned in which Dr. Badham had sent *Agarius muscarius*, a poisonous species, to a gentleman for the purpose of making a decoction to destroy flies, and the gentleman being from home, the ladies, thinking that Dr. Badham would never have sent what was not perfectly wholesome, had some for breakfast. Now this *Agarius* was in the north of Asia mixed with Cranberry leaves, in order to produce an intoxicating drink, and with the ladies it produced a similar result. *Agarius ostreatus* found on the bark of dead trees, and bearing considerable resemblance to an oyster, was then pointed out as being wholesome; and *A. muscarius*, one of the most common species, Mr. Berkeley said, he had been informed by Dr. Hogg, was very desirable and excellent. For those who were interested in edible fungi, he would mention two or three books which they might consult. First there was Dr. Badham's "Esculent Fungi," which was rather expensive; there was a little work by Mr. Cooke; and "A Selection of the Edible Funguses of Great Britain," edited by Dr. Hogg and Mr. Johnson, and illustrated by Mr. W. G. Smith. Mr. Smith, he might add, had recently been commissioned to make a series of drawings of edible fungi for the Science and Art Department at South Kensington.

Mr. Bateman having been called upon by the Chairman, apologised for the absence of *Dendrobium MacCarthiae*, or the Ruddy-mouth flower of Ceylon, which, through some mischance, had not arrived, but he hoped to bring it before the next meeting. In respect to *Epidendrum crubescens*, which was perhaps the most beautiful of all Orchids, he had also sustained a disappointment. Happily there were in the room a few Orchids on which he would offer some observations, and the first to which he would direct attention was *Schomburgkia tibicinis*. This had received its specific name not in consequence of the flowers being trumpet-shaped, but in allusion to the peculiar form of the pseudo-bulbs, which are large, long, and hollow, exactly like a cow's horn, and used by boys in Honduras to make a similar discordant sound to that obtained from the latter. The pseudo-bulbs, however, in the plant's native country were not so easily taken possession of as one would imagine, for they were frequently tenanted by very ants. *Cattleya Skinneri*, and the *Trichopilia* from Messrs. Veitch, were then noticed; and in connection with the latter, Mr. Bateman remarked that a Lindley medal had been awarded to Messrs. Veitch on that day, and that they had also carried off the challenge medal which he himself had offered for the exhibitor gaining the greatest number of marks for Orchids in two consecutive years. A magnificent spike of *Odontoglossum Pescatorei* was the next subject which occupied attention. This, it was stated, had been grown by Mr. Rucker on the cool system of culture, which was eulogised as being the means, in the case of certain Orchids, of producing visions of beauty such as had never been expected on the old system. The difference in the appearance of Orchids as flowered soon after their introduction and in subsequent years was then touched upon, and a drawing of *Odontoglossum Alexandrae* from a living plant in flower, but the number of blossoms taken from dried specimens, was offered as an illustration of what that species is likely to prove. The distinction between it and *O. Pescatorei* was also stated to be that the one produced its flowers in racemes, whilst the other—*Pescatorei*, produced them in branching panicles. *Dendrobium Heyneanum* was then adverted to, as likely in a year or two to present quite a different appearance. Mr. Bateman next directed attention to two species of *Callixene* or *Luzuriaga*, which would give a charm to the coolest greenhouse. They were first noticed about ten years ago in the catalogue of the then firm of Messrs. Standish and Noble, and were stated to be hardy. Having received them along with some *Rhododendrons*, they were planted out of doors, but, not

withstanding the mildness of the winter, they were barely alive in spring. Finding it hopeless to attempt to cultivate them out of doors, they were planted in the bed of a conservatory. *Callixene polyphylla* immediately began to grow, forming quite a dense carpet over the ground, but no flowers were produced. Eventually, however, it laid hold of a *Nepal Berberis*, and no sooner did it touch the stem than it began to clamber up it, and eventually flowers like *Daisies*, but more delicate, were produced. The other species was more slender than the first named. *Callixene polyphylla* was sent at the time of its introduction to the Royal Botanic Gardens, Kew, and was figured in the "Botanical Magazine" for 1860, where it is stated that it comes from the extreme south of Chili, "belongs to the same natural family as our well-known *Lily of the Valley*, and is generally seen running over the trunks of trees near the ground, enveloping them with bright green Box-like leaves, glaucous beneath, and gracefully drooping flowers of the same pure white as the *Lily of the Valley*, but much larger." Mr. Bateman in concluding expressed a hope that the plant would be distributed among the members of the Society.

Mr. Wilson Saunders remarked that the plant was not lost in the country, as he had it in flower, but he did not find it so ready to run up—a circumstance probably due to the roots being confined in a pot.

Fifteen new Fellows were elected; and the Royal Institution of Cornwall, and the Malmsbury Floral and Horticultural Society, were admitted into union.

WEEKLY SHOW, April 21st.—For a collection of twelve miscellaneous plants there were two competitors—Mr. Young, of Ughate, and Mr. Bartlett, of Hammersmith; but the plants in both were of such an inferior description that each received a third prize. In the collections of six miscellaneous plants, Mr. Young, and Mr. Beasley of Twyford Abbey, Acton, received equal second prizes, and Mr. Bartlett a third prize. For a collection of twelve cut blooms of *Camellias*, Mr. Trussler, gardener to J. Kay, Esq., of Hoddesden, received the first prize, and Mr. Young a second. For six miscellaneous plants, Messrs. Cutbush received an extra first prize for very handsome specimens for their size, and also an extra second for a collection of eight small *Azaleas*. For a collection of *Cinerarias* and *Calceolarias*, Mr. Beech, gardener to W. Rogers, Esq., Redhill, received a first-class certificate, and Mr. Young a similar award for a collection of *Tulips*.

For the best collection of fruit, Mr. Miller, of Combe Abbey, exhibited bunches of *Lady Downe's Grape* in fine condition, and of excellent flavour. They had been preserved on the Vine since they were ripe in September, and were allowed to hang until the sap began to rise, and actually burst the berries by the force of its ascent. He also exhibited new bunches of *Foster's White Seedling*, which were good at this early season. Mr. Miller received the first prize. The second was awarded to Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, for a punnet of very good early Black *Hamburgh Grapes* and one of *Kyren's Seedling Strawberry*.

ROYAL BOTANIC SOCIETY'S THIRD SPRING SHOW.—APRIL 21.

THROUGH the subjects exhibited on this occasion were not very numerous, *Roses* and *Pelargoniums*, which were the principal features, gave the exhibition tent a gay appearance. Of pot *Roses* there was a fine bank contributed by Mr. Turner, of Slough, and Messrs. Paul and Son. The former took the first prize for nine with fine examples of *Charles Lawson*, *Beauty of Waltham*, *Juno*, *Souvenir d'un Ami*, *Victor Verdier*, *Maréchal Vaillant*, *John Hopper*, *Celine Forestier*, and *Le Rhone*. From Messrs. Paul & Son, who were second, came *President*, *Madame A. de Rongemont*, *Prince Camille de Rohan*, *Maréchal Vaillant*, *Anna Alexiév*, *Souvenir d'un Ami*, *Le Rhone*, *Niphotos*, and *John Hopper*. Collections in fine bloom were likewise furnished by the same exhibitors and by Messrs. Lane, of Berkhamstead, comprising among other varieties plants in excellent bloom of *Madame William Paul*, *Duchesse de Caylus*, *Dr. Andry*, *Vainqueur de Goliath*, *Jean Rosenkrantz*, *Baron Adolphe de Rothschild*, *Madame Victor Verdier*, *John Hopper*, *Souvenir d'un Ami*, &c. The only *Roses* shown in the Amateurs' class were half a dozen from Mr. James, gardener to W. F. Watson, Esq., Isleworth. For three new *Roses* of 1864, 5, and 6, Mr. Turner was first with *Leopold Hausberg*, a fine deep rose, *Marguerite de St. Amand*, peach, and *Madame Derieux Donville*; and Messrs. Paul & Son second with *King's Acre*, *Flora*, and *Madame Moran*. Mr. Turner also exhibited *Prince of Wales*, a promising rosy crimson seedling; and Messrs. Paul and Son half a dozen boxes of fine cut blooms.

In *Pelargoniums*, six plants in excellent bloom from Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, took the first prize. The varieties were *Vestal*, *Madame Rivet*, *Pleum*, *Beadsman*, *Roseum*, and *Monte Christo*. Mr. Clarke, Whitton, who was second, had *Roseum*, *James Lodge*, *Venus*, *Alma*, and *Bracelet*, several of which were in good bloom. Of *Calceolarias*, Mr. James had likewise an excellent exhibition, the plants, seedlings of his own, being fine, both as regards the size, colour, and profusion of the bloom. *Lord Derby*, large, with rosy salmon markings on a buff ground; and *Beauty*, dark crimson, marked with yellow, were two of the best. *Cinerarias* were exhibited by Mr. James and Mr. Lacey, gardener to C. S. Mortimore, Esq., Carshalton, the former also contributing a stand of

twenty-four cut blooms of *Pansies*, and a dozen plants in pots. A stand of cut *Pansy* blooms was also shown by Mr. Hooper, Bath.

Anriolicas came from Mr. Turner, Slough; Mr. James, Mr. Paine, Kentish Town, and Mr. J. Butcher, Camberwell. Those from Mr. Turner were by far the finest, and consisted of *Moore's Violet*, very beautiful, *Grimes' Privet*, *Heady's Splendour*, *Traill's General*, *Neill*, *Summerscales' Catherine*, and *Netherwood's Othello*. Mr. James, who was first in the Amateurs' Class, had *Lovely Ann*, *No plus Ultra*, *Prince Albert*, *Conqueror of Enrop*, *Meteor*, *Flag*, and *Mrs. Smith*. Mr. Turner likewise exhibited twelve varieties of *Alpines*, several of which were very pretty; and Mr. Wiggins, twenty-five *Polyanthus*.

Of other subjects, Messrs. Lane & Son sent a collection of *Rhododendrons* in pots ranging from 6 to 9 inches in diameter; the plants were very dwarf with large heads, consisting of seven or eight fine trusses of bloom. These had an excellent effect. From Mr. Wiggins came forcing *Pelargonium Porporeum*, soft bright rose, with a light eye, and a dark blotch in the upper petal; also *Dendrobium cucullatum giganteum*, with a large cream-coloured lip, and long narrow petals and sepals of a delicate pink. The habit was pendulous. Messrs. E. G. Henderson again exhibited their white-keeled variety of *Cianthus Dampieri* and silver-variegated *Japanese Ivy*; also *Rhododendron Veitchi* and *Lilium tenuifolium*, of slender growth, and bearing orange scarlet blossoms. Miscellaneous collections of flowering and fine-leaved plants from Mr. Williams and Mr. Wheeler were similar in character to those exhibited at the previous Show. Ornamental-leaved *Begonias* were also shown by Mr. Wheeler.

FRUIT CULTURE.

To commence with Mr. Robson's experience as stated at page 269 in paragraph 1, it seems to me so confined. He has "had occasionally" to manage trees worked on some kind of *Paradise stock*, has neither denoted the sort, the soil, or the climate, the number of years the trees had been planted, or whether growing in grass land or a garden. I beg his pardon—He names "a friend of mine," with trees growing in an extensive orchard, among which were some on *Paradise stocks* "no longer healthy." Most undoubtedly this is true. The *Paradise* is a surface-rooting stock, and requires the cultivation of a garden. An orchard under grass would destroy trees grafted on that stock. This is so evident, that one cannot help feeling surprised at a sound experienced man like Mr. Robson omitting to observe it. The great advantage of employing the *Paradise stock* is this—it is incalculable—that such kinds as are at all inclined to canker (and in some deep soils it will affect trees), can be lifted and replanted, so that their roots are brought to the surface and canker arrested. I have done this so often, and have seen the unvarying effect, that to me it seems childish to mention it.

In paragraph 2 Mr. Robson talks of "filling the basket." Now, this is all very well with market-gardening; but the amateur, if I may judge by my own feelings, would rather see a peck of fine Apples ripening on his bush or pyramid secure from "stormy winds," than five bushels of inferior fruit on a standard exposed to them. But even in market-gardening there is no comparison with regard to the profit of growing Apples in an orchard and of cultivating them in a well-managed fruit garden. Any clever industrious man, who would plant an acre of ground with dwarf Apple trees on good *Paradise stocks* 3 feet apart, or 4840 trees per acre, and graft them with his own hands, and afterwards attend to them by summer-pruning, would reap a harvest such as no orchardist ever experienced. He must be a man not moving in the groove of old ideas, but "upwards and onwards." The difficulty he would have to meet would be that of procuring land, for at the end of seven years half the number of his trees would have to be removed, and an additional acre of land provided for their reception. Unlike Mr. Robson, I do not go to my neighbours to look and learn; but I first try if an idea is feasible, and then make it known to the world.

In paragraph 3, the notice of the stain in the *Laburnum* in the "Horticultural Transactions" was relative to the discovery by Mons. Adam, a nurseryman at Paris. I am trusting to memory, but at that time the purple *Laburnum* was a recent introduction, and led to much controversy. I have seen hundreds of the shields of the buds of the purple *Cytisus* full of life, the bud being dead, but I have never witnessed the like stain; and what has struck me as a curious fact, the *Cytisus elongatus purpureus*, a variety between *C. purpureus* and *C. elongatus*, very distinct and beautiful, never has stained the stock, although it is here budded on the purple *Laburnum*; and in 1864, after the winter which killed the buds but left the shields alive, not a stock was stained, although I quite expected to find them so stained. Some of your readers who

have leisure will perhaps look into the Horticultural Society's "Transactions," and put this matter right. I had no thought of being discourteous; but one of my age has seen so much of culture, that a firm expression often comes to hand when writers on horticulture give expression to opinions not founded on experience, the parent of truth.

Paragraph 4. I did mistake Mr. Robson with respect to the Quince tree. In this county it is a tree of humble growth, and owing to its dwarf habit it dwarfs the Pear, making it a garden tree rather than an orchard tree. Mr. Robson gives qualified praise to Pear trees on the Quince stock. I pray his pardon when I say that his experience in this matter seems to me very limited. If he had studied the culture of Pears on the Quince he would see how much there is in the future. In my opinion—and it is not given without much thought and practical experience—we are mere tyros in Pear culture, and twenty years hence our present imperfect management will be looked at with contempt and surprise. It is only within a few years that some new kinds of Pears, which were probably raised from fruit gathered from Pears grafted on the Quince, have shown a tendency to a perfect union with the stock—more so than any of the old varieties (this is a most interesting question for the physiologist); and in my opinion, owing to this, their growth is vigorous almost beyond belief, often putting forth shoots from the bud thick as a stout finger, and from 6 to 7 feet in height in one season. This is the advantage to be seized upon by the observant cultivator; for if these varieties are grafted with kinds dilicult of culture when grafted directly on the Quince stock, a healthy, vigorous, prolific habit is given to the graft. I may instance that most excellent but shy-bearing sort, the Gansel's Bergamot. I have known a tree of this sort double-grafted—i. e., grafted on a stock as described above, to bear three dozen of fruit the third year after being grafted; and I am fully convinced that it might be made a profitable article of culture by that simple operation. Moreover, by cultivating it as a bush or pyramid, so as to be within reach of the cultivator, its blossoms may be fertilised with the pollen of some common free-bearing sort, as its blossoms are often deficient in pollen: hence its tendency to be what is called a shy bearer. I may also point out here the great advantage of careful culture as exemplified in this variety. I have known a Gansel's Bergamot Pear tree grafted on the Pear stock to be ten years before it produced blossoms. There are other sorts of Pears equally benefited by this method of culture—one in particular, which I feel would be a fortune to a poor man. Some three years since I took occasion to regraft some large vigorous trees of the Vicar of Winkfield Pear on the Quince. Last year they bore a fine crop of the largest and most beautiful Pears I ever saw. They were sent to market in December, and made 10s. and 11s. per half sieve, or a guinea a-bushel, my salesman at the same time sending me word that I had kept them a fortnight too long, or they would have made considerably more. Now, any clever persevering cultivator might plant 700 trees of this sort, 4 feet apart, on a rood of ground, keep them pruned in as close pyramids, and make a little fortune. Like all good things, some trouble must be taken to arrive at a good result. Quince stocks must be planted, budded with the proper sort, and then double-grafted. This will be the work of three seasons, and seasons well employed.

As to the prize fruit Mr. Robson writes about, they are all "leather and prunella," being gathered from wall trees, the fruit carefully thinned for the purpose. I wish to see good Pears in the gardens of the people as well as in those of the great and grand, and I shall continue to try and teach how they may be cultivated.

In paragraph 7, Mr. Robson is just as erroneous in his calculations as was a "Kentish Fruit Grower" last year, in a contemporary. If he wished to buy ten thousand Spruce Firs, would he think of buying them at the retail price, 3d. each, charged in small nurseries when a few are wanted?—as much trouble to take up as they are worth. I think not; he would buy them wholesale at 30s. or 40s. per 1000. This is not, however, germane to the matter. A clever fruit-grower would plant stocks, and graft or bud them himself. The expense of preparing one acre of land for planting Quince stocks is not heavy, it should not be trenched but forked over with Parkes' steel forks. (I am presuming that no careful man would have anything to do with inferior land.) This could be done at 6d. per rod, the price here. The annual forking and hoeing would be something under £4 per annum; and judging from the rapid way in which thousands of trees here have their

summer pruning attended to, an active man fond of the thing would do two thousand trees in "over hours" in the summer. I have always in my mind a cultivator with an active mind and active hands. I may add, that I have proved all that I assert.

In paragraph 8 Mr. Robson is frolicsome, something after the manner of Dr. Johnson when he trifled with Boswell. I mentioned the facility with which Pear trees in gardens could be protected, I did not allude to market-garden trees. The remainder of this paragraph is an attempt at wit, and I am sorry to say there is a something deserving an ugly name. I can forgive the attempt at wit, but not the other thing. Mr. Robson says, "Rather than told us he had several thousands of such trees to sell." Is this to be found in the article I have written? Have I mentioned having "several thousands of fruit trees for sale?" Oh, fie! Mr. Robson.

Paragraph 9 is about as weak an illustration of what may be done in fruit-culture for market as it is possible to imagine. The case as stated by Mr. Robson is quite unsatisfactory; not a word is said about the soil, the climate, or the kinds of fruit planted. One is able to understand that Mr. Robson never saw the trees or knew the kinds selected; or, in short, one can see that his information is from mere hearsay. Still I have no doubt that it is to a certain extent true, for the following reason:—A gentleman would, in planting a fruit garden, with an idea of sending his surplus fruit to market, consult his own taste, and select choice kinds, planting a few trees of each so as to produce much variety of fruit in small quantities, called by the market people "cotechels." Now, these from a distance will not pay the cost of carriage, and your readers will, perhaps, be surprised to learn that our most delicious winter Pears—such as Winter Nelis, Joséphine de Malines, and Bergamotte d'Espéren, are nearly valueless as market Pears, unless grown of extra size on trees against walls. The truth is, that only a few market and gentlemen's gardeners know what kinds of winter Pears to grow for Covent Garden, and how to grow them. There are, also, but few fruit-growers who know the most eligible kinds; many of them, like the person Mr. Robson refers to, as to his fruit from 170 trees making 17s. 3d., plant too many kinds, and not the proper ones. They, in short, are deficient in that sound practical knowledge in fruit-cultivation which takes many years, and, above all, acute observation to acquire; such gardeners as one of my friends happens to have in his employ, and whom, because of his inflexible opposition to orchard-houses and root-pruning, he calls "Mr. Passive Resistance," never can and never will obtain this appendix to "useful knowledge"—How to grow fruit for market profitably.

In giving my experience in fruit-growing, I fear that I shall make myself liable to the charge of egotism, that eternal "I," which so sorely afflicts articles on gardening, will rise to the surface. In spite, however, of the obtrusive "ego," I will tell a little more about fruit-culture.

To commence with Pear trees on Quince stocks, I must go back some thirty odd years. About that time I was a great collector of fruits, and more particularly Pears. I had ransacked the whole of Europe, and whenever I saw a new name in some catalogue I ordered a tree. By these means I had formed a collection which I find on reference to my old catalogues, consisted of 918 sorts, besides many that had not been entered, so that I had upwards of a thousand nominal varieties of Pears. One tree of each sort I had planted in a large border of calcareous sandy loam resting on sand and marl with chalk stones. Well, the trees grew freely, and in process of time many of them bore fruit—the fruit of disappointment. What wretched Pears I have tasted from those trees, and how few were found worthy of trying again! As far as I can now calculate, I found one hundred varieties worthy of propagation. It is some twenty odd years since that I became deeply interested in planting Pear trees for market purposes. I thought I saw a pleasing prospect of "majestic trees" full of fruit, myself lying under their shade, with some pleasant book, enjoying the "dolce," &c., and full of agreeable anticipations as to the value of my choice Pears. To carry out my first scheme, I bought of Messrs. Buchanan & Co., then nurserymen at Camberwell, many hundreds of the grandest standard Pears ever seen, many of their stems measured from 6 to 7 inches in circumference. They were, in nursery parlance, overgrown trees, and were destined to the wood heap. I happened at that time to have made a purchase of some freehold land, and I remember bribing the farmer to allow me to plant my large Pear trees in rows among the young Wheat, agreeing to pay for every square yard taken up in planting my

trees. I had the heads of my trees cut off, and planted the stems in the autumn of 1836. They all grew admirably, and in the spring of 1838 they were grafted with the following sorts, which I then thought would make a fortune—Easter Baurré, Baurré Diel, Baurré Rance, Glou Moreau, Hæon's Incomparable (how odd it is, that this Pear, then one of the handsomest and finest Pears known, should now be a bad grower, a bad bearer, and the fruit very inferior; it has been so here for many years), and Knight's Winter Crassane. The grafts soon formed fine healthy trees, blossomed abundantly, and I was on the eve of pleasant expectation; but my hopes were in the course of a few years all crushed. I had fair crops of fruit, but my soil (or climate), was too cool, and the fine sorts above named did not ripen their fruit properly; some were spotted, some cracked, and but very few indeed were fit for the Covent Garden shops, where I had so often seen Pears of the same kinds from walls so fine and imposing. Still my trees were a beautiful sight, they were so healthy. The only sort that fulfilled my expectations as to bearing abundantly, was the Winter Crassane, of which I had one season upwards of one hundred bushels of fine clean fruit. A few were sent to Covent Garden in January to ascertain their value, which I found to be nil, for they had no flavour; the remainder were crushed for their pips, and very fine stocks they made, and thus ended my first experiment in growing Pears for market.

It was, I think, in September, 1843 or 4, that on returning from a long journey on the Continent, I paid my specimen Pear trees a visit to look over the numerous varieties, and taste and try them. To my great delight I soon observed two trees, pyramids, remarkable for the abundance and beauty of their fruit; one was the Louise Bonne of Jersey, the other the Baurré de Capiaumont, both on Quince stocks. Among hundreds of sorts there was not one that looked so full of promise as those two kinds. My mind was immediately made up. The former I determined to plant largely, and the latter to graft all my choice kinds with, for I observed that it bore equally well on the Pear stock, and gave fruit of a rich red, yellow, and russet, peculiar to this sort in the soil here, and which it still retains, being very unlike those from trees near London, which are generally covered with russet.

In the autumn of 1845 I commenced my plantation of two thousand Louise Bonne Pears on the Quince stock, planting trees three and four years old. The rows were 24 feet apart, to give room for the crops in the spaces between them, and the trees 5 feet apart in the rows. They commenced to bear the second season after planting, and produced the most beautiful fruit I had ever seen. From 1849 to 1853, both inclusive, we had here a series of spring frosts, destroying all my Pear blossoms. I began to think that my dreams of profit from Pear-growing were castles in the air. In 1854 a change in our spring climate took place, and my hopes revived; in 1855 my crop was magnificent, the Pears the finest in the market, and the price they brought very satisfactory. In 1857 I was more than ever gratified, for such an assemblage of pyramidal Pears loaded with fruit of the most beautiful colour was never before seen, they were large, and without exaggeration their colour was crimson and gold—this I have since found was owing to the soil being full of calcareous matter. It was this season that I had a visit from two experienced market gardeners from Fulham, the classic region of market gardens; "they came to look at my Pears," they said, having heard about them the previous year in Covent Garden. I felt, of course, great delight in showing them. They looked and looked at the Pears, were very reticent; but I detected some significant glances exchanged. After lunch and a glass of wine, I expressed my anxiety to know whether my Louise Bonne Pears were equal in quality to those at Fulham, knowing as I did the superiority of the soil and climate there. I addressed myself to Mr. M—, a most experienced cultivator. In reply, he said, as nearly as I can recollect, "My Louise Bonne Pears, the trees on Pear stocks, are a week or ten days earlier than yours; I shall go home and send them all to market before yours arrive, for no Pear I have ever seen can compete with them." I need not add that I felt much gratified. I sent to market that season upwards of 700 half sieves (half bushels) of Louise Bonne Pears, which made from 6s. to 8s. per half sieve, the first price for "seconds," the latter for the prime. My numerous trees grafted with Baurré de Capiaumont, were equally successful, for in one season I sent 600 bushels of this sort to market, which made from 4s. to 5s. per bushel. I felt fully rewarded for my years of care, and thankful that I had been so observant.

Since the above period I have removed all my Louise Bonne Pears, although the trees were large. Finding that they interfered with cultivation, and many of them having chlorosis from the soil being shallow, resting on calcareous sand, they are now in close quarters, and full of blossom-buds. To exemplify the fertility brought on by removing fruit trees, I may mention that half a dozen of the first Louise Bonne Pear trees planted are left in their original positions, they are large trees, but this season blossomless. I have, I fear, too lengthily thus far given you a full and particular account of my experience in growing Pears for market.

In paragraph 12 Mr. Robson admits that the Quince stock "is of service in more ways than the Paradise has been for Apples." Thanks, Mr. Robson, for the admission. Is it because the Quince is more distantly related to the Pear than the Paradise to the Apple, so that the foreign blood invigorates the tree? This is not quite in accordance with vegetable physiology. To his question, Has fruit from Pears on Quince stocks "ever excelled that grown on the Pear stock in size, flavour, or abundance?" the history of my Pear-culture is a sufficient reply. The truth is, it is answered here every autumn, and has been annually for many years.

From what I have seen of the fruit-growers of Kent, I have reason to believe them kind, good men, living on a soil so good as to make them satisfied with their lot, and not inclined to try any new mode of culture or new thing. I can illustrate this feeling in fruit-growers well-placed. It is now some thirty or forty years since I raised from a stone a Plum, which I soon found was of great value, being a constant bearer, of good colour and size, and, above all, the earliest Plum known. After the lapse of ten or fifteen years, finding it so valuable as a market Plum, and not having at that time more than thirty acres under cultivation, so that I could not plant out my large stock of young trees, I made known its qualities to the fruit-growers of sunny Kent, &c.; they would not plant it to any extent, feeling satisfied with an inferior early Plum, called the Early Violet and the Early Orleans. Soon after this, somewhat less than twenty years since, I was enabled to add to my estate by some fortunate purchases. One field of five acres, with a fine calcareous soil and south-western slope, I dedicated to Plums, and knowing well the custom of fruit-growers who planted only well-known sorts, such as that popular and excellent Plum, the Victoria, and others, all mid-season Plums, I followed my own judgment and planted three kinds, one the early seedling I have mentioned, the others Belle de Septembre and Reine Claude de Bayay, both very late; the result has been the perfect success of my calculations. For some years past I have sent hundreds of bushels of the early Plum to market before there were any to compete with them, consequently they have made double the price of mid-season kinds. Of the two late sorts the Belle de Septembre, one of the largest, best, and most beautiful of culinary Plums, has also realised a very high price, because it was so late that no other Plums were in the market; and my late Green Gages, *alias* Reine Claude de Bayay, have been sent to market when Green Gages were forgotten, so that 10s. the half sieve, or 20s. per bushel, has been no uncommon price for my two late sorts of Plums. I enter into these details to show Mr. Robson that I am not a visionary, and that I have deviated from the fruit-grower's groove to some purpose. One thousand bushels of Plums were sent from here last season, and owing to their going to market early and late, the glut, owing to the abundant crop, was avoided, and I had my reward.

I may add that the five hundred trees of the early Plum are all pyramids, kept so by slight annual pruning, and that they are planted 24 feet apart, row from row, and 10 feet apart in the rows. When I planted them I was not so wise a planter as I now am, or I should have had more than double the number of trees on the same space of ground. I never remember seeing anything in fruit-culture more beautiful than these trees were last season, every tree a pyramid of purple fruit more numerous than the leaves, and, to my surprise, they are this season covered with blossom-buds, seeming likely to bear a fine crop. Spring frosts have but little effect on this kind of Plum, hence its value. Now, it will scarcely be believed that till within these two or three years Mr. Robson's neighbours knew nothing of this valuable sort, although, according to his account, they visit other parts of the kingdom, and Belgium, &c., in search of good fruit. I have never heard of any new good kind of fruit being introduced by these gentlemen, or a new kind raised from seed. If they had read "our Journal" they would have been before their time in this matter, instead of behind it. I

found the Reine Claude de Bavay Plum in the garden of its raiser, Major Esperen, at Malines, and at once imported all the trees I could find, and they are the trees which now bear so well here. In my zeal I imported some hundreds under the name, which to my great concern turned out Coe's Golden Drop.

In giving a history of my Plum-culture, although I fear your readers will be tired of the everlasting *ego*, I feel that I ought to describe a new mode of planting Plum trees for market purposes just commenced here.

There are two kinds of Plums remarkable for the fastigate habit of the trees, for the size and beauty of their fruit—one purple, the other bright red—and for their prolific habit. Well, after closely observing these sorts for two or three years, I determined on planting them to some extent. Accordingly, last spring a plantation was formed of upwards of one thousand trees, planted 5 feet apart, row from row, and 3 feet apart in the rows. It is intended to encourage their natural Cypress-like habit by summer pruning, so that each row will form almost a hedge. In the course of seven or ten years, if necessary, every alternate tree will be removed and replanted; but in the meantime they will have amply paid their way, for even this spring many of the little pyramids are full of blossoms. By this mode of culture—and it may be followed with some kinds of Pears on Quince stocks and Apples on Paradise stocks—the trees have the full benefit of the soil, which is too often exhausted by intermediate cropping; still, a light crop in the centre of the space between each row may be taken for one or two years. The great advantage, however, derived from this mode of planting is the superior ripening of the fruit from the radiation of heat from the bare surface of the soil, a subject but little thought of by most fruit-growers.

In his eleventh paragraph Mr. Robson mentions his freedom from the imputation of "puffing any particular class of tree." I am not aware of any person being liable to this apparent inuendo; but I happen to know that two little books, published within these twenty years, one having gone through thirteen editions (13,000), the other twelve editions (12,000), have spread the knowledge of garden fruit-tree culture over the whole empire, and have relieved thousands of amateurs from the thralldom of persons calling themselves gardeners, not the true species, for a good accomplished gardener is a fine fellow, and far superior, I am inclined to think, to a majority of the trading classes, owing to his vocation bringing, on reflection, a knowledge of Nature and her handiworks.

Mr. Robson thinks that because the Filbert-growers prune their trees properly, the same would have been done by the Kentish fruit-growers if called for. The soil and climate have more to do with Filbert-culture than most people are aware of. The formation on which the soil rests suits them, for no pruning, no skill, will make them succeed in the majority of soils. The fruit-growers of Kent for some generations have felt satisfied with their orchards, and have not moved "upwards and onwards." Some day ere long the firm of Messrs. Passive Resistance, Jasper Standstill & Co., will be dissolved, and then the Kentish fruit-growers must look to it, for depend upon it many clever, energetic men will cultivate fruit in gardens and take the best market prices. I have more than once stated that fruit culture has not yet commenced, it is yet in the future; and when the above firm has ceased its operations, not only will market garden fruit-culture be widely extended (our increasing rich and luxurious population will take all that can be produced), but domestic gardening will largely increase, and orchard-houses, ground vinerias, vineyards under glass, cordon training under glass ridges, dessert Orange culture, pyramidal and bush culture of fruit trees, and other pleasant deviations from the old-fashioned routine, will be disseminated among that rapidly increasing and highly intelligent part of our population—the middle classes of our country. That great truth, "Genius cuts out new paths where ordinary mortals imagine nothing can be done," is as applicable to fruit-tree culture as to the higher arts.—T. R.

P. S.—Referring to the article by Mr. Vallance, page 270, there is not the least doubt but that the French Paradise stock is as objectionable now from its tendency to canker as it was in the time of Miller, who describes it so accurately. The sort described by Mr. Vallance is doubtless some variety of the Doucin, so much like the Pommier de Paradis as not to be distinguished from it, but still not it. I have some thousands of this sort; the trees it gives are equally dwarf with those grafted on the French Paradise; but I reckon I was cheated when I bought these stocks.

[At one time we regretted the controversy between our two

friends—for pokes were given and returned—but the preceding most useful and sound communication would remove the regret even if the pokes had been more numerous. However, we think the controversy may now close. Each has vindicated his opinions, and each, we are sure, regrets if he has annoyed his antagonist.—Eds.]

THE PARIS EXHIBITION OF 1867.

WE understand that it is proposed to hold a meeting of florists and horticulturists in the conservatory at the Royal Horticultural Society's Gardens, South Kensington, on the 1st of May, at 10.30 A.M., in order that they may have the opportunity of stating their views with regard to the great French Exhibition of 1867.

THE INTERNATIONAL HORTICULTURAL EXHIBITION.

On this day, four weeks hence, the Great International Horticultural Exhibition will be opened in the presence of one of those distinguished companies which can only be seen on such occasions; and will disclose a splendour of form, and colour, and effect such as has never been witnessed in this or in any other country. The preparations that have been made are already far advanced. The framework of the building itself is now completed, and the roofing will in the course of a few days be fixed, while the interior arrangements and groundwork have now acquired such a development as to exhibit distinctly the outline of the whole.

From the ground plan that we publish in our present Number, a pretty correct idea may be obtained of the way in which the interior is laid out; but no plan can convey to the mind any conception of the vast dimensions. When we say that the area occupied is over 3½ acres, that its length is 563 feet, being exactly the width of the Great Industrial Exhibition building of 1862, its width 293 feet, and that its height is 30 feet in the centre, some faint notion may be formed of what sort of place it is. About 55,000 superficial feet will be appropriated to the plants, which will be arranged on sloping grass banks; and 60,000 superficial feet are devoted to the promenades, which will accommodate 15,000 persons in the building, allowing 4 square feet for each person. For the Orchids and other tender plants special arrangements have been made, and an apartment 500 feet long by 40 feet wide, heated with hot water, and made perfectly secure, has been provided.

The merit of the plan, and execution of the building and earthworks, are due to Mr. Gibson, the skilful garden architect and superintendent of Battersea Park, who, with his clever son, has given his gratuitous services, and devoted himself with unwearied energy to secure the success of this great undertaking. The framework and canvass have been constructed and erected by Messrs. Unite, the eminent tent-makers and sail-cloth manufacturers of Paddington, who, in this matter, have aided the Executive Committee by an affability and liberality which is worthy of commendation.

But, say some, "How is such a vast space to be filled?" "Filled?" we say. Nay. Will there be room enough? Have we not been told of more than twenty two-horse vanloads of things coming from Waltham Cross Nurseries, as many from Slough, and Ascot, and Knaphill, and nobody knows how many from Chelsea? Then we hear of Mr. Pince, of Exeter, fired with all the ardour of early days, freighting a fabulous number of railway trucks to convey examples of those grand conifers and other ornamental trees for which the Exeter Nurseries have been so long celebrated. Then there are numerous other exhibitors who will be there in not less formidable force—from Holloway and Hammersmith, St. John's Wood and Highgate, Tooting and Dulwich, and a host of those grand private collections besides, which there can be seen nowhere else but in this country. And then there are all the treasures of Kew—its Palms, and Bananas, and other fine-foliaged things, all of which have been placed at the disposal of the Committee, will be there. There is not a nursery or garden establishment of any note in the country that will not be represented; and not of this country only, for we already hear of great preparations at Ghent and Brussels, Paris, Amsterdam, and many other places that intend to join in the honourable contest. All these varied subjects skilfully and artistically arranged over a surface of three acres and a half of picturesque undulating ground—verily it will be a grand sight!

PROTECTING THE BLOSSOM OF WALL FRUIT TREES.

I LIVE a few miles, less than ten, due north of London, and for thirty years I have grown Peaches, Nectarines, and Apricots on an open wall facing full south. During all these years I have never protected them in the least, and I have lost once now and then, yet very rarely, my crop of Peaches and Nectarines by the spring frosts, but my Apricots have never been injured.

This season my Apricots have been in profuse bloom, but they were in consequence of the mild winter so very forward, that, departing from my usual practice, I thought it only prudent to retard, if I could, the expanding of the blossoms. I suspended, therefore, over the tree a cloth supported on poles, through the sunny days, and there were but few of them, of February and the first half of March, always continuing the covering through the immediately following nights, but removing it wholly when the weather was dull and gloomy. The sequel is, that not a blossom has set its fruit, and "the Begum's" anticipations of Apricot-jam are at an end for this season; but then she has the gratification of knowing that a friend's Apricot on a west wall that has been left wholly unprotected, shows an ample crop.

Such a failure as this looks very like *propter hoc* as well as *post hoc*, and brings to mind Talleyrand's impatience of blunders, and what he said of them. I shall "protect" no more.—BETA.

[We believe that if Apricot blossoms could be kept dry, they are as well without protection. On many south walls this season we believe the centre of the blossom was injured by wet and cold, when west and east aspects escaped from being later. We notice nothing wrong in the mode of covering adopted, but it is possible that the germs of the fruit was injured before covering was resorted to. We had a box of fine blossoms sent to us to look at, and on examining them not one had a sound pistil. Most likely if you had not covered at all you would have been blaming yourself.]

A PLEA FOR EVERGREENS NOT GENERALLY GROWN.

IT IS much to be regretted that at the present time the attention directed to such plants as are likely to constitute a feature in dressed grounds is too much confined to those having only an ephemeral existence. A glare of colour for two or three months is thought to be of more importance than watching the progress of plants that may, in all probability, continue for centuries. Pinuses, it is true, are grown, and a few select species are favourites everywhere; but the mass of other trees is much neglected, and there are several shrubs of great merit which are far from so generally grown as I think they ought to be. My object in the following remarks is partly to direct attention to the merits of certain trees and shrubs, and at the same time to ask some questions as to one or two, respecting which I am desirous of further information. With these I shall commence.

First, I wish to have the opinions of those who have grown *Skimmia japonica* extensively, as to how it comports itself as a shrub. Unfortunately I have not had a chance to try it, as the soil here is adverse to it. I also desire similar information with regard to *Pernettya mucronata*, likewise a berry-bearing plant of great beauty when well managed, but which I cannot grow. *Desfontainia spinosa* I have seen in great perfection out of doors, but I do not think it is plentiful enough for general adoption there; it is certainly deserving of attention. Then we have several plants of recent introduction from Japan, some *Aucubas*, for instance. The one called *A. japonica vera* seems to be of slow growth here, but it is quite hardy I should think. Will the male one ever revolutionise the character of our old familiar *Aucuba*, which even now is not so much grown as it deserves to be? The other *Aucubas* I am not acquainted with, and I expect that they are not yet sufficiently numerous to be used in out-door work executed for effect.

Raphiolepis ovata is a promising plant, quite hardy, and I think likely to be a favourite, and the foliage being good and abundant, it will, I think, rank high amongst evergreens. I wish I could say the same of the *Cotonæsters*. *C. Simmonsi* looks very well in autumn when loaded with beautiful orange-coloured berries; but its leaves become shabby, and, in fact, fall off, and the other species seem to have too great a resem-

blance to *C. microphylla*. Nothing can be better than the latter for covering a steep bank, its deep dark-green foliage and healthy appearance rendering it very ornamental in such a position. Rabbits are, however, very fond of it, and where they abound it ought not to be planted; they are also fond of another plant, not by any means so common as it ought to be—*Griselinia littoralis*. This fine evergreen is, perhaps, more densely clothed with foliage than any plant which I know, except the Box, and being of compact growth deserves to be more generally grown. *Photinia serrulata* is too tender for most places, excepting against a wall; but I believe *Eugenia Ugni* and *E. apiculata* to be hardy enough, and well fitted for a sheltered shrubbery. Then we have the hardier varieties of the Indian *Azuleas*, which at Fairlawn are as hardy as the *Rhododendron* and look as well; and *Camellias*, too, will thrive in places where the soil and situation suit them; but they very seldom produce good flowers out of doors, as the least wet spoils them.

Many other evergreens might be named as capable of adding to the interest afforded by that class of plants—one which I should like to see more extensively grown; and I hope that those who have succeeded well with the species above mentioned, or who know of others deserving of attention, will record their views.—J. RONSON.

JOTTINGS OF GARDENS IN LEICESTERSHIRE.

LEICESTER! what thoughts arise at the mention of the name! Few counties call up more thoughts or subjects for reflection. What troubles have been there! what scenes of strife and commotion! what sermons its very stone walls preach! It is full of interest. Its Fosse road, what troops have passed along its highway!—its river Soar, with its famous bridge which Richard III. passed over to the memorable battle of Bosworth; and a tablet in the wall surrounding the grounds of A. Turner, Esq. (now famous for Orchids), tells the traveller, "Near this spot lie the remains of King Richard III., the last of the Plantagenets." Leicester! with its old abbey walls and Norman archways, where the most famous man of his day—the butcher's son, the dictator of kings—the great Cardinal Wolsey expired, teaching important lessons to yet unborn generations of the instability of human greatness when, passing through that old gateway in the north wall, he said, "If I had served my God as I have served my king." Leicester! with its fine agricultural and grazing land; its granite, slates, and coal; its wool and woollen manufactures; its rapid strides in trade and commerce; and its boot and shoe manufacture, a trade which has sprung up within the last twelve years. Trade and commerce flourish; and men of business who, a few years since, worked hard for their subsistence, now, having made their fortunes, have their handsome suburban villas, which are a credit to the town and county.

From the race-ground to Oadby, a distance of three miles and a half, is one continuous line of detached villas—neat, pretty, and apparently well kept—and I could not fail to be struck with the great and pleasing variety of trees and shrubs with which the grounds surrounding them are planted. It would be well if many of these intrusted with the laying out and planting of similar villas round London would go down there and take a lesson or two, so that we might not have so much monotony in the varieties of shrubs yearly planted. The suburban mania is extending in every direction; east, west, north, and south are heard the trowel and hammer, and long may it continue; long may trade flourish, long may our favourite horticulture find support, and the spirited nurserymen receive encouragement.

Few towns have made, and are still making, greater strides in horticulture. It is a work of time to deeply engraft a love of the beautiful in any district, particularly such a one as this was a few years since; but it has been done, and all honour to the few who quietly impressed the minds of others, and gently led them on. I dare not mention names, or I might those to whom Leicester is much indebted; they have "done good by stealth," and would "blush to find it fame." There were not many places a few years ago to interest the horticulturist or botanist, and they were far apart, but a change has come. Leicestershire can now support its floral and horticultural exhibitions in most of its towns and villages of any note. Here flowers are now grown from the lowly Pansy to the most gorgeous and rarest Orchids, and fruits from the "show" Gooseberry to the luscious Peach and Pine; and if

the Leicester exhibitors only have clear-headed practical men on their committees, and proper men for judges, they will soon have one of the most important societies in the country, and one that must influence the horticultural taste for permanent good.

I have before remarked that villas are springing up on all sides; more particularly in a southern direction are to be found the villas of the mercantile and manufacturing gentry who live out of town, in fact it is the Clapham of Leicester. I may, as time offers, note some of these places, as well as nurseries; but there is one deserving of special notice. I was informed that at Glen Magna, a village about seven miles out in a southern direction on the old turnpike road to London, a gentleman, one of the "self-made men," was making a new place. I started off one day to see, if possible, if it was equal to report. On making inquiry, I found the place was called "Rupert's Rest," and that it was the residence of T. Crick, Esq. I fortunately found Mr. Crick at home, and on stating my errand he, in the kindest manner possible, showed me all over the premises, which I will endeavour to describe.

The house was originally a small old country villa, with very trifling grounds round it; traditionally, and I believe with more truth than many other traditions, the house in which Prince Rupert slept, surrounded by his soldiers, the night before the battle of Naesby. But what a change of scenery now! Ah, Rupert! your soldiers would not so many of them that night have had to sleep in the open air, for the place is indeed altered. A new wall faces the road, with entrance gates to front and back. I am conducted by Mr. C. through the back entrance into a yard, having the house on the left hand, with part of the old boundary wall still standing, and on the right are new stables, coach-house, cow-shed, &c., with a fruit-room over the last, and a fowl-run at the farther end. The glass is opposite me; the first house we entered was a sunk range in three divisions, intended for Peaches in one, Figs in the centre, and a succession-pit for Pines in the other end. The Peach trees had not done well, but the Fig trees were growing very freely, and the Pines were just commencing. This house is sunk in the centre or pathway, is span-roofed, and each light is made to open for ventilation. It is 55 feet in length. The first object that attracted my attention was a batch of seedling Figs which had been sown by Mr. Crick himself, and which were about 12 inches high; there were also some seedling Grape Vines from a foreign source, and a quantity of seedling Pelargoniums, a cross between Mrs. Pollock and Madame Vaucher, but not sufficiently large to give one a correct idea of what they were likely to be, but one or two had a pretty, clearly-defined zone, as in the mother plant, Mrs. Pollock. There was also hanging from one of the division roofs a good plant of *Ipomœa Horsfalliæ*, which had been very full of flower, and there was a variety of other plants of which I made no note.

Ascending three or four steps out of the Peach-house, we next enter a fine curvilinear range with a lantern roof for ventilation; this house is of iron and glass resting on brick walls, is 105 feet long, 20 feet wide, and 15 feet high, and is in three divisions. The iron ribs, which are $1\frac{1}{2}$ inch wide by $4\frac{1}{2}$ deep, as well as the bars for the glass, are neatly put together with screws and bolts; on each side are swing-sashes made to open by a very simple contrivance of long rod, wheel, ratchet, screw, and lever; and advantage was taken in building the walls to let in ventilators under the heating apparatus and pipes, so that the cold air passing in might enter a partially confined chamber over the pipes supplying surface-heat, ere it came in contact with the plants—a point too often forgotten in erecting houses especially intended for winter work. The lantern on the top of the roof is also made to open in three lengths by a simple contrivance of chain and leverage, so that there is ample ventilation yet simple in its contrivance. On entering from the lower range you find opposite you glass folding-doors leading into a pretty ornamental flower garden, but passing to the right hand you find there is a bed built on arches on each side of the house, with four rows of four-inch pipes under them for bottom and top heat. In the centre is a bed in two divisions, also with pipes for bottom heat; and in the centre of one of the four-inch pipes is inserted one half an inch in diameter, and having a tap to supply hot water, so that in watering the plants the gardener has the water at any heat he may think fit to use it. In the right-hand bed are planted a quantity of Grape Vines. "These," said Mr. Crick, "I imported from the continent; those on the other side are the best kinds I could buy from the English nurserymen, al-

though both will be cut down in the spring and be allowed to make another year's growth ere they carry their first crop of fruit;" yet the difference in growth and strength was very perceptible, although all were treated alike. I would certainly advise lifting the whole of them before they make another year's growth, filling up the borders to the top of the curb with partially decomposed chopped turf, and planting them on the top with at first a slight covering of soil over the roots. In this house was a general collection of plants such as are usually found in a gentleman's place.

We now pass through a glass door, and we are in the tropical end, and here we find a good selection of stove and ornamental-foliaged plants, which, when fully grown, will merit distinction. The end wall, parting off the potting-shed, is covered with glass cinders, with pots and niches for Ferns, &c. This cinder is formed from old glass bottles, &c., run together in a furnace, and will have a pretty effect when filled. We next look into the potting-shed or, as Mr. Crick called it, the workshop, 19 feet long and the same width, nicely heated from the boiler and pipes, which are below. The boiler is one supplied by Apply, Renshaw Iron Works, near Derby, and here I may remark that the whole place is supplied with bottom and top heat by the same boiler. The pipes, four-inch, are all separately connected with the boiler by two-inch pipes, with stop-cocks, so that each house can be worked separately. I believe there are nine of these stop-cocks.

In this shed I saw a quantity of bulbs for spring work, and I was much pleased with the nice genial warmth; here there is no need to fear bringing out a plant or two to repot, clean, or tie into form from a stove or intermediate-house as is too often the case. I have often seen plants taken from a warm house to a shed almost at the freezing-point, to be repotted or for some other operation to be performed, to the detriment of the plant and the injury of the gardener's constitution. Here everything appears to have been done after well-matured thought.

We now return through the stove into the house we first entered, only on the other side, until we come to another glass partition. We enter here, and find the house filled with a stage in the centre and on the sides. The end is covered with glass cinders, but here is a portico in artificial rockery, with white spar pillars and capitals, which when filled, as it has been suggested, with *Mesembryanthemums* and other succulents, will have a pretty effect—in fact this will be one of the most handsome pieces of artificial rockwork I have ever met with. I much admired the effect of the paths—"Minton tiles," of a pretty design. Passing through the portico and pillars, we enter the conservatory adjoining the dining-room. This has also an iron and glass curvilinear roof, and from the dining-room there will be a very fine view when the climbers have made their full growth and are hanging in festoons, the glorious *Tacsonia manicata* and *ignea* (I believe it was) mingling with the variegated *Cobœa*, and the walls covered with *Lycopods*, Ferns, &c.; and on looking through a glass door at the other end, which is 57 feet from the dining-room, some ribbon-borders are seen on the outside. I asked Mr. Crick who was the builder, and his reply was, "We did it ourselves with our own men. I carried out my own ideas." Then, I say, all honour to men of business who earn their own fortunes, and can and do set their own ingenious faculties to work from a pure love of horticulture.

We pass out into the grounds—here are some handsome polished granite and marble vases, tazzas, pedestals, &c., some of great cost from the Continent. Around some of them there are pretty designs in pebbles of various colours brought from Kent and Surrey. I also noticed a pretty moss house under some trees, some more massive ornamental vases opposite a pheasantry and aviary, rockwork, and a cinder flower garden with Roses. We still keep moving—presently we come to the geometrical garden. Here the frost had done its work, so that I could not see what the appearance had been, but I understood that there was to be a rockery formed in some part adjoining. Here were a nice lot of fruit trees in pots, preparing for a large orchard-house about to be erected; also a small vineery of which the roof, being too flat, was to be raised at the back. Next were several pit-lights full of dwarf seedling *Chrysanthemums*, but none was in bloom.

But what have we here? Why certainly these are Peach trees. Yes, and I exclaimed, a new idea, "good walls for the million." Do not laugh, good readers, at the idea, it is an accomplished fact. A Willow wall to train Peaches on, with the wood of the latter good, firm, and brown, buds plump, and,

what was more, I looked at the old foliage to discover traces of red spider or thrips, but could not discover any; yet adjoining was a brick wall, and there was no need of a magnifying glass to find traces there. Now for the formation of the "Crick wall."

Mr. Crick was troubled with his neighbours' cattle in a field adjoining his garden, and having a lot of Willow wood lying about, which had been cut down during the alterations, he had it cut into lengths and split flat, or as flat as he could, some posts fixed into the ground, and the strips nailed longitudinally to the posts. This wall is about 10 feet high. There has been no effort to stop any openings between the pieces, and the wood of the Peach, Plum, and three Apricot trees are as firm as that of others on a brick wall. I thought the idea might be of service to some of the readers of the Journal. I would suggest Larch posts, charred before they are let into the ground, to any one desirous of putting up such a fruit wall at a small expense. A good crop of fruit had been ripened.

There is not room in Mr. Crick's place for display in the natural or gardenesque style, but when Mr. Crick has fully carried out his ideas it will be one of the prettiest gardens in the artificial style that can be found in the county, doing credit to all who are concerned. I am sure any one wishing to spend an hour, and who has a love of gardening, will, on presenting his card, meet with the greatest courtesy from Mr. Crick; and, for his kindness and affability, to him are due the thanks of—NICKERBOUR.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE Broccoli and winter Greens are coming off, the ground should be deeply trenched, the stems being laid at the bottom, and quicklime strewed over them; also, if the ground is intended to be again planted with any of the Brassica tribe, it should have some manure incorporated with the soil; but it is best at all times to change the crops as far as practicable. If, however, from circumstances of soil or situation it is necessary to plant the same kind of crop repeatedly in the same places, such parts should have repeated turnings to expose fresh surfaces to the influence of the atmosphere. *Carrots*, sow the main crop in drills from 12 to 15 inches apart, covering the seeds evenly to the depth of about half an inch. Those for early and late use will be drawn while young, and may be sown broadcast in beds, or in lines 9 inches apart. *Cauliflowers*, keep the ground well mowed about them, as also about Cabbages. *Beet*, sow a full crop in drills about 1 inch deep, and from 15 to 18 inches apart. If possible, select a dry day, when the ground is in good working order for putting in the seed. *Cucumbers*, the young plants intended for the ridges to be kept stopped, and repotted if they require it. Sprinkle the plants in the frames early in the afternoon and close up; water more liberally round the sides of the frame when the heat of the day dries the soil. *Kidney Beans*, sow on a well-sheltered border, also a few Scarlet Runners and Haricot Beans; but we find all these succeed so well transplanted that it is best to provide for contingencies by sowing them in pots or boxes, and germinating them under glass; when well up, remove them to the open air, cover at night, and transplant in the beginning of the second week in May; they will come into bearing more than a week before those sown in the open ground, and will continue to bear quite as long; add to this the certainty of a crop, and the facility of protecting them in their earlier stages when they are so apt to be nipped by the spring frosts. *Peas*, continue to earth-up and stake them as they advance, taking care to fork-up or otherwise loosen the ground between the rows after the staking is done; let this be followed up, even if Spinach is growing between the rows, as that will be benefited by having the surface well stirred about it. Keep up successional sowings of Lettuces, Spinach, Radishes, and salads.

FRUIT GARDEN.

The process of disbudding Peach trees will now be in full operation. Watch the growth well, and remove but a few of the shoots at a time. Endeavour as far as possible to keep beforehand with the growth in disbudding, and not behind; for if you are behind you are often tempted, nay almost obliged, to take off more shoots at once than is proper, and the check thus given to the flow of the sap has very often the effect of causing the fruit to stop swelling, and eventually to fall off. Remove all the foreright shoots from Apricot trees, also a portion of the side shoots, but endeavour to distinguish those

which are likely to form short fruit-bearing spurs, which must always be left. Thin, also, the young canes of Raspberries to the number necessary for next year's crop. By this means the canes will be stronger, and will ripen better.

FLOWER GARDEN.

The cultivation of annuals for garden decoration has in some degree given way to the more permanent class of bedding-out greenhouse plants; yet some of the former will always find a place in the best-arranged gardens, and a pretty general selection should at the same time be grown for filling up vacancies in borders of herbaceous plants, bulbs, &c., and particularly for dressing-up the margins of shrubberies where the space between the line of turf and shrubs may be occupied with them, so as to hide the bad effects which bare soil always produces, and afford a gay appearance through the summer, and this at a trifling expense. For the latter purpose the present will be a favourable time for sowing, the ground having previously been well dug and prepared. The varieties are so numerous that it is scarcely requisite to give names; we will therefore only observe that the seed should be sown thinly, and as soon as the plants are large enough they should be well thinned to allow a free growth. Where the possessors of gardens can enjoy their country seats through the months of March, April, and May, it becomes an important matter to provide abundance of very early spring flowers. The early-flowering bulbs are too well known to need comment here; there are, however, a few old-fashioned plants which should never be lost sight of, and which should greet the returning spring from every nook and corner. Of such are the following:—The blue and white Squills, the Sisyrinchiums, the Dog's-tooth Violets, the Pulmonarias, the *Omphalodes verna*, the *Arabis* and *Aubrietias*, the various *Primulas*, with self *Auriculas*, and the lovely little *Sanguinaria canadensis*, not forgetting the old Christmas Rose, which forms as it were the connecting link between the expiring year and its successor; the *Colechicums*, autumn *Cyclamens* and winter *Aconites* having duly ushered it in. Such should be much more encouraged than they have been, for they must ever be favourites with the many. Amongst shrubs, too, the *Cornus mascula*, the *Mezereon*, the *Cydonia japonica*, the *Chimonanthus fragrans*, the *Ribes*, *Corchorus*, &c., should be much grown.

GREENHOUSE AND CONSERVATORY.

Any attention which will serve to prolong the beauty of the Azaleas and New Holland plants, &c., with which the show-house should now be gay, will be well bestowed, as where these are over it will in most cases be impossible to furnish the house with equally handsome specimens and the same variety of colours, &c., which these afford. Get shading into use without loss of time; also carefully examine the plants on the forenoon of bright days, and see that none of them are suffering for want of water, for with bright sunshine accompanied with drying winds, it will be no easy matter to properly supply plants with water, particularly specimens that may be potted. In ventilating, endeavour while parching winds prevail to avoid allowing currents to blow through the house, especially near recently-potted specimens or plants not long brought from stoves. Bring forward the stock of plants recommended for blooming in July and August, by shifting such as require it, and allowing them more room. *Kalosanths* will require neatly tying-out; these form beautiful globular-shaped plants by a little management. *Fuchsias* will require a second shift, which should now be into their blooming-pots, using a light, rich soil for the purpose; also the different varieties of *Nerium*, so seldom seen, and yet we scarcely know more beautiful plants or any that repay cultivation better. Look to Scarlet *Geraniums* grown for specimens. Attend to repotting such as have been started after being cut back, and keep them moist and rather close until the roots have taken hold of the fresh soil. Give frequent attention to climbers in free growth, regulating the young wood before it becomes entangled. Keep the conservatory as cool by day as is consistent with the health of the inmates; this will keep the plants longer in bloom and to more enjoyable for parties seeing them.

STOVE.

Give every necessary attention to softwooded plants in free growth, keeping them near the glass and regularly stopped, so as to secure close, compact growths; also attend to supplying them with plenty of pot-room. Give air freely at every favourable opportunity, but guard against drying currents. Give proper attention to *Achimenes*, *Gloxinias*, and other summer and autumn-flowering plants. The latest succession of *Achimenes* to flower late in the autumn should now be placed in

heat. Repot and propagate Begonias. This is one of the most useful families of plants that can be grown. Orchids are now progressing fast, and will require attention in shading daily and gradually increasing the humidity of the house, so as to keep pace with the increase of solar light and heat. If the roof is covered with creepers, a little management in training them is required to effect a judicious shading of the plants beneath. See that plants on blocks or suspended in baskets are not allowed to get dry, which would have the effect of causing a check to the young growth, which should be encouraged as long as possible to obtain strong, healthy plants.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Put in the main crop of Carrots in good order. Planted a lot more Potatoes to succeed the earliest out of doors. Sowed just a little Beet for early supply, as May is soon enough for the main crops, small clean roots being more in demand than large ones like Mangolds. Planted out Cauliflowers; watered and earthed those under glasses. Sowed the main crops of Borecole, Brussels Sprouts, Savoys, and pinches of Broccoli and Cauliflower, reserving the main sowing of Broccoli till a little later; these were branched and netted. Sowed also Turnips and Radishes, and secured by netting, generally sowing the two together—the Turnips 2 feet apart, and the Radishes between them, for the latter will be all gone before the Turnips occupy the ground. Gave plenty of air to Turnips, Radishes, Carrots, Potatoes, Lettuces, &c., under protection. Sowed Lettuces in the open ground, and transplanted those raised under protection. Have had more bolted Cabbages this season than we ever had, though the seed was sown in August—a circumstance partly attributable to the mild winter and the sharp frosts of spring, and partly to the hearts having been nipped by pheasants. Sowed plenty of garden Beans and Peas in semicircular drain tiles under protection, the young plants to be planted out and staked when several inches in height, for not a Pea, and scarcely a Bean, have we left, except those which were planted out, as the whole from three sowings have been cleared off by pheasants, though we thought we had beaten them by branches, strings, and ground being all smeared with tar. It did keep them off for a few days, until they became so determined that they did not care about tar on their feathers. We find that nothing will keep them off except small netting, either wire or string, so that they cannot put their heads in. We were in hopes that the tarring alluded to last week would have kept them at bay. We could not with propriety withhold this statement as to its inefficiency.

Turning from such outside annoyances, it is pleasing to obtain such gatherings of Sea-kale, Kidney Beans, Potatoes, and to see Peas coming on so nicely in the orchard-house. These orchard-houses are very valuable even for the production of early Peas, Lettuces, &c., with little trouble in spring. We thought we might venture seed of Kidney Beans out of doors, but a few sown have also been torn up; and we must sow them, too, in small pots, and then transplant. The next Peas we venture out of doors we shall stick as soon as sown, placing the stakes at least a foot from the row, running a tarred string on each side along the rows of stakes; and then the space between the latter we will stick with brushwood, and that may keep the pheasant's bill at a distance. Planting out when from 4 to more inches in height and staking at once is the safest method, except wire guards, or using string nets with small meshes, so that the gardener shall not be blamed for hanging the favourites.

FRUIT GARDEN.

Went on disbudding or dis-shooting the trees in orchard-house, in which the fruit is set so thickly, that one in a dozen, or twenty or thirty in some cases, will be enough to leave. Proceeded in dull days, and night and morning, with thinning Grapes, and attending to other work much as stated in previous weeks. We ought to have mentioned above, that though the tar has not quite kept off the pheasants, we have as yet been no more troubled with vermin in the Cucumber-beds, and that we have not perceived one single fresh mole-run on the premises since we dropped a little tar in the runs about three weeks ago.

ORNAMENTAL DEPARTMENT.

Here we have not been able to overtake the half of our work. Turfing, much needing to be done, we have been obliged to defer till we have a showery day. Lawns have been well rolled

preparatory to mowing, as the grass is now growing vigorously, and one of the least seen but most expensive things about a garden, will be wanting continual attention. In the general routine of gardens, a large lawn is constantly demanding attention from other departments where labour would be more profitably employed. A vast number of proprietors fail to perceive that it is better in every way to keep a rood, or an acre, in first-rate order, than ten roods, or ten acres, that always need attention, and never receive so much as ought to be given. Of course, we are well aware of the grandeur derived from a large lawn of tens of acres; all we contend for is, that there is anything but grandeur in attempting to keep up a number of acres, as is often done, with the labour power fit only for a small proportion of these acres. With all our advantages from mowing-machines, Daisy-knives, &c., it is generally best in particular lawns to run the scythe over them the first time.

Many herbaceous plants may still be divided, and such plants as Daisies, Primroses, and Polyanthus may still be divided in shady places, especially as they do all the better for transplanting every year. Polyanthuses are now obtained very fair from our seedsmen, and at one time we used to grow a great many of these border flowers; but since we have had so many birds about it is of little or no use, unless they were all securely netted, as the birds were sure to pick all the flowers as soon as they expanded, or even before they opened. The little honey at the bottom of the cups might be an inducement, in addition to the love of mischief. We have seen a good-sized basketful of flowers cut over in a forenoon.

The borders are now in good trim for sowing all the hardy annuals. Where beds are made of them they will come more regularly now than when sown earlier, and they will want but little looking after. Unless where beds are made, or lines of colour are desired, there is no better plan than scratching a circle with a stout stick in the old-fashioned way, sowing thinly in the rut, covering according to the size of the seed, and thinning the seedlings after they are large enough to be handled.

Half-hardy Annuals we often sow at this season in an earth pot, pricking-in some rotten dung on the surface, levelling it, and then placing some nice fresh soil on the surface. We then sow, cover with fine soil, patting down, and place under moveable sashes, kept close until the seedlings appear. Asters, Stocks, Marigolds, Zinnias, Indian Pinks, &c., do very well thus treated, without a hotbed of any kind, and being in the ground can look after themselves better than if sown in pots. Everything in a pot requires watering, and is subject to much greater changes than if the plants had been in the ground.

Primula sinensis, *Cineraria*, &c., should now be sown for winter-blooming. The best plan is to use well-drained pots or pans, and light sandy soil, with a little fine leaf mould or peat; press the surface level, sow the seeds regularly, cover slightly with sand or very sandy soil, press again, cover with glass, and a piece of paper over it, water in three or four days, and keep rather moist and close until the seedlings appear, and then give more light and air. Good plants of *Primulas* now done flowering may be divided or reduced, fresh-potted, and grown on again, and will make fine plants if first potted in small pots, and larger ones given as needed. These will bloom before the seedlings, and come in late in autumn. Good kinds of *Cinerarias* having nearly finished blooming may be cut down and planted in a shady place, where they will produce nice sucker offshoots, each of which when potted may be grown to be a large plant. Early herbaceous *Calceolarias* may be treated in a similar manner; and every shoot taken off towards autumn, with incipient roots, will make a better plant grown on and shifted from pot to pot than could be obtained by any doctoring or treating of an old plant that had once flowered. This is the secret for keeping on favourite kinds of the herbaceous section true. One healthy shoot in August may be a plant half a yard across in April and May.

Made up a temporary protection between two pits, and there removed quantities of Scarlet Geraniums, &c., in boxes, which we have not been able as yet to plant out temporarily or pot, but to some of which we will do so as soon as we can. We wanted all these cleared out of vinerias, &c., as, though we have kept them back by a cool temperature, the heat the Vines will now require will be too much for the Geraniums, and if continued longer would make them tender. Besides, we want room to go about the Vines to rub off extra shoots, and room on the ground for Fuchsias, Camellias done blooming, &c.

Commenced moving *Calceolarias* from striking-pit, and turning them out into earth-pits, where they will have a month or

so to grow and be well rooted for ultimate transplanting. This ought to be completed soon, for the plants are now mostly healthy and strong; in fact, we have for a great many years had little trouble with these shrubby bedding *Calceolarias* ever since we made them complete strangers to artificial heat from any source, and especially fire heat in any shape.

We have not been able to put in enough *Verbenas*, &c., and to save trouble we have made up four lights on purpose, covered by two frames of two lights each. These had been used for other purposes, as Asparagus and Radishes, and the soil being removed, the beds were turned up, and mixed with a foot of hot tree leaves and dung, between 6 and 9 inches more were added to the surface, well trodden, then about 3 inches of rotten dung and leaf mould placed on the surface, well beat n, and 3 inches or so of light sandy loam put over all, and then a surfacing or scattering of drift sand. In this the cuttings were dibbled about 2 inches apart, and we shall not meet with our usual success if we do not obtain nice, bushy, healthy plants in a month. We would have liked the cuttings to have been in eight days ago, but most gardeners know what it is to be unable to do as much as the head and judgment would wish.

All plant and other houses during these fine, sunny days have made great demands on the watering-pot, and to save this in some measure and prevent the plants feeling the change so much from dulness to brightness, &c., scattered the glass in many of the houses with water coloured merely with whiting. Wednesday being such a bright day, we gave a slight spattering to the glass of the orchard-houses. The frames we have spoken of above for cuttings we whitened slightly inside of the glass, and in ordinary weather that will suffice; but on days like Wednesday a little extra shade must be put on outside. We admire blinds for all houses, and the advantage of them is that they need give no shade except in sunny weather; but there are many places where the expense of shades must not be thought of, and simple modes must be resorted to.

We find we have neglected to say that the *Calceolarias* turned out into earth pits will receive a little protection from calico, old mats, straw hurdles, wattled hurdles, &c., and being watered when turned out, they will receive little more until final planting-time.—R. F.

COVENT GARDEN MARKET.—APRIL 21.

TRADE is still dull for the season, and scarcely any alteration worth notice has taken place. A few dessert Apples and Pears may still be had. French produce in a fresh state comprises Lettuces, Endive, young Carrots, Asparagus, new Potatoes, Artichokes, and Peas. The first out-put of Asparagus of English growth has come to hand this week; we have also to report large arrivals of new Potatoes of good quality from Malta and Lisbon, also some from Cornwall.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Sowing BUCKWHEAT (*Cambrian*).—The best time for sowing it is early in May.

BOOKS (B. Z. X).—"The Gardener's Magazine of Botany" ceased to be published fourteen years ago. (F. W. L.).—There is no botanical dictionary such as you inquire for. London's "Encyclopedia of Plants" gives the information you need, with very numerous drawings of them. It is published by Messrs. Longman & Co. (S. M.).—Dr. Hogg's Fruit Manual, Third Edition, will be published on the 1st of May.

OLEA FRAGRANS NOT FLOWERING (*An Old Subscriber*).—We think that your plant will never flower unless you give it more encouragement. You will do well to thin out the head and cut it in now; and when the plant has broken, and made new shoots an inch or two in length, pot it, removing as much of the old soil as can be done without destroying the roots. Pot it in the same size of pot as before, draining well, and employing a compost of turfy sandy peat and fibry loam in equal parts, with a free admixture of sand. Syringe the plant frequently, and keep shaded and rather close for a few days; then give a light and airy situation, and when the pot becomes full of roots give a shift into a 15-inch pot. Give plenty of air and light, and you will be rewarded by flowers in due time, if you secure a good growth, and have that well ripened by autumn. In winter keep in a cool house just free from frost.

ACACIA BRUCEANSA NOT FLOWERING (*Idem*).—The beauty of this consists in its foliage, and it is not a shy bloomer when it is liberally treated and has plenty of room. You do not give it one-tenth the encouragement it requires. In order to flower, it should be planted out in the border of a cool well ventilated greenhouse, and have abundance of head room, and light and air from all points; not that it will not flower if grown in a pot, but it needs considerably more encouragement than *Acacia armata*, *A. Drummondii*, and *A. grandis*, which bloom and do well with a very moderate amount of pot room. Give it more encouragement, and it will be hard-ome in foliage and bloom in due season.

ORANGE TREES SYRINGING (*Idem*).—It is well to syringe Orange trees up to the time of the blossoms expanding, but to discontinue the syringing for a short time, or until the flowering is over, then syringe as usual.

APPROPRIATE PRUNING (*Idem*).—The shoots 1 and 2, being unhealthily, had better be cut in to good sound, plump eyes lower down; and the other shoots should be reduced to correspond, or you will have a lopsided tree. If you cut in the shoots 1 and 2 to half their length, that on the right, 30 inches in length, should be reduced to 15 inches; the one on the same side, 24 inches long, should be cut in to 12 inches; that above on the same side, 16 inches long, to 8 inches, the leader being reduced half its length.

FRAME FOR CUTTINGS (X. Y. Z.).—The best plan is to make up a bed of leaves or dung about a yard in height at this season, and 9 inches wider than the frame all round, making the bed a foot higher in front than at back. On this bed set the frame, putting on the lights, and in about a week the heat will have risen; then take off the lights, level the surface, and cover it with a couple of inches of fine rather dry soil. The next day the bed will be ready for the pots or pans of cuttings, and the Cucumber seeds may be sown at the same time in a pot by themselves. When the first rough leaves show pot the plants off two in a pot, and grow on, pinching out their points at the second rough leaf. You will obtain two batches of cuttings and seeds from this bed, and Cucumber plants for the bed. In order to make a permanent setting for a frame, excavate a pit 11 feet wide, or 12 feet allowing for walls, and the length of the frame, which, if we understand your letter, is 9 feet. At the sides and end of this pit, which should be 2 feet 6 inches deep, have a 4-inch wall built of the depth of the pit. Then have an upper course of brick-on-edge, which will project on to the ground level half a brick, and consequently have a straight face inside flush with the 4-inch wall. This upper course will not be required at the ends, for on that the frame will rest, and both ends are to be taken up 1 foot more. Now build two walls pigeon-hole fashion from the bottom of the pit, the width of the frame apart, so that you will have an interval of 2 feet between these walls, which are to carry the frame, and the outer side walls. Take the inner walls 1 foot higher than the side walls, and on this place the frame, having first found means to send the Cucumber plants in a neighbour's frame for a few days. The cuttings and seeds, it is presumed, will by this time be cleared out of the frame. Upon the pigeon-holed wall the frame is to be fixed, the wall at back being carried high enough to give the lights a fall of 1 foot 6 inches in their length. The upper course of bricks should not be pigeon-holed, and the frame should be laid in mortar. A 4-inch wall will be ample. You may divide the frame by carrying up a solid 4-inch brick wall, so as to come in the centre of the rafters, and thus partition off one light, in which you can grow Cucumbers; and the other you can use for Melons if you do not require it in summer for plants. You can fill the pit to the light with dung and leaves well trodden down, and these materials will settle sufficiently to allow room for soil and the plants. The heat when declining can be renewed by filling up the two-feet-six-inch spaces with the mowings of the lawn, weeds, &c. The linings should be kept higher than the pigeon-holes, and it will be well to line only one side at once. The pit should have an open situation, the lights sloping toward the south, and it will be all the better if protected from the north.

CALCEOLARIA CUTTINGS (*Idem*).—*Calceolaria* cuttings put in now would become nice plants for planting out during the early part of June, but you must strike them in a mild hotbed.

GUANO WATER FOR LAWN (*Idem*).—You may give a good drenching of guano water at the rate of 1 oz. to the gallon of water during dry weather, but unless you do it effectually it is only labour lost. A sprinkling of the best Peruvian guano, freed of the lumps, applied at the rate of 2 cwt. per acre, in the first moist weather in May, and again in June, equally distributing it over the surface, and allowing the rains to wash it in, will be found more effectual than four times the weight applied in a liquid form in small quantities at a time.

GARDENERS' TICKETS FOR THE INTERNATIONAL EXHIBITION (*An Old Subscriber*).—You can have one for yourself and one for your apprentice, but no female will be admitted by a gardener's ticket. Postage stamps may be sent in payment for these tickets. There will be a shilling admission day at the conclusion. You will see by the advertisement to whom you must apply.

CINERARIA SEEDLINGS (J. F.).—Although much bruised and faded, the pups could be sufficiently examined to discern that they are all inferior to many others of the same colours named and long known.

PINE APPLES (*Old Subscriber*).—We could not tell the names from seeing the leaves only. The lessons on botany will not extend for more than three or four more Numbers, we believe.

MUSHROOM-BED UNPRODUCTIVE (*G. Williams*).—We have little hopes of the Mushroom-bed coming into production that was spawned in November and has yielded no Mushrooms. What the cause is we could not say unless we knew more. The spawn might be bad, or the bed might be too hot, or too wet, or too dry.

LEAN-TO VINERY (*A Subscriber*).—Your border 5 feet wide will do for an eight-foot-wide house, more especially if you have a border also inside, and plant the Vines inside, with means for the roots finding their way outside. For such a small house your five-inch metal pipes will do for a three, provided you have a sort of brick cesspool at the turn-angles into which the pipes terminate, and this being covered with a tile, you can raise the file at any time, and run the brush through the pipes. This will require to be often done in such narrow pipes.

PEACH AND NECTARINE BLOSSOMS FALLING (*E. C.*).—We have closely examined the blossoms sent. The male fructification seems strong and vigorous, but the female parts of the flower very weak. We attribute this to three circumstances: First, the youth of the trees, having only the growth of 1865—that is, if the trees were young when planted. Secondly, their free growth instead of that being arrested last autumn. Thirdly, the too great dryness at the roots in spring. Greater dryness in the autumn, and moisture at the roots given gradually after Christmas might have kept the blossoms on. In the case of such young trees, however, a quantity of fruit this season would have been anything but an unmixed advantage. The young growth seems all right, and we have no doubt that the trees will do well next year. A few blossoms fell from some of our trees that had become rather dry, but it would have saved much labour in thinning if more had dropped. See what has been said frequently in "Doings of the Last Week" as to watering gradually when the soil becomes dry. Dryness is a great help to ripening wood in the autumn. If the dryness is continued until the buds swell, the flowers are apt to drop or be imperfect. If, after such dryness, all the roots are soaked at once, the too great stimulus is apt to throw the buds off. Moderate moisture after Christmas is the easiest and safest plan for beginners.

FLOWER-BED (*G. B. B.*).—Your bed would be improved by mixing *Ricinus barboensis*, *microcarpus*, and sanguineus, with *communis*, and such *Cannas* as *Warszewiczii* and *discolor*, with *indica*; then as you propose; but a band of *Golden Chain Geranium* with the flowers taken off would greatly improve all.

AEIDES ODORATUM LEAVES SPOTTED (*J. Bailey*).—The spots are caused by a parasitic fungus, such as is depicted in the first Number of the "Journal of the Horticultural Society," published last January.

BEGONIA FUCHSIODES AND **B. KNIGHTI** NOT FLOWERING (*Idem*).—Your plants do not flower because you keep them too warm and close, and they consequently grow amazingly, but do not bloom. Cut away all the old stems, repot, and encourage the young growths, giving plenty of air, with all the light practicable. Secure a good growth, ripen it well by exposure to light and air, and dryness at the root, and keep the plants in a temperature of from 50° to 55° in winter, and they will assuredly bloom; but you must give them a rest instead of keeping them constantly growing as we imagine you do.

BEDDING-OUT SEEDLINGS (*Eboracum*).—*Amaranthus melancholicus ruber*, *Petunia*, *Verbena venosa*, *Phlox Drummondii*, sown in a hothed in April for bedding, will only need pricking off when sufficiently large to handle; afterwards continue to forward them in heat. They will make nice plants for planting-out by the end of May, and those cultivated for their flowers will bloom well late in summer and in autumn.

MEYENIA ERECTA AND **BOUGAINVILLEA SPECIOSA** (*A Subscriber, Bradford*).—*Meyenia erecta* is a stove plant, and requires a compost of turfy fibry peat and loam in equal parts, with a free admixture of silver sand. It requires plenty of air and light, with good drainage, and is then a free-blooming plant, needing well cutting-in to keep it compact. The *Bougainvillea speciosa* needs a warm greenhouse, and should be encouraged to make a good growth in spring, and by August be exposed to the full sun in a greenhouse, with abundance of air, keeping drier by half at the root than when growing. The main point is, obtain a good growth and well ripen it. Any further information we shall be glad to furnish.

INSECT IN TAN (*H. A. G.*).—It is an *Acarus* or Mite, quite harmless, and living on decaying vegetable matter.

BREGMANZIA SUAVEOLENS CULTURE (*J. J. D.*).—The plant would do admirably planted-out in the border of the conservatory, but it requires abundance of air and light. It must be kept dry at the root in winter to induce rest, and would not, therefore, do planted-out in the borders of the conservatory in which the *Camellias* are; but you might partition off by a brick wall a part of the border for the *Bregmansia*. Drain it well, and for soil use 15 inches of tury loam two-thirds, and one-third leaf mould, with a free admixture of sand. A pit 18 inches square would do, top-dressings of rich composts being given in spring. The plant must be syringed freely in summer to keep down red spider, be well supplied with water, and occasionally with liquid manure. Diminish the amount of water in October, and keep the plant dry in winter. In spring cut-in the head, thin it where too thick, and merely shorten if not too thick. Frequent syringings and copious watering will induce free growth, and the plant will flourish, only it must have plenty of light and air and be kept free of red spider.

CEBRONELLA CANARIENSIS (*A Subscriber*).—This, usually called *Dracopcephalum canariense*, *Cannary Dragon's-head*, or *Bahn* of *Gilead*, belongs to the *Lamiaceae*, or *Dead Nettle* Natural Order. Height, about 3 feet; leaves green, and the size of those of the *Archangel* or *Dead Nettle*; flowers, pale purple; the plants not more than 2 feet apart in a bed. It requires a slight protection in winter.

RHODOENDRON (*C. F.*).—Decidedly it is not *Faleoneri*, which is white with a chocolate-coloured spot. It appears identical with that shown by Mr. Cox at the Floral Committee last Tuesday under the name of *R. campylocarpum*, but which does not correspond with the plant figured under that name in the "Botanical Magazine" for 1857. Mr. Cox, we believe, has compared his plant with Dr. Hooker's work on *Indian Rhododendrons*, and considers it is the true *R. campylocarpum*.

NETTING TO EXCLUDE BIRDS FROM CHERRY TREES (*H. C.*).—When made on purpose for this, a one-inch mesh will not be too close, as small birds are apt to wriggle through. Very often it happens that netting of a large mesh is used and put on double. It is not advisable to tighten netting at any time; let it hang loose and free, and the mesh will be closer; besides, if hempen netting be used and made tight, the contraction with rain will hind somewhere, perhaps to the injury of the bearing spurs of the tree.

GRAFTING BUCKLAND SWEETWATER OR DUCHESS OF BUCCLEUCH GRAPES ON LADY DOWNE'S (*A Subscriber*).—We can hardly give an opinion of the merits of these two Grapes. The *Duchess* we know to be of excellent flavour, perhaps the very best grown; but it is far from being a showy Grape, and we expect will not figure much at exhibition tables. Either of these, however, will do on *Lady Downe's*, and we should certainly prefer that stock as it is there, to removing it and planting anything else in its place. As you are anxious to multiply varieties, perhaps the stock will admit of two grafts, and then you can have both kinds. We would, however, recommend you to try *Alicante* in your late house; it promises to rival *Lady Downe's* in keeping, and is a larger bunch. Much as has been said about *Vine stocks*, it is not unlikely but it will be found out hereafter that each variety on its own roots is as good as any.

SQUIRRELS DESTROYING GOOSEBERRIES AND WALNUTS (*A Twelve-years Reader*).—We fear we have no remedy to offer to this unusual enemy. Netting, we imagine, will be ineffective with the *Gooseberries*, but it may be tried; and we have not much faith in tying gorse around the stems of the *Walnuts* if the tips of the branches reach within 6 or 8 feet of the tips of other trees to which the squirrels have access, for the nimble depredators take flying leaps a long distance. Shooting, we apprehend, is the only resource. We have often enough known rooks to carry off *Walnuts*, and of course squirrels are very fond of them, and if your garden be in the vicinity of game preserves, we expect you will suffer; but we never heard of *Gooseberries* being destroyed by squirrels before, and perhaps the publicity given to your case may induce some of our readers who have suffered in like manner to record their remedy, if they succeeded in discovering one.

PLANTS (W. R. J.).—Those you name are recently introduced. *Schizostylis coccinea* is a half-hardy bulb. *Osmanthus ilicifolius variegatus* nans, Japanese evergreen shrub, probably as hardy as the *Camellia*. *Thuopsis dolabrata* is related to the *Arbor Vite*, and quite hardy, and so is *Euonymus japonicus variegatus*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 21st.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COMPARATIVE HEALTHINESS OF DIFFERENT KINDS OF FOWLS.

It is said that a boy on the top of a Swiss mountain throws a snowball, which becomes an avalanche and destroys part of a village. In an inverse sense we cannot help thinking that

our poultry experiences may in some very small degree lead to measures that may form one of the many trifles that will eventually make the rinderpest a thing of the past, susceptible of treatment; not requiring the Draconian method of stamping out by wholesale slaughter, nor imposing restrictions that will limit our supply of meat for a long time to come.

We left off by saying, at page 279, that when the *Dutch*, from whom we imported the birds that spread illness and death everywhere, found that these birds from their diseased state when they arrived were unsaleable, they adopted precautions

that caused the birds to arrive in better condition. But people had learned their lesson. It was not enough to get fowls stronger than those they had had, but they wished to possess some that would not keep them in constant excitement as to whether the hearty, frolicsome fowls of Tuesday would not be the moping moribund things of Thursday. They found certain breeds were prone to disease, and they gave them up. Hamburgs and Polands went to the wall. These were the breeds that with very few exceptions brought contagion with them.

As we are writing on poultry, and not on the cattle plague, we must observe here, that in many parts of Yorkshire Hamburgs had been known for years as healthy birds, and remained so; but few yards introduced imported birds for the sake of fresh blood without paying the penalty in the shape of sickness. Spangled Hamburgs, or Moonies, are not included in the breeds that could be regenerated by foreign blood. They are little, if at all, known abroad. Common-sense men did not trouble themselves about causes, but accepted results. Hamburgs and Polands were subject to roup; then they would not keep them, and they gave them up. Scientific men thought they would inquire into causes. Dr. Horner, of Hull, was the first, as he was, perhaps, the most distinguished. He first said the roup was not contagious. Everybody laughed at him, but everybody was wrong. It is not contagious. You may take the roupiest fowls that were ever seen, and may put a dozen with Spanish, Brahmas, and Cochins. Not one of these will take it, or be affected by it. Not so with Hamburgs or Polands; it would almost seem that with them contact with a healthy imported Dutch fowl would produce roup, as we are told the contact with a thoroughly vaccinated European gives smallpox to the Indian. There is a predisposition.

Hamburgs in England now, without contact with foreign birds, are as healthy as any others. They are bred here and acclimatised. Something of the same may be said for the birds recently introduced from France. No one can deny the merits of the Crève Cœur and La Flèche breeds, but numbers will endorse what we write when we say that even the healthiest undergo a period of sickness, especially the cocks. It is difficult to assign a cause. We have imported them from a low damp district in France, we have put them on a dry gravelly soil with every appliance we know of that is conducive to health, and yet the cocks sicken unto death; the hens sicken and swell at the eye and face, but they, nevertheless, are rubicund, they lay and do well, and acclimatise. The same cannot be said of the Houdans. We have imported them at the same time with La Flèche and Crève Cœur. It is our duty to try experiments, and we have given them the place where they would be subject to every disadvantage, but they are veritable gallinaceous Mark Tapleys. They are always jolly. They ail nothing, and nothing ails them. They came from France together, and they have been left together; one grew worse, and the other improved in condition daily.

Our counties that are not in the first odour for high farming, and that have kept to their own stock are free from cattle disease. We have milk to drink, butter to eat, and our stalls are full of calves. They are healthy at night, and we look at them in the morning without misgivings.

Poultry fanciers are not retrograde people. Professional men swarm among them. These generally draw correct conclusions, and by their help poultry-keepers have done the same. They found certain breeds were prone to pest, and under some circumstances sure to have it. They found others never had it, either spontaneously or from contact. They have kept to the latter and eschewed the former. The result is, that which threatened to destroy poultry years ago is almost unknown now. May not the same be true of certain breeds of cattle?

RAILWAY CHARGES.

In sending you the fourth list of those who have replied in the affirmative, I may mention that several have written to me expressing their approval of the effort, but declining to do anything in the matter, believing it hopeless. I can very well understand that an individual effort to alter these charges would be hopeless, but I am not yet convinced that it is so under our present circumstances, and I trust that events may prove the contrary. I have had two or three refusals; but I have been more than astonished by one letter, containing quite a glowing eulogy of one company. This was, I suppose, to prove how badly exhibitors are treated, for our French neighbours say that "the exceptions prove the rule." Certainly it

was a shock to my nerves. However, almost by the same post came a letter from one of the largest and most successful exhibitors in Yorkshire, in which he said he had shown 239 pens during the past year, but only sent 63 pens by rail, the cost by this conveyance being so enormous! Surely this is a case that speaks volumes. In a month or six weeks I propose to send you the last list. I have therefore to ask all who feel interested in the matter to communicate with me. Many have not replied at all. As regards the signing the requisition, it is not necessary that a subscription in money should be made in every case. The railway companies will know nothing of these amounts. They are simply published in the columns of "our Journal" as a kind of acknowledgment. If any who have written to me feel themselves aggrieved at not receiving replies I must beg their kind indulgence, as my spare time is taken up in communicating with other exhibitors.—JOSEPH HISTON (Y. B. A. Z.), *Hinton, near Bath.*

THE DISQUALIFIED PEN AT WIGTON POULTRY SHOW.

No one can be more sorry than myself that the letter from Mr. A. K. Wood, of Burnside, Kendal, inserted in your last week's Journal, should necessitate still further observation respecting the "disqualified" pen of Silver-spangled Hamburgs at the late Wigton Show. As, however, this gentleman's letter conveys, by the most direct inference, to the minds of those of your readers who are unacquainted with the actual antecedents of this particular bird, that the hen's comb was beforetime firmly set on the head and upright, it becomes my imperative duty, in correction, to reply.

As the owner openly assures us he is "entirely ignorant of how the needle got into, or who put it into the comb, as those who saw it pulled out, and that he is prepared to make an affidavit to that effect"—I beg to assure Mr. Wood (though personally unknown), the latter course is entirely unnecessary, for I am quite ready to give full credit to his personal assurance alone; whilst to my mind affidavits in such cases are altogether misplaced. After stating "he is perfectly certain she was not trimmed in any way for the [Wigton] Show," Mr. Wood proceeds thus: "How long the needle had been in the comb to me is, therefore, a problem I am unable to solve. I am sorry to see your reporter's concluding remark, as it seems to hint that it had been put to keep her comb straight. I have repeatedly been to see her since this, to me, unpleasant affair has happened, and I confess I cannot see that her comb droops on any side, and I scarcely think the Judge would deny that the pen was the best, even after the needle was withdrawn. Do not mistake me: I do not complain of losing the prize under the circumstances, as, of course, the Judge and Committee would not be aware of my ignorance of the needle's presence." As to the probability of the needle being imbedded in the comb by accident, the fact is such an occurrence amounts to a sheer impossibility, as any one may individually test by endeavouring to force a needle lengthwise into the comb of any fowl already killed for the table. The comb's substance, being rather cartilage than muscle, offers a very considerable resistance to such an impalement, and the excruciating agony produced if the attempt were made on a living fowl could only augment the difficulty. I find that though the extracted needle appeared to unassisted vision (as was described in your report) "broken off abruptly at the eye," by the additional aid of a very powerful microscope in my possession, it evidently proves to have been not broken off at all, but nipped off with a pair of very sharp-cutting pincers. This renders the probability of mischance more remote than ever. As an arbitrator, if certainly in no way devolves on myself, as a duty, to seek out the actual transgressor, but simply to unreservedly expose the deception practised. Still, as Mr. Wood declares himself "unable to solve the problem of how long the needle had been

in the comb of his hen," a few general items may tend to aid him in his investigation. On January the 15th last, this cruelly ill-used fowl was shown with another equally good hen in all points at the Walsall Poultry Show. The second hen was perfect in comb, but the one in question had her comb loosely hanging on one side, and for this sole reason I only "highly commended" them. Almost immediately after the decisions were made public at Walsall, a very angry and hotly-worded telegram from Mr. Wood demanded the fowls' "immediate return by the next train," with a very abrupt comment on my decision of a high commendation only, that certainly here needs not repetition. From Mr. Wood's present letter, this telegram seems to have slipped from his memory altogether. Of course the Committee did not comply with the request.

After the receipt of the telegram, and before leaving the committee-room, I answered the inquiry of the gentlemen present by at once referring them to my award-book, and opposite the number of this pen was the pencil note made by myself whilst judging—"hen's comb over." As after the receipt also from Mr. Wood of a very angry letter to the Walsall Committee, and again another of like nature to myself, it was suggested by some one else present "It would be well to be able to give conclusive proof of the individual identity of this particular hen in case of any prolongation of the dispute"—I myself placed a private mark on one of her feathers; but nothing farther after that time transpired. At Wigton, after the discovery and extraction of the needle, I at once looked for this feather, marked by myself at Walsall, plucked it out, placed it in an envelope, and it remains still in my hands. I have permitted the needle to be inspected by two medical friends, whose joint opinion it is, "judging from the corrosion of the needle alone, without seeing the bird itself when suffering, it might possibly have been imbedded in the comb some few weeks, or even months, and that though Nature was attempting the removal of this foreign substance by a process closely approximating to the exfoliation of a splintered bone, it would most probably, if unaided, have taken even yet a considerable time to work out a thorough cure." Any one, therefore, who has suffered from a thorn in the flesh only can give a very faint guess of the suffering endured by this poor hen prior to the extraction of the needle.

Mr. Wood suggests the question, "That he scarcely thinks the Judge himself would deny that the pen was the best, even after the needle was withdrawn." I am decidedly of that opinion, and will even also add, that I firmly believe that Mr. Wood has the best pair of Silver-spangled Hamburg hens in England, if the comb of this one hen should now remain as "free from drooping on any side," as represented in his present letter. Time, I fear, will prove this not to be the case; the comb's ultimate uprightness, being, to my notions, extremely problematical.

In conclusion, I did not myself at Wigton (where she was shown singly), recognise this from the fellow hen that with her I have so frequently seen at other poultry shows, for her comb being erect, I passed her with first honours, as no doubt, most unwittingly, I have many other deceptions of a like character (perhaps far more than I conceive), from different exhibitors at a variety of meetings.

It is in my opinion, however, the fixed duty of any public arbitrator, when deceptions are in the first instance detected, or afterwards revealed, as in this case, from information received, to visit the offence with open exposure of the affair, and immediate "disqualification," carrying out the unvarying rule indifferently to all alike.—EDWARD HEWITT, *Sparkbrook, Birmingham*.

NOTES ON PIGEONS.—No. 3.

FORMER ENGLISH WRITERS ON THE SUBJECT.

"THE TREATISE" OF A.D. 1765.

AFTER John Moore's "Columbarium," published, we must remember, in 1735, there was, as far as I can learn, a pause in regard to the issue of works on fancy Pigeons. I follow the idea that the book did not sell, or that few copies were printed, and that, as with the works of many disappointed authors, certain copies were destroyed in the writer's own house in a fit of disgust. People do not like to be reminded of a failure; and a whole bookcaseful of an unsold edition (I once saw such a bookcaseful in an old clergyman's house, whose wife had in an unfortunate hour written two volumes of terrible trash on the Church catechism)—must be a painful reminder. Be it as it may, Moore's work is a marvellously scarce book now; but

so good a book must have been prized by genuine Pigeon-fanciers; it must have been welcomed by such, and pored over many a winter's evening by the fireside. But think of what England was in 1735. George II., of uninteresting memory, was on the throne. Walpole—every-man-has-his-price Walpole—was bribing all round. The state of manners and morals was deplorably low. Gaming was the vice of the age. Gentlemen gambled at their clubs, ladies in their drawing-rooms, and it was no unusual thing to lose or win £10,000 in a night at cards or dice. Within ten miles of where I am writing an estate of great value came into the hands of the noble family who now possess it as a stake won at cards, and its total value then was less than its yearly rental now. If such was life in the higher classes, we may be sure that the lower were good imitators. At any rate, it was a time when the taste was low, and pure home pleasures not much cared for—when there was little love of poultry, though great love for fighting cocks. But much was against the circulation of any book written upon what always has been, and always will be, but the hobby of a minority: thus, each county was more isolated from other counties than the whole country now is from France; books travelled down into the provinces very slowly; these were the days of slow coaches and bad roads, when a wooden-legged man, being offered a ride by the coachman, declined, saying, "No, thank'ee; the fact is, I'm in a hurry, and so must walk." Hence, to come down to our subject, Moore's book would have, I fear, few readers out of London. I can, however, well imagine the delight of, we will say, some Yorkshire fancier (Yorkshire always has been foremost in these things), upon receiving from a town friend and brother fancier—some cousin gone to seek his fortune—a copy of Moore's "Columbarium." But yet in these days each man with a hobby had, as a rule, to depend on his own immediate neighbourhood for supplying him with friends having a fellow feeling, as means of communication were so difficult. Hence it was that breeds of fowls remained in certain counties and localities; thus I have heard old people belonging to Lincolnshire tell of zealous Game breeders riding with their favourite birds carried on their saddles; but these, of course, would be short journeys.

How many or how few readers old Moore found, he found one who admired and approved his work so heartily, that he reproduced nearly the whole book. This was the author of "A Treatise on Domestic Pigeons," printed and sold by C. Barry, Fenchurch Street, London, in 1765, just thirty years after the publication of the "Columbarium." I have a first edition lying before me as I write. Strong and very dark with age is the old calf binding, and yellow the substantial leaves. It is by no means closely printed, but contains only 144 pages; but we must add to them sixteen pages of preface. It must be noticed that the writer does not give his name; but he dedicated his work, or rather compilation, to one John Mayor, Esq. In a very lengthy title-page the writer tells us his work was "carefully compiled from the best authors." The plural might almost have been spared, as it is chiefly from Moore, and very frequently even word after word. There was one great addition, however, of which the lengthy title-page informs us in these high-sounding expressions, "Illustrated with a frontispiece, and cuts elegantly and accurately engraved from life by the most able and eminent artists, under the immediate inspection of very experienced fanciers." Moore had deplored the want of illustrations. He says "I am very sensible that proper icons [a queer word for pictures] are of very great service to illustrate a work of this nature; but this piece being in its kind new, and not being able to guess at what reception it may meet with from the world, I knew the expenses of exact cuts would swell the price too high for many that may have a mind to purchase this work; and on the contrary, that if they are not delineated with the utmost accuracy according to their various characteristics, they only puzzle the mind, and render the description of them more obscure; and therefore I choose rather to have none than bad ones." Wise John Moore! But the author of the "Treatise" evidently knew the value of pictures had or good, and wished his book to catch the eye as well as please the mind.

The "icons" of the "Treatise" are thirteen in number, and I cannot say much in their favour. First, the frontispiece presents us with a portion, I presume, of the interior of a loft. On the floor is the hopper, on which stands a Pigeon meant to be an Almond Tumbler. In front of the hopper stands a mouse in a supplicating attitude, while a skinny cat is pretending to look at the water-bottle (an inverted carboy), to her right, while of course she intends to catch the supplicating

mouse on her left. Did mice pray for their lives in the early days of the reign of George III.? or did they, as now, run away at the sight of a cat? In a dark recess stands an egg-basket with two eggs in it, set on a piece of stone, the whole looking very like one of those birds'-nests you see as ornaments on a college mantel-piece. Something like a couple of rabbit-hutches hang up high on the wall, and a landing-net hangs on the end of the hutches. The doors of the hutches are closed.

In regard to the other "icons," we have an Almond Tumbler that would not most certainly take a prize in these days; a Mottle that any fancier would kill at once, being painfully light-coloured; then comes a Carrier shaped like the little birds one's children cut in paper with a pair of scissors. A dumpy Fowler follows, being fearfully thick in the waist; a Leghorn Runt intensely ugly; and then come a charming Jacobin, which gives relief to the eye; a Nun, none of the handsomest, an Owl better-looking, and a Turbit very so-so. Then a Fantail robbed of its gracefulness, a shameful robbery indeed; a Trumpeter exceedingly like the Mottle, with tiny tuff and top-knot, and o'er-short boots; next a fair Barb, and finally a Lacey. Unlike Henry VIII.'s Flanders mare, fancy Pigeons even in the time of the "Treatise" were much better-looking than their portraits, or few people indeed would have kept them.

The "Treatise" passed, I imagine, into the hands of many, as it is constantly quoted with or without acknowledgment by succeeding writers. The book ought to have been called "A Second Edition of the Columbarium, with Additions." Thus we have in it the first mention of the Bald-pated Tumbler and the Beard, and of the beautiful Black and Yellow Mottles; also the Lacey and Frillback are described for the first time. Then we have here and there an additional bit of description, as in the fuller account of the Owl; then a practical remark, as in the case of the Leghorn Runt, drawn from the writer's own experience. Although the compiler of the "Treatise" did not act quite fairly to old Moore, yet his compilation did much good. The pictures—and our forefathers were not hard to please—helped to bring the book into notice. Young people, attracted by the cuts, not being severe critics, would cease to be allowed to keep fancy Pigeons, and "Love me once love me always" might be the motto of these charming birds. Then there are four booksellers' names attached to the book—four interested in its sale; and so the "Treatise" made its way, and made Pigeon-fancying more and more popular. Hence let us give a word of praise to its compiler, though his name we know not and never shall know.—WILTSHIRE RECTOR.

BURYING A HIVE.

In the autumn of last year a cottager in this locality, after having brought his hives from the heather, found one of them very light, and it was daily becoming more so, in consequence of the bees in his other hives having made an attack upon it, and they seemed likely very soon to complete their work of spoliation. The owner, after trying several plans to keep off the marauders, but without success, saw no chance of saving the colony from the lawless attacks of their neighbours, except by entire separation from them. The following is the method he took to effect this, regardless of results.

A pit was dug in the ground; into this the hive, floor-board and all, was put, then packed round, or in a manner thatched over with straw to the depth of several inches; over the straw was placed the soil, around and above, forming when finished a small mound. The hive was, in short, literally buried, with no apparent means of air gaining admission. It was buried on the 8th of November, and exhumed on the 12th of March, having been fully four months in its subterranean home. On lifting it out, to the owner's surprise as well as delight, he found the inmates lively and well, and on examination could find no traces of their numbers having diminished. They are still very active and working well, bidding fair to rival their more favoured neighbours and once implacable enemies. I am sorry I cannot give the weight of the hive when buried, nor when exhumed, but the sensible decrease was very little.

I am not aware whether this plan has been much practised or not, or whether it is consistent with the natural habits of the bee. The only other similar instance of which I have heard was that of a hive left on the hills in autumn, and which in early winter was encased in snow, and remained so till late in spring. It worked well all the season, and at the close rewarded the owner with a large quantity of honey. Would not this plan of hurrying in the winter be admissible with weak and light stocks? The darkness and cold would induce a greater

degree of dormancy in the insects.—J. A., *Whittingham Gardens, Haddingtonshire.*

The successful result of this experiment was doubtless owing to the straw packing, which protected the hive from moisture and insured sufficient ventilation. A similar method of avoiding the intense cold of the winter is sometimes resorted to in Germany, and, we believe, also in America; but it is generally deemed more advisable to deposit the bees in a dark cellar or outbuilding adapted for the purpose, instead of resorting to actual interment.

OUR LETTER BOX.

CAYUGA DUCKS (*H. C. P. G.*).—All that we know about them is contained, with a drawing of them, in the "Poultry-Keeper's Manual," published at our office, price 7s. 6d. We do not think that they have been introduced into this country.

INCUBATOR (*Mrs. Gifford*).—We published what we were told by a reliable authority, but, as we have heard no more upon the subject, we conclude it has failed. Brindley's we have seen and should employ if we required one.

HENS WITH SWOLLEN ABDOMENS (*S. S. Woodlands*).—The swollen, shiny, red abdomens, accompanied by thirst, demonstrate that their egg-systems are very much inflamed. They are fed too liberally and kept too warm. Give each a dessert-spoonful of castor oil, no corn, but boiled potatoes mashed up with a little barley-meal, a pill containing one grain of calomel and one-twelfth of a grain of tartar emetic, three times with intervals of a day. Give abundance of green food, especially lettuce and grass.

FOWLS DYING STUPIDLY (*W. H. W.*).—"Suddenly dropping down dead" is too indefinite a description. If they had previous twitchings of the head, or fell, or were giddy, death arose from apoplexy, a blood-vessel of the brain having given way. This usually arises from the birds being too fat. A dessert-spoonful of castor oil and a low diet, such as boiled potatoes with a little barley-meal, no hard corn or animal food, but plenty of grass and lettuce leaves.

VARIETIES (*Nathn*).—The cross you mention (Cochin and Chitteprat), would hardly produce a good sitting hen, and we are not surprised she left her eggs. The symptoms you mention are those of gapes, but adult fowls are not subject to them. We should therefore believe she has a cold. This would cause mucus in the throat, and the action you speak of is caused by the desire to get rid of it. Your friends' chickens die of gapes. Small pills of camphor, and camphor in their water, will cure them.

FOWLS BREATHING WITH DIFFICULTY (*A. F. N.*).—Your fowls are only suffering from cold and damp weather. Dry days and warm nights will cure them. You will find benefit by giving them occasionally a pill of camphor the size of a pea, and by putting some in their water. (A. Y. Z.)—The treatment recommended above, with the addition of bread and ale, will suit your case. Keep them on the driest spot you have. The pill of camphor for a chicken should be about the third of a pea, and their water should be strongly impregnated with it.

FOOD FOR FOWLS (*Harris*).—There is always a difficulty in naming a proper quantity of food, unless the nature of the run is fully known. One yields three times as much natural food as the other. Six large fowls will consume more than a breakfastful of corn in a morning if their run affords them nothing. Your middy meal is a sorry one. There is little support and no health in potato peelings. The little good in this food is from the meal. Give them the cupful of meal slaked with water, and minus the peelings. Feed your young chickens on chopped egg, bread and milk, crumbs, table scraps cut very fine, bruised wheat, and give them beer to drink. Your feed is neither good enough nor sufficient. At the same time we can lay down no rule for you, you must draw your own conclusions. Feed them in the morning so long as they will run after and appear anxious about the food; when they become listless give no more. Follow the same rule midday and evening. They will eat more at first than they will afterwards, because they are in low condition. Afterwards, they will eat less, but you will always find some irregularity in quantity. You must not let them have food by them. Nature at this time of year teams with food on the surface of the earth where it is grass land. When they have had enough from your hand they will spread over the ground, and find a hundred things we cannot perceive, but that are all beneficial to them. Let your chickens have the run, but keep the hen under the rip till they are two months old. Let them have dust or ashes to hask in. If you follow these rules you will rear all your chickens.

DUCKS NOT LAYING, AND CASTING THEIR FEATHERS (*Ruth*).—Your Ducks are poorly fed. Potato peelings and Indian corn are not good enough. Give them whole oats, and for a time they will want plenty of them. If you do this you may add the kitchen scraps, and they will do well. The casting of perished feathers at this season of the year in poultry is like the moult in animals—a sign of bad and low condition, arising generally from being fed in quantity with that which lacks quality, or from lacking something Nature demands. Your Ducks have plenty of exercise, but, like Oliver Twist at meal times, they ask for more. Give it in the shape of oats, and it will expedite their recovery and their laying if you feed them first in a milkpan. Put a large sod of growing grass at the bottom, then put a layer of oats, and cover the whole with water. Eschew potato peelings: the whole root is poor food; but when you give only the refuse it tends to poverty, the plumage perishes, and eggs are desiderata.

EGGS NOT HATCHING (*G. M. F.*).—The heat in your incubator at some time went down too low. Life was generated, but it was allowed to perish. There are no means of ascertaining the fitness of eggs for sitting; but you can ascertain at the end of four or five days whether the process of hatching is going on satisfactorily.

GOATS (*S. E.*).—As the period of gestation is five months, kids might be produced twice in the year, but it would weaken the mother. She continues to breed until six or seven years old.

REMOVING BEES BY RAILWAY (*J. Collins*).—The great risk of removing bees in June or July arises from the probable heat of the weather. If, however, you can choose a cool day (night would perhaps be still better), and contrive to give plenty of air by tying the hive up in a cloth of open texture, such as cheesecloth, we should think that under your own charge they might travel safely.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 61.7°; and its night temperature 39.3°. The greatest heat was 84°, on the 6th, 1862; and the lowest cold 20°, on the 2nd, 1855. The greatest fall of rain was 1.26 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

SEEDS, AND WHAT TO DO WITH THEM.—No. 1.

WIDE subject is this, and one of sufficient importance to write a volume upon if full justice had to be done to everything; but the object of the present paper is merely

to offer some remarks on the seeds which most commonly come before us, and such as claim special notice either from their character or the peculiar conditions necessary to insure their germination. Commencing with the Grasses, let us examine them before we determine on the mode of committing their seeds to the ground.

Grasses are amongst the most useful and widely distributed of all the families of plants, affording food to both man and the most valuable animals; and as they produce seeds in abundance, the multiplication of an individual species when wanted is only difficult or otherwise according to the skill used in cultivation. As treatise after treatise has been written on the culture of such cereals as we depend on for our sustenance, the conditions under which the more common Grasses are generally met with need only be glanced at, in order to see how far these conditions agree with the mode of cultivation which we adopt when we want to increase the number of any particular species. Grasses, it is well known, produce seeds in great abundance, which ripen about the time that the hay crop is cut, or rather later, for it is seldom allowed to remain uncut until the Grass seeds are ripe. The seeds remain a longer period attached to the husk or stem that supports them than those of many other plants; eventually, however, they are shed, and the chances are very remote of their falling upon such a prepared seed-bed as is often made for them when they are sown artificially. Most commonly the seeds fall by the side of the plant, and if this is growing in a pasture field the ground is dry, hard, and already occupied with Grass; or if by the side of a road, the place is often as hard as a macadamised turnpike. Neither of these conditions, however, prevents the seed vegetating when the proper time arrives, which is usually September, after the early autumn rains have soaked the seed, and given it that impulse which it follows up; hence we have the best possible time pointed out to us by Nature for making a permanent sward, and by sowing the seeds in the last week in August or first in September the best results are likely to follow. If any one be sceptical on this point, let him only notice the innumerable plants of Grass that will often make their appearance in the early autumn months in walks and other hard places not too much trodden upon. The progress of such little plants is certainly not rapid at this time, but they survive the winter, and are ready to start into growth early in spring; in fact, if the

winter is mild, they never cease growing. If, instead of sowing Grass seeds in autumn, they be sown in spring, the result will not be so satisfactory; for, though a great many will grow, the proportion will not be nearly so large as when they are sown at the time which Nature points out—viz., early in autumn.

Many seeds possess a coating of some substance designed to protect them whilst in an inert state, from the time they become detached from the plant until they commence to vegetate. Gum, oil, and resin form a covering to a large number of seeds, and these substances preserve the seed until it is required to grow; for, unlike the Grasses, many of the seeds so protected require a considerable time to undergo the changes that occur before germination fairly commences. Some remain in the ground a considerable time, while others swell and commence growing very soon after being committed to the ground. Of the latter, those cases over with an oily substance seem to germinate soonest, as in the Cabbage tribe and its allies; resinous seeds, as those of the Coniferae, require more time, contact with mother earth in their case not effecting the change so speedily as with those previously mentioned; but it is accomplished, the agencies at work in the soil being generally sufficient to free the young plant from its resinous covering. I may here remark that there is every likelihood that the soil best adapted to the growth of a plant is also that best calculated to insure the proper germination of the seed; for such soils, doubtless, offer the natural conditions most favourable to such a result being brought about in the shortest space of time. Seeds of leguminous plants present great diversity, some of them having but little external covering to hinder germination, while others—some Australian seeds, for instance—are cased in an armour of gum, which requires more than ordinary artificial help to enable the embryo plant to make its appearance. Such seeds are therefore often soaked in warm water, which removes a great part of the gum, and leaves the remainder so reduced as to allow the plant access to the outer world. The artificial means here advised ought not to be resorted to if it can be dispensed with, as it is an operation not intended by Nature, but merely one artificial process adopted to correct another, these seeds being of foreign not indigenous growth, and having been brought many thousands of miles under conditions never occurring in nature. In consequence of this the gummy substance hardens into a sort of case, impenetrable to the influences at work in the soil in an ordinary state; hence the necessity of using extraordinary means.

Besides the above there are many other ways in which seeds are preserved until the proper time for their germination. Some seeds are embedded in a pulpy substance destined to protect them until the proper period for the commencement of growth arrives, and of such Gooseberries, Currants, Strawberries, Tomatoes, &c., afford examples. Seeds of this character should always be preserved when practicable with the pulp adhering, as they are deprived of the most important part of their keeping qualities when it is removed. This section embraces many kinds of plants in general use, and which are often propagated by other

means than by seed. Some seeds remain for a long time attached to the plant that produces them, and some, though cast off, are still found in numbers enclosed in a sheath, capsule, pod, or other covering, from which they are liberated when the proper season arrives. I will not, however, follow this subject further, but will now make a few remarks on another feature peculiar to some seeds.

The modes in which the seeds of plants are disseminated are not less various and wonderful than the means for their preservation. Some seeds are armed with a thorny substance, rendering them formidable to the birds or animals that would otherwise consume them; some are also rendered capable of being transported to long distances, either by their extreme lightness or by being furnished with a sort of substitute for wings, as in the case of the common Thistle, which floats in the air to long distances; others attach themselves to animals, as the seed of the Goose Grass, and may thus be carried a long way off; while others, again, are contained in a sort of pod, out of which they are jerked at the proper time to a considerable distance, as with the Balsam, Laburnum, and Pellitory of the wall. The dispersion of seeds is likewise effected by birds and animals congregating at the place where they are produced; thus a bird carries off a Cherry to some distant tree, eats the pulp, and drops the stone. In addition to those glanced at, many other natural modes of transit are met with.

We now come to the conditions necessary to insure a long continuance of vitality in seeds. Ground has been turned up which there is every reason to believe has not been disturbed for a century, and perhaps plants spring up in it without having been sown there, leading to the inference that they had been deposited there at some time, and, being excluded from the air, could not germinate, but still were able to withstand the decaying influences of the medium surrounding them. Seeds buried by the spade or plough very often appear after a year or two, but as to whether it is true or not that certain seeds have preserved their vitality for such long periods as they are sometimes asserted to have done, I will not hazard an opinion; and there is some doubt whether those seeds yielded by the mummy caverns in Upper Egypt were really as ancient as the mummies themselves.

I now come to the important subject of how to treat seeds which we wish to turn to account, or rather in what way we are to preserve and sow them so as to insure a successful result. The latter is a question of sufficient importance to demand a separate paper, and the former has been in some degree treated on in the remarks made on the natural means by which seeds are preserved; and if we follow as far as we can the rules of Nature we cannot very well err. Some departure from them must of course be made, but let such be as little as possible, and the result will most likely be successful. These remarks, however, relate only to the preservation of seeds, which, as objects of commerce, too often are subjected to processes calculated to please the eye rather than promote germination; but the sooner that the latter become the paramount consideration the better. As the subject of sowing seeds deserves more space than can be given in a single article, it must be deferred till another time.—J. ROSSON.

BLEEDING OF VINES.

If a Vine shoot bleeds from the wound made by the knife in pruning, if the cut has not been so made, let it be made so as to leave an inch or two of stem above the bud. Cut clean in a slanting direction as in ordinary pruning; then take a Potato, and, cutting off a slice, press the Potato carefully upon the shoot, so that the Potato may not split, but completely cover the wound. The Vine will not afterwards bleed for more than a few hours at the most. The sap of the Vine and juice of the Potato seem to form a sort of starchy compound effectually stopping up the pores of the shoot. The Potato must not be removed until the leaves are growing vigorously, and, therefore, elaborating the sap.

I have tried this remedy for the last two seasons, in both cases having had my Vines pruned too late, and sometimes have had the half of a Potato on every third spur, and I have never known it fail. This year I cut down, about a fortnight ago, young canes that were just breaking to within a few eyes of the base, applied the Potato at once, and in none of the three cases has any bleeding whatever occurred.—CONSTANT READER, *Lincoln*.

P.S.—The Potato should only be cut at the part at which

the shoot is inserted. It would not do to use merely the middle part of the Potato with both ends cut; at least, I have only tried it as I describe.

MY NEW ORCHARD-HOUSE.

The winter, now happily past, has been a remarkable one, if only for its high temperature and destructive storms. The Channel Islands, situated as they are in a large bay, the form of which greatly influences the tidal wave, and lying at the extreme edge of the vast European continent, while the open Atlantic encircles their rocky shores, have experienced their full share of the dangerous winter gales.

Guernsey, as the outlying island of the group, of medium size and elevation, is peculiarly disposed to develop the pernicious influences of contending land and sea aerial currents, which, in their action on each other, tend to produce rotatory storms of a destructive character. That of the 11th of January was of this nature, and did considerable damage to the island in consequence. It will, no doubt, be of interest to the readers of this Journal if I describe some of its effects, and note chiefly the dangers which the numerous vineries in the island underwent, and especially my own houses. These dangers arose mainly from the cyclonic character of this awful storm. This consideration leads me to hope that some of the intelligent writers in this Journal will devote more of the fruits of their experience for our benefit in such very important matters as the ability of wood and glass to resist storms with a pressure of more than 28 lbs. per square foot—that is to say, when the pressure reaches 30 lbs. per square foot during frequent squalls (of tolerably long duration too), that the danger to which glass houses of the ordinary construction are exposed must be enormous. If this happen, then, during a rotatory storm, which tries all parts of the houses in succession, it is evident that we require all the appliances of science to preserve them. I doubt, therefore, if a large span-roofed house would have weathered the gale of the 11th of January during the period when the house received the fullest force of the air current on its broadside. In such houses, therefore, we must mainly rely on extra solidity of construction, joined to the advantages of a naturally well sheltered position. On this, and on other points, however, experience and mechanical skill may best decide.

Living, as I do, in an island, which my friend Professor Ansted in his "Channel Islands" describes as the battle field of all the blasts under heaven, and having had one large orchard-house completely destroyed in a gale in 1860, and the new house just added much injured on the 11th of January, these matters are of importance. Mr. Clay, of Hampton Court, writes to me that his large house was several times flooded by the Thames. This, by loosening the foundations, could it have occurred with us, might have caused the destruction of all the buildings in even an ordinary gale.

To understand, then, our risk, let me briefly describe the situation of our houses, now seven in number. By the addition of the new orchard-house, which is a lean-to like all the others, the whole now present three sides of a square, which I consider to be a form well calculated to resist ordinary gales from the usual quarters. The fourth side (of shrubbery), being on the quarter least exposed to damage, allows the current of air to escape freely. We are thus only subject to injury from the east, which, however, would be unsafe in many other places. To the south and south-west, to the west and north-west, all points whence proceed customary gales, we present either the strong back walls of lean-to houses, or else, as in the case of the new house, a front of glass framed in rafters of extra strength, with thick stone walls for gables, and a high back wall, at least 18 inches thick, which also protects the upper side of the square. We are sheltered naturally by an adjacent hill, the elevation of which, however, at times causes a plunging current, which those who live in valleys know to be dangerous; but the square is adapted to meet this, and the open side is invaluable. The effects of this cold evaporating current on vegetation are painfully perceptible. To the north and north-east we show only solid walls, and the dwelling-house itself, continuing this side of the square, materially protects it.

The strength of glass used is generally 18 ozs., most of which comes from Belgium. The sizes vary from the largest sizes in the old houses to much smaller in the new house, which is most exposed. We experienced, however, during the

whole winter a variety of gales; one of these, with a pressure of about 24 lbs., from the south-east, broke panes of small glass in the hothouse, while those of 26 inches by 22 in close proximity were uninjured; but they were in much peril, and we were obliged to introduce soft substances, such as rags, between the edges, as the elasticity of the rafters was too great. Another violent storm, not of a rotatory character, from the south-west broke a number of the small panes of glass framed in solid rafters, and left the large panes uninjured. The squalls of this storm were frightful, and reached a pressure of 28 lbs. per square foot, damaging the roof of the dwelling-house, and levelling many fine trees. At other times, many large-sized panes in the old orchard-house were broken along the upper ridge, while none of the lower was injured. This was by the direct action of the ground current. Again: at other times, when the wind struck the back walls it leapt over them, and, penetrating under the edges of the large panes, broke them by rattling them together. Much glass is lost in this manner, and it would be well to have the glass of the upper part and of the extreme ends of greater thickness. On the whole my experience tends to this, that the largest panes are safe if the glass be of 21 ozs., and the rafters not too elastic. There can be no doubt as to the appearance and orchard-house look produced by the use of such large-sized glass. It must, however, be carefully laid on, and the edges should fit accurately.

The storm of the 11th of January was in this wise. It blew continuously, as, indeed, it does in this island generally, from the Sunday night to the Wednesday afternoon, previous to the fatal Thursday. The wind oscillated wildly during this period from south-west to north-west. It then fell calm for four hours, the aerial current backing to the south-east. At night, however, a circling storm from south-west to north-east true reached us finally from the south-east. This was an exposed quarter for me, but the pressure was only very moderate, being 12 lbs. per square foot, or a velocity of forty-nine miles an hour. Then, about midnight, a sudden lull fell on the island for two hours. During this period the vortex of the cyclone passed over us. The clouds at this time presented a menacing appearance—heavy and black cumuli, hard-edged and rolled up in unshapely masses of dense and confused vapour, while from their bases a drenching torrent of cold rain fell. In one hour a rainfall of 1 inch was registered. The effects of this were disastrous; the ground became soddened, banks were undermined, and trees lost their hold on the subsoil. The barometer fell to 28.41 inches, an almost unprecedented reading; at any rate here we only know of one resembling it, on December 25th, 1821.

About 9 A.M. on the 11th the wind veered from the east to the north-east with startling suddenness, and the inner whirl of the cyclone passed over the island, somewhat partially. In a few minutes the velocity rose to forty-three miles an hour; by noon it was sixty-five miles, equal to a pressure of 21 lbs. per square foot, according to Ostler's self-registering anemometer; and, during the numerous squalls, it reached seventy-two miles, or 26 lbs. of pressure. From 1 P.M. to 2 P.M. the storm was fearful, and the pressure per square foot increased steadily to 28 lbs., with more violence in squalls.

The damage done to trees was universal. Many buildings suffered, and, but for the fact that the storm reached us when at its worst from the north-east, a point on which all the vineries in Guernsey, being lean-to's, were best defended by their back walls, the damage must have been great. As it was, one large vinery was blown bodily away from its wall. The shifting nature of the storm added materially to its dangerous character, as most of the houses had one or more weak sides. They are, however, generally very strongly built, and placed in sheltered localities whenever possible, and there are no span-roofed houses except of small size.

We were fully employed all day in securing the houses, much glass having cracked by the vibration of the structures, and slipped down. Thin planks are always in readiness to nail under any broken pane, which, with hay stuffed between, effectually secure the houses. Warned, however, by these experiences, I am dividing the houses by glass partitions, so that if any were damaged during a gale at night the other divisions might not suffer. Large branches of trees were blown across the houses into the open square, and a huge tree narrowly missed falling on the houses, being caught in the fork of another tree. A row of trees which somewhat shaded the new house had been topped, which saved them and it. The high bank, however, on which the new portion stands gave way, together with palings

and trees, and slipped down bodily about 20 feet. With the assistance of numerous workmen, obtained fortunately, the house was shored up and secured with large beams. Cracks in the green mortar threatened instant destruction, and the work, during the roar of the storm, was not done without some risk, and had to be speedily executed. The expenses incurred in under-pinning this house have since been great.

In the grounds many fine old trees were levelled, especially some *Quercus ilex* about seventy years old. These trees flourish well in the island, where the sea-blast dwarfs most of our timber. Had my state of mind been capable of relishing a joke at that period, it might have been found in the country people returning home, sitting obstinately in their carts until the public way was cleared, and steadily refusing to take any other road, vowing all manner of legal penalties. To see them thus, the women especially, wearing the ill-chosen national dress of dingy crape, and clearly demonstrating to us how wrongly we were acting in thus blocking up the highway with fallen timber "twixt the wind and their nobility," was indeed a curious sight. On a subsequent occasion a litigious farmer actually unloaded a large cart of hay which could not pass freely under the beams placed to shore up the orchard-house, sooner than take another path close by. Failing in persuading us to remove the obstacles (there being some risk, of course), he deliberately unloaded his cart and then he actually lodged an information against me. Numerous grave authorities were invited to inquire into this matter. They did so, but the obstacle was already gone! A Fir tree which we tried to preserve contributed also some mistimed hilarity; for about twenty of the good neighbours having "tailed on" to a ponderous tackle, under the guidance of a much-flogged old man-of-war's man, the rope of course yielded, and I cannot say how many gallant officers, clergymen, and medical men were prostrated amidst the applause of numerous juveniles. The tree, however, was saved, but we can always observe that carriages quicken their pace when they pass under it.

This was our experience of what a rotatory storm can do. The pressure, at times, was greater than that of 28 lbs., nearer 30 lbs. in fact. The mean temperature was 41°, never lower than 40° and never higher than 42°. This was a remarkably high temperature even during an exceptionally mild winter. Geraniums and other plants have not suffered at all. We had frost only during a few nights, and the thermometer in the new orchard-house has never registered lower at night than 40°. It was also from 6° to 8° above the outward air. What an advantage if others would also record the lowest night temperature during the winter. I must, however, defer this portion of the matter, and other changes introduced in training in the new house, for a future paper.

On the more immediate part of the subject—the right situation with respect to natural shelter for orchard-houses, their disposition with respect to protecting each other, their size and form, the dimensions of the glass and its arrangement, the strength and proper elasticity of the rafters—all these and many kindred questions seem to me to be of the utmost importance in orchard-house matters.

We have made a very fair start, and I am, for one, surprised that panes of glass 26 inches by 22 should resist gales of 28 lbs. of pressure per square foot as well as panes of the ordinary greenhouse size. They should, however, be of 21-oz. glass, and overlap with the greatest accuracy.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

WARNING TO TOBACCO-GROWERS.

I HAVE had the supervisor of excise to take account of my tobacco. The Revenue authorities seem alarmed at my growing so much, and thought I must be manufacturing it for sale. I told the supervisor that I had none on hand at present. He wanted to know how much seed I had left. I told him I had 1 cwt. including stems and all. I suppose we shall have a duty on home-grown tobacco next. I, for one, shall decline growing it then. I grow it as much for ornamentation as anything, admiring, as I do, its *Begonia*-like flower.—LACHENALIA.

CRYSTAL PALACE.—The thirteenth season, commencing on May-day, opens with great promise. Among other attractions the great Flower Show of the season will be held under the most favourable auspices on Saturday, the 12th of May. As a feature of additional interest, and to afford additional accommodation,

the beautiful gardens of Rockhills, adjoining the Palace, and the residence of the late Sir Joseph Paxton, will be thrown open to visitors. As in front of the surrounding verandah there is growing one of the largest trees of *Wistaria sinensis* in the country, and as at the time of this great Show it will be in full beauty, such an opportunity affords additional interest to the great Show of the coming season. These gardens will be again thrown open on the day of the great Rose Show, Saturday, June 23rd.

THE MANETTI STOCK FOR ROSES.

The constant accession of new readers to THE JOURNAL OF HORTICULTURE renders it necessary to revert occasionally to subjects that have been already discussed in its pages, in order to satisfy inquiries that arise from time to time. It may happen, too, that additional facts may be elicited by the renewal of a discussion upon any subject. I am inclined, therefore, to agree with "COUNTRY CURATE" that it may not be without advantage to return to the question of Manetti stocks.

The soil in which Roses on the Manetti are grown must, of course, be the chief means of determining the adaptability of the stock to the end in view, which I assume to be this—to produce better flowers, and a greater number of them, than can be obtained by any other means in the same situation. A secondary consideration will also be—that the plants, resembling in appearance those on their own roots, which in soils that are light and not naturally strong they soon become, are therefore more manageable and less unsightly when out of bloom than standards or half standards on the briar; for there is scarcely a shrub less attractive to the eye than a flowerless, leafless Rose bush, and the ugly appearance of pruned and unpruned standards in the same naked state is noticeable to every one, but we readily pass this out of mind when we look on the lovely forms produced by them.

The soil in this part of Surrey is very different from the description "COUNTRY CURATE" gives of that of his garden in Shropshire, and both again differ from the soil of Mr. Radclyffe's late garden at Rushton. The superiority of the Manetti stock having been fully established both here and at Rushton, "COUNTRY CURATE" is quite justified in asserting that it should be tried in other places, and, I wish to add, the result of the trial should be made known.

We have read frequently in these pages and elsewhere that the Manetti stock is not advocated by rosarians who have heavy soils, and not without reason, because generally the briar does well on those soils, and the propagation of Roses on it is so simple and easy that satisfactory results are obtained without having recourse to any other means. It is also affirmed that the Manetti stock proves too strong for the Rose budded or otherwise worked upon it. Roses on their own roots also do well in heavy soils. Instances of both have come under my notice, and in submitting these notes in reply to "COUNTRY CURATE's" favourable mention of my former article on this subject, cognizance is taken of these circumstances.

As regards the influence of climate, it is sufficiently established that the Manetti is hardy enough to withstand the generality of English winters, as well as the varying character of our springs and summers. I have heard of its succeeding well in Durham and Yorkshire, and hence there is no reason to doubt equal success in Shropshire and other north-western and midland counties. It may be assumed, also, that since the Manetti stock is found to maintain the Rose grafted or budded upon it in better condition in the earlier stages of growth in light soils, which retain a higher temperature than heavy ones, the south of England may be slightly more suitable for it than the north; and, further, that in rich soils in a favourable situation the exuberance of vigour in the stock may sometimes prove too strong for the Rose worked upon it, and hence the reasonable objection of those who have tried it under these conditions.

The inquiry of "COUNTRY CURATE" embraces two principal but connected subjects—namely, the propagation of Roses on the Manetti stock, and the propagation of the stock itself. All the other points of information sought for in his recent article may be included in these.

1st, *Propagation of Roses on the Manetti.*—The stocks should be obtained in the autumn that they may be well established for operating upon in the following summer. They should be planted in rows not less than 6 inches apart; 9 inches or even a foot would be preferable if space permit. If

several rows are planted, and it is intended to remove them when the plants are sufficiently advanced to allow of removal, space may be economised by planting the rows at alternate longer and shorter intervals—that is to say, if the first and second rows are about 18 or 20 inches apart, the second and third should be 2 or 2½ feet, the third and fourth the same as the first and second, and so on. This will allow room for working the stocks with less inconvenience and risk than if the rows were at uniformly short intervals apart. The stocks should not be planted deeper than is necessary to secure the roots firmly in the soil. Before planting it will be well to notice if any buds have appeared within a few inches of the roots, and if so, they should be removed. The same precaution is even more requisite when removing established plants, as these buds in time become developed into shoots, or suckers as they are frequently but improperly called, and which prove a fruitful source of annoyance afterwards. The neglect of this precaution has added to the complaints that have, unjustly, been brought forward in argument against the Manetti.

For propagation in the open ground budding is more certain, easier, and in every respect preferable to grafting. As I stated in a former article, a carefully inserted bud in good condition will in nearly every case produce a good plant.

As soon as spring indicates signs of genial weather, towards the end of March or early in April the stocks may be earthed up 3 or 4 inches. The object of earthing up is to keep the bark moist, and this is indispensable when the stocks are to be budded, for the bud should be inserted in that part of the stock that has been covered with soil; and it should be remembered that it is not necessary to have wood of the current year's growth, but the bud should at all times when practicable be inserted in the main stem of the stock, which would, therefore, be of the previous year's growth or even older. Stocks of the previous year's growth should be preferred, as they can be operated upon nearly as easily as the current year's shoots of the Dog Rose. If the stocks are more than two years old there will be more difficulty in performing the operation, and some doubt about the success of it; also, if the earthing up is done in the autumn when the stocks are first planted, they will sometimes throw out rootlets where these are not wanted—that is, where the stock is to be budded, rendering the bark too hard for successful operation.

By the end of May the stocks will be ready for budding, particularly if the spring has been favourable. A day or two before it is intended to bud, so much earth should be removed from the stocks as had been drawn around them by earthing up. It is advisable to make the surface level or nearly so; the stocks should not be left in a kind of irregular trench, otherwise, if continuous rains follow, the water will settle around the stocks in puddles, thereby acting injuriously upon the inserted buds, which should be as low down as possible. When the ligature of the bud is fleecy worsted, a soft and at the same time pliable and strong material, which I have always found preferable to any other, if the lower end of the ligature is in contact with water that settles around the stock, the bud will be kept wet too long by the capillary attraction of the worsted, and soon rot. In heavy soils these points cannot be too strongly insisted upon, and even in light porous soils like mine inattention has been followed by casualties. Before budding all lateral and superfluous shoots from the stock may be cut off, and, if the budding is performed early in the season, the stem in which the bud is inserted should be slightly shortened.

By early budding I mean as early in the season as buds can be obtained in a condition fit for propagation, or, as we ordinarily call them, "ripe," and the weather sufficiently warm to insure success, it being always inadvisable to bud when the temperature is low and likely to continue so for a time. Now the sap of the Manetti is so active that as soon as the genial warmth of spring puts it in motion the stock soon becomes fit for the operation, so that it is by no means imprudent to bud in May from Roses that have been forced and have sufficiently ripened their wood. It is thus useful for procuring plants of new or desirable kinds earlier than by late budding. We may, perhaps, consider last season an exceptional one, for I do not recollect cutting buds from out-of-door plants so early as the end of May, which I was enabled to do last year. The first week or ten days in June were also very propitious.

When advantage is taken of an opportunity to bud early, the bud will soon "take;" in a fortnight or three weeks the ligature should be removed, and the stock further shortened to encourage the growth of the young shoot from the inserted bud.

As soon as this has attained some length, it is advisable to tie it gently to a stick, or some other support, to prevent accident by wind, and when the wood of the new shoot becomes firm the stock may be cut down to within a couple of inches of the point of union; and, if it is not intended to remove the plant for some time, it should be earthed up, covering the union with at least 2 inches of soil. I have heard it affirmed that it takes a longer time to form as strong a union of the bud with the Manetti than it does with the briar. I am inclined to believe this to be correct, and the *rationale* of it appears to be the greater activity of the sap of the Manetti, and the longer duration of its action. The tying and earthing up, therefore, may materially assist in preventing fracture.

The months of July and August are recommended as being the best time for budding; it may be done in September, but it is not advisable to defer it too long. All buds inserted in August and September should, if possible, be kept dormant all the winter. This may be effected by not shortening the stock. The ligature should be removed when the bud has taken, and it may then be left till the following spring. When it is found that the bud is about to start, the stock should be shortened as above stated. It is advised by some to cover the budded stocks with straw or other light material during the winter, but if the weather prove wet after their being so covered more injury than good results, and I think it best, on the whole, to leave them unprotected. I confess, however, that this is only a matter of opinion, and not of actual experience. Dormant buds should certainly not be buried in soil during the winter; exposure to the weather is safer.

2nd, *Propagation of the Manetti*.—The preceding notes were penned before I saw the excellent article by Mr. Cleaver in the Journal of April 17. As I fully concur in the statements there made, and believe them to be founded upon a careful observation of facts, it would be superfluous to repeat now what is there given in reference to the propagation of the Manetti by cuttings. Another mode of propagation, equally simple, is by layers. If a few old plants are reserved for this purpose, all the shoots of sufficient length sent out from the collar or bottom of the stock may be pegged down according to the usual practice of layering, as soon as the wood is ripe. If the shoots are long, more than one new plant can be obtained by slightly incurving the shoot between the pegs.

The complaint of a deficient supply of stocks has been frequently expressed of late. The reason is undoubtedly the greater demand for them arising from the increasing appreciation of the Manetti, and the growing conviction that its merits have been faithfully recorded by those who have advocated and advised its use. The adoption of it is yearly becoming more general, and the careful rosarian will value it as one of the chief means at present within reach for enabling him to obtain a permanency for his plants, and a succession of good bloom year after year which the Dog Rose very rarely affords.

Another point of inquiry in connection with the Manetti stock ought not to be passed over without notice. I allude to the selection of kinds suitable to the stock. A list of such would indeed be a long one, and among them would be several desirable varieties which are not naturally strong, but which receive from the stock more vigour than can be imparted to them by any other means. I have noticed, however, anomalies which as yet have not been satisfactorily accounted for. I have, then, to ask for the experience and testimony of other contributors. Another season may do much towards clearing up some of these discrepancies, and having extended this article beyond the limits at first intended, with the permission of the Editors, I think it will be better to postpone for a few months the consideration of those points of inquiry.—ADOLPHUS H. KENT.

PURE BROCCOLI SEED.

I was surprised by a friend venturing to remark that I should not succeed in raising Broccoli seed true, unless I covered the flowers with muslin. I had raised fair seed from Osborn's Winter White, and then, as in the present instance, having no other species of Brassica in the garden, I felt the result sound; but my friend says bees and flies will impregnate with pollen foreign to the Broccoli. What such a hybrid would be I cannot say. Give me your ideas.—GEORGEHAM.

[To preserve any of the varieties of Brassica, or the Cabbage-works, is very difficult. Broccolis, Cauliflowers, Cabbages, Charlock, and Rape, are all capable of impregnating each other. Bees will carry the pollen from the various species and va-

rieties to the others. Your friend was wrong, if by "foreign" pollen he meant any but that derived from plants belonging to the same tribe.]

BOILERS.

Mr. COOPER (page 106) treats of tubular boilers as if they were of recent introduction, and not fully tested—as if, indeed, sufficient experience of them had not been gained to warrant their being recommended. This is in the main correct, as regards the majority of that description of boiler; but there are some that have been at work for more than ten years, and of which the qualities and defects would, one may reasonably expect, have been found out in that time. The question of experience with tubular boilers falls to the ground, from the simple fact that Mr. Cooper is able to give an account of their defects.

Your correspondent draws a very unfavourable picture of the power, economy, and endurance of tubular boilers, and though he offers no data, pronounces in favour of the saddle form of boiler, and puts certain questions at the end of his communication, which I presume he anticipated would be answered in accordance with his own views.

Mr. Cooper recognises three points as essential to a good boiler—viz., power, economy, and endurance, and upon these points I beg to say a few words, both in respect to tubular, saddle, and other boilers.

1st, *Power*.—A boiler derives its power from the extent of its surface exposed to the action of the fire, the proximity to the fire of the parts exposed, and the resistance which they offer to the passage of the heat to the flue. Now, a tubular boiler is so constructed that some parts are immediately in contact with the fire, others immediately over it, all so arranged that the fire must come in contact with more than one part, if not all, before its heat passes into the flue. A saddle boiler does not expose one-half its surface to the direct and indirect action of the fire, the parts in contact with and directly exposed to it being those from which the water within derives its heat, for the parts indirectly exposed are so coated with "soot and other products of combustion," as to be next to valueless as regards heating power. These principles applied to a tubular boiler mean that one of £20 value exposes to the direct and indirect action of the fire 150 feet of surface, and is calculated to heat 1500 feet of four-inch piping, or 800 gallons of water. A saddle boiler of the value of £20 does not expose more than one-half, or 75 feet of surface to the direct and indirect action of the fire, and cannot be made to heat more than 700 feet of four-inch pipe, or about 373 gallons of water.

Take one hundredweight of coke for the tubular boiler, and a like weight of slack or small coal for the saddle boiler, with 14 lbs. of wood to each; let fires be kindled under them simultaneously, and allow in each case ten minutes grace to get under weigh or obtain a fire, and then let us see how they act. The tubular boiler will now take the whole of the hundredweight of coke, and the saddle its remaining quota of slack. It is well with the stoker minding the tubular boiler, for he may open wide the ash-pit door, and ere long he will hear the sound of the water being rapidly heated in the boiler, and in a few minutes more the noise increases. It is now high time to close the ash-pit door to such an extent as to check the draught, and thus prevent the water being heated so quickly as to rush through the flow-pipes faster than the return-pipes can bring it in to be heated. The saddle boiler, on the contrary, will give the stoker a large amount of care and labour for the whole of the time requisite to heat the water. The time required in each case will be as follows:—Fires lighted at 9 a.m., both boilers having good fires under them at 9.10, when the tubular is charged with the remainder of the hundredweight of coke, the saddle being still worked on. At 9.55 the water rises through the flow-pipe of the tubular boiler at a temperature of 180°, which is sufficiently hot for all horticultural purposes. The tubular boiler fire may now be slackened, and at the end of three hours the water still leaves the boiler at a temperature of 180°. The saddle at 9.55 does not circulate through the flow water of a higher temperature than 90°, and it is 11.40 a.m. before the water comes through the flow-pipe at a temperature of 180°, the quota of fuel being all on the fire, and more required to maintain the temperature attained by the water. The tubular will also require at the same time another 1 cwt. of coke, which will serve to maintain the water at a temperature of 180° from six to eight hours. A tubular boiler, therefore, heats double the amount of water in one-third of the time with the

same consumption of fuel as a saddle boiler of the same value. So much, then, for the power of a tubular, as compared with a saddle boiler.

2nd. *Economy*.—I find that a tubular boiler of the value of £20, and a saddle one of like cost, differ but little as to the quantity of fuel consumed. A tubular boiler consumes 1 ton of coke per week for the twenty-six weeks of winter, and 1 ton in ten days during the other twenty-six weeks of the year, or 44 tons per annum, which at 7s. per ton amounts to £15 8s. A saddle boiler consumes 1 ton per week for twenty-six weeks, and 1 ton in twelve days for the other twenty-six weeks, which for 41 tons of slack coal at 6s. 9d. per ton amounts to about £13 16s. 9d. Now, this is when the whole of the piping is required to maintain suitable temperatures in stoves, forcing-houses, and pineries, and this tests the power and economy of boilers more than where the boiler is employed to heat a miscellaneous range of houses, some being stoves requiring artificial heat at all times, others vineries that need artificial heat for six or eight months, or it may be only as many weeks, the same remark applying to greenhouses and cool houses generally. For such I find a tubular boiler consumes 1 ton in ten days for twenty-six weeks, and 1 ton in twenty-one days during the other twenty-six weeks, or 27 tons of coke per annum, value £9 9s. A saddle costing £20 employed for a like purpose consumes 1 ton of slack coal in eight days for the twenty-six weeks of winter, and 1 ton in eighteen days for the other twenty-six weeks, or 32 tons per annum, and this at 6s. 9d. per ton amounts to £10 13s. 11d.

A tubular boiler heating 1500 feet of four-inch piping costs, when employed for heating houses requiring high temperatures, £15 8s. per annum; a saddle boiler heating between 600 and 700 feet of four-inch piping, £13 16s. 9d.; but when the houses to be heated are such as require in part high, and in part low, or occasionally high temperatures, the yearly expenses of fuel for the tubular boiler are £9 9s.; and for the saddle, £10 13s. 11d. It is not on the score of consuming less fuel that we must look for the economy of saddle boilers, nor in the item of labour, for a saddle boiler takes double the amount of labour and attention that a tubular one requires. Saddle boilers increase the hours of labour, cause much night work, make late goers-to-bed of those who are often required to be early risers, especially if the means are limited to one boiler, and they are besides clumsy, idle, and not economical in working. Any merit they may have would seem to be confined to their endurance.

3rd. *Endurance*.—From experience of the practical working of tubular and saddle boilers, I can say this much for tubular boilers—1st, I have not known any removed as inefficient, and replaced by saddle or other descriptions of boilers; 2nd, They do not fail through the cracking of the "lower rim to which the upright tubes are joined;" 3rd, Those which have been fixed are still doing that which they were at first calculated to do, and did perform. What I have to say practically of saddle boilers is—1st, That they are slow in heating; 2nd, That they require great labour and attention; and 3rd, That they waste half the heat of the fuel consumed. Again: I have known saddle boilers removed as inefficient, six of them in one instance, and replaced by one tubular boiler, which last consumed no more fuel than two of the saddle-boiler furnaces.

I really have no further experience of tubular boilers in point of endurance than that I know them to have stood the wear and tear of fire and water for ten years, and in one instance for twelve years, many from six to ten years, and very many from three to six years. In no one instance have I heard any complaints of the non-heating of tubular boilers from the deposit of soot and other products of combustion, and I do not think that they are liable to this drawback to anything like the same extent as a boiler heated by coal. It is only reasonable, if a boiler does not heat so quickly after some years as it did when first erected, to attribute the cause to the coating of the parts exposed to the action of the fire with soot and other products of combustion resembling coal tar. From experience I am happy to say that there is no deposit of soot, and that no products of combustion resembling coal tar are deposited on any part of a tubular boiler; for as these boilers consume coke smoke is wanting, and therefore there cannot be sooty deposits, nor gas tar, as that is extracted. There is, however, a deposit, and that is of dust, which lodges on the lower rims to which the upright tubes are joined; and the parts immediately over the fire have a certain deposit of some kind consequent on the action of the fire, but it is one vanishing under a strong fire, or it scales off without its being necessary to clean

it off, as some do. A saddle boiler, and it of course burns coal, soon becomes coated with soot and a substance much resembling coal tar. This and all other deposits vastly impair the heating powers of a boiler, and, unless cleaned off, the boiler can only be heated by an extravagant consumption of fuel.

I entirely concur in the views expressed by Mr. Cooper, that tubular boilers are difficult to clear of any dust that may be deposited on the parts farthest from the fire (I cannot entertain the deposit of soot and other substances consequent on combustion applying to boilers consuming coke), but on these dust cannot well rest, as the tubes are vertical, and whatever there may be is easily removed by employing a brush similar to a bottle-cleaner, with a long twisted wire handle; but how are we to clean the side flues of a saddle boiler, and free those parts of soot, &c.? The difficulty of doing this renders all such boilers less powerful every day; no matter how much the boiler is scraped and cleaned, something fastens itself on the surface exposed to the action of the fire which no amount of cleaning effectually removes. This not only affects their efficiency, but their endurance as well, and the decay of the iron is to be measured by the deposit of soot and other products of combustion on the iron. A saddle boiler is more liable to this than a tubular one, and how the saddle is to be more durable I am at a loss to know.

I am certain that it is not outside a tubular boiler that we must look for that which impairs its efficiency and endurance, but inside for the corrosion of the iron and the lodgement of sediment within the pipes. This I find is dependant on the water employed, and on the quantity of water passing through the boiler. In a tubular boiler the circulation of the water is much more rapid than in one of the saddle form, and double the quantity passes through it; I therefore think that a tubular boiler will be sooner choked, owing to the corrosion of the iron, than a saddle one. In that case the former will be less durable than the latter, for its parts being narrower they must necessarily be sooner closed. In what other way tubular boilers are likely to be less durable than those of the saddle form I must leave it for others to determine; but tubular boilers are the most powerful and economical of those of which I have had experience. It is to me a matter of perfect indifference what form is preferred, for boilers scarcely differ in principle, and all have their defects. I look upon perfection in boilers as not yet attained, nor likely to be for a long time, if ever.

The principle of tubular boilers seems to be the exposing as much surface as possible to the direct action of the fire, and placing as much of it as can well be done in contact with the fire in order to heat the water quickly; but it is questionable whether employing horizontal tubes is the safest mode of doing so. Horizontal tubular and circular rims are calculated to expose a greater surface to the fire than vertical tubes; but the very thing that facilitates the heating of water hinders its circulation; for the circulation of hot water in a vertical tube is more rapid than in one that is horizontal. The object should be to heat the greatest quantity of water by placing the parts in contact with and directly exposed to the fire in such a manner that the best effect will be produced, and then to get it out of the boiler as quickly as possible: hence the upright tubes for the upper part of the boiler, they receiving what may not inaptly be termed indirect heat, or that passing up towards the flue after it has been acting on the lower parts of the boiler.

Of two conclusions, I am certain, 1st, that if boilers are to be made more powerful, it must be by exposing a greater amount of surface, or bringing into contact with the fire more of the surface of the boiler, as is the case with the water-jacket in Clarke's upright tubular boiler. 2nd, That if boilers are to be made more economical of fuel, that economy must be effected by having them so constructed that the greatest resistance is offered to the escape of the heat towards the flue, so as to employ it in raising the temperature of the water within the boiler, instead of allowing it a free passage to the chimney to expend itself in space. This obstruction to the escape of heat seems to be happily provided for in the terminal saddle boiler, which is, in my opinion, the greatest stride made for a long time in heating by hot water with the saddle boiler, though even that is by adopting a principle previously applied to tubular boilers. I think that the saddle boiler will, notwithstanding that improvement, lack much of the power of a tubular one, and I believe that it will not heat so much piping by one-third as a tubular boiler of the same first cost, and with an equal expenditure of fuel. The only advantage I ever saw, or I believe

ever shall see in a saddle boiler, no matter how improved, is that it will burn anything and everything combustible. Tubular boilers will not, or rather ought not to do so, or their parts become so clogged with soot and other products of combustion, as to be practically the reverse of powerful or economical.

Mr. Cooper concludes by asking, "Shall we, then, continue to erect upright tubular boilers?" I am glad that he has made the distinction, "upright tubular," for horizontal tubular are those requiring the chimneysweep every morning to clear away the soot and dust. They will never do unless heated by something not emitting smoke. My answer to Mr. Cooper's question is in the affirmative, or "Yes, until a boiler of greater power be invented," and that is not yet done.

"Shall we return to the good, old, and long-tried saddle?" Well, no. For detached houses it may do; for long ranges of houses it is not economical nor efficient.

Mr. Cooper's last query I will not presume to answer, but I have no doubt the best boiler that will burn any kind of fuel, is the terminal saddle boiler.

In conclusion, I would point to the old and long-tried flue for economy in heating small detached houses, or where much capital would have to be invested, if heating had to be effected by hot water; to a boiler of the saddle pattern for large detached houses; and to the tubular form where coke can be had, and there is much glass.—G. ABBEY.

A LITTLE MORE ABOUT TOBACCO.

Your correspondent, "X," (page 287) seems to infer that when I wrote the article on "The Growth and Manufacture of Tobacco," I ought to have stated how much might be legally grown on English soil without infringing the law. I must confess that when I penned the above paper I was in ignorance as to the quantity allowed by law to be grown, but fancied it was about a pole.

I may also state here what I omitted in my last, that I sow my seed about this time (April 23rd), because by the time the seedlings are ready to prick out, the first bedding plants will be put out in the flower garden, so disengaging plenty of small pots. As many tobacco plants as will be required are then potted singly, they are started in any warm house where there is room, and hardened off in the cold frames which have been used for bedding plants. Were it not for the want of space, a want felt in most gardening establishments in the months of April and May, I would sow and put out my plants earlier. I do not think that the system adopted by your correspondent, "RUC" (page 270), of allowing his plants to remain entire until the approach of frost, is preferable to gathering the lower leaves as they become ripe. When the plants are luxuriant, the lower leaves are liable to decay before the plant is fully developed, they then become useless, and the best and largest leaves are lost. I prefer securing the lower leaves, and drying them as they attain maturity, which will be about the middle of September. I have gathered the plants entire, but found it attended with waste.

I am glad that the subject of growing Tobacco for fumigating-purposes seems to be gaining in interest. I was in conversation the other day with a gardener who is at the head of one of the first establishments in the kingdom, and he told me that the expense of fumigating for the year was becoming a very serious item, and one which it would be very desirable to obviate. There are very few gardens in which there is not as much space at command as will afford room for a sufficient number of Tobacco plants to serve for the year. I may also add that a sixpenny packet of seed from any respectable seedsman would plant a quarter of an acre of land.

Since I wrote the communication at page 137, I have changed my position, and having to supply the wants of a large establishment from only a limited area of kitchen garden ground, of which every inch has to be cropped with vegetables in order to meet the incessant demand, I purpose growing my Tobacco plants this season between the Asparagus-beds, and as I find the ground is very rich, I expect an abundant harvest from them.

Allow me to state in conclusion, that those who intend to grow Tobacco must be careful in the drying and storing it away. If it is too dry it will not sweat, and then its essential oil, in which its value consists, is lost; or, if the leaves are too full of moisture they are liable to decay.

As the pages of "our Journal" are always open for amateurs as well as the professional gardener to relate their practice on all subjects of interest, I trust some of its numerous readers,

who may be induced to try the experiment of growing their own Tobacco, will in the autumn, when their plants are gathered and stored away, give us the result of their experience.—QUINTIN READ, *Port Hill Gardens, near Burslem.*

MILDEW ON ROSES.

MILDEW, or white fungus, is a sad malady when it attacks Roses early in the year, before the new wood is confirmed. If it appears late, it does not so much signify. Anything that obstructs the lungs must affect the plant. Flowers of sulphur may be beneficial under glass, but out of doors I never saw any good result from its use.

Mildew is called "the daughter of drought," because long-continued drought thickens the juices of the plant, and makes the young folioles sticky; fungus then adheres, and in favourable weather it is developed. Abundant watering at the root and over the leaves in hot weather, would probably prevent it; but when it has once obtained a hold of the plant, an abstergent lotion is the best remedy. Put 2 ozs. of blue vitriol into sufficient hot water to dissolve it, and then put the solution into a stable-bucket of cold water, and pour it with a fine-rosed watering-pot over the leaves. I have known it cure thoroughly a line of *Géant des Batailles* (much given to mildew, discarded by me now), when the mildew has been rooted deeply into the texture of the leaves. If "HELEN" (your inquiring correspondent) has only a few Roses, she may sponge it off or rub it off with the finger and thumb on its first appearance. *Baronne Haliez* is another Rose which is never free from mildew.

In hot, showery seasons mildew seldom appears on the Rose, nor does it then do any amount of harm.—W. F. RADCLYFFE.

[Mr. Radclyffe now resides at Okeford Fitzpaine, near Shillingstone, Dorset. He has left Tarrant Rushton.]

ROYAL HORTICULTURAL SOCIETY.

WEEKLY SHOW, *April 28th*.—For the best collection of twelve miscellaneous plants the first prize was awarded to Messrs. Cutbush and Son, of Highgate; and also for the best collection of eighteen Hyacinths and eighteen bulbs in flower. Mr. Morgan, gardener to the Marquis of Townshend, Herford, received a prize for a very fine punnet of Keens' Seedling Strawberries, which were large and handsome. Rev. Geo. Cheere, of Papworth Hall, received a first-class certificate for a tray of *Anna Boleyn* Pinks, and one for handsomely grown plants of the large-flowered or Giant Mignonette, beautifully done. Mr. Bartlett received a first-class certificate for a collection of bulbs, and a prize for a fine specimen of *Adiantum cuneatum*. Mrs. Hooke, Fulham, received a first-class certificate for a collection of *Cinerarias*; and Messrs. Lockett, Brothers, for a collection of *Calceolarias* and *Pelargoniums*. Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, obtained a prize for a collection of miscellaneous plants; and Mr. Young, gardener to R. Barclay Esq., of Highgate, received a first prize for a very meritorious collection of vegetables.

HORTICULTURAL DINNER.—We understand that Lord H. Gordon Lennox, M.P., has kindly consented to take the chair at the dinner to be held at St. Martin's Hall (May 24th), during the week of the International Horticultural Exhibition.

THE MANGO AND MANGOSTEEN.

I, in common with many of your readers, have been much interested in the papers by "J. H." on the cultivation of tropical fruits that have from time to time appeared in THE JOURNAL OF HORTICULTURE. Several of my friends who take a great interest in these matters have gone to considerable expense in the endeavour to rival the doings of "J. H.," and to secure, as he would lead us to expect, such a supply of the fruit of the Mangosteen as would not only furnish their own tables but those of their friends.

I have lately heard in more than one quarter considerable doubts expressed as to whether "J. H." has really done what he professes. On the one hand, highly skilled cultivators assert that the instructions given by "J. H." cannot possibly succeed, as they are contrary to the conditions under which the tree naturally grows; others say, Could such a feat in horticulture be performed in England without some person having seen it? Now, I should be glad if "J. H." will, for the satisfaction of your readers, state where he "obtained fruit for three successive years (1859-60-61), from one small tree." It seems strange that such a circumstance should have occurred

and created no excitement in the horticultural world, when the production of a solitary fruit at long intervals in some of our most extensive establishments throws the whole community into ecstasies.—B. II.

FRUITS IN THE ORCHARD-HOUSE AND GARDEN.

I HAVE heard and read of orchard-houses in various parts of the country, but I am not aware that they exist to any extent in this county, Shropshire. My first experience in this matter dates from last autumn twelvemonth, when I had a lean-to, 20 feet by 12, erected. The Peach and Nectarine trees, owing to the pots not being ready when they arrived, remained in an outhouse in the baskets, only partially unpacked, for nine or ten days, being kept too dry; and when afterwards potted, being overdosed with water, they cast their buds, and so far for the first season were a failure. Perceiving, however, from the character of growth last summer, and a nice sprinkling of Plums and Cherries, that orchard-house cultivation was likely to be a success, I, last autumn, built another house the same size as the preceding, and matters at present are very promising.

Having understood that Apricots were not easily fruited in pots, I am pleased to find that the two I have, a Kaisha and Moorpark, have their fruit set very thickly, so that the scissors will have to be used pretty freely in the thinning process. Here let me say how well orchard-houses are adapted for retarding as well as protecting the blossom. This matter was strongly recommended by the late Mr. Errington, and is, I conceive, extremely important. Having had occasion to go some distance from home on the 23rd of February, I was surprised to see the walls covered with Apricot bloom at that early date, while my trees were scarcely showing white at all. I had had the ventilators of the house for the most part open night and day throughout the whole of that unusually mild January, and hence the buds were still in embryo when others were bursting into bloom. We may easily suppose where protection has been withheld what has been the result of an inclement March. A friend in the neighbourhood, who had a fine bloom of this fruit on his wall, told me a few days ago that half a dozen would be the outside of the produce. Mr. Rivers, in his book, recommends the ventilators to be shut night and day during January. The advice is, no doubt, sound in the main, but the best rules must occasionally be departed from.

Though the Peaches and Nectarines are at present pictures of beauty in their full bloom, it is yet too soon to speak about results; but I hope in the autumn to report good progress in that direction. The Plums seem especially promising, and I can see already that a Reine Claude is setting its fruit so thickly that some hundreds will have to be taken off.

With regard to fruit generally, it is remarkable how little the theory of thinning in productive seasons is understood and practised, the results of its neglect being deteriorated produce in the current year, and a total failure in the next. I cut off last year three thousand from one Orleans Plum tree, and it would have been all the better if I had taken off a thousand more. A crop of two bushels still remained.

The soil of my garden, a tenacious loam on a clay, or, otherwise, rocky subsoil, seems to be very suitable for the generality of fruit trees. The Ribston and Hawthornden Apples do not canker in the least; and from that decaying of the ends of young branches so often seen, my trees never suffer. Strawberries never fail with me. The British Queen, of which complaints are so frequent, always fruits abundantly. The last two dry summers have been no exception. I make fresh plantations every other year.

Like other people, I have been plagued from time to time by the birds taking the buds. Let not person, however, rashly charge sparrows with the offence. They are bad enough in their way, and those who have Plas coming up where sparrows abound must be on the look-out, or the rows will present a very naked and unsatisfactory appearance; but my opinion is, these birds never injure a bud. The real depredators are bullfinches, tomtits, and, I am inclined to think to some extent, chaffinches. These are sometimes sad nuisances. I never found till this year the buds of the Quince taken, but one in my garden a month ago, had in two days every incipient blossom devoured or destroyed.

Gooseberries, however, are the special objects of their attacks. A gentleman in the neighbourhood informed me, that he had on this account every Gooseberry tree in his garden grubbed

up. One does not, however, like to be beaten after that fashion. For some years I delayed pruning till late in the spring, and persevered with the thread and egg-shell system, but to little purpose. For the last two years I have pruned early, and well whitewashed every shoot and bud with considerable success. I had a good crop last year, and have at present the prospect of an extra large one. I think I have derived one advantage by the buds being so taken formerly. Not enduring the naked appearance of the trees, I cut them in close, and am now decidedly of opinion that the young wood for the Gooseberry is the best, especially for the preserving aorta. Most of my trees, now twenty years old, might well pass for five or six, all the wood of some of them not being older than three years. People are sometimes astonished to see the strength of the shoots, some of them upwards of 2 feet long, and covered with buds or fruit.

There are various specifics for extirpating the Gooseberry grub. I have managed for years to keep it down by taking off the first perforated leaves. The grubs are easily enough seen, and in five minutes as many are destroyed as might constitute a legion.—J. M.

PEACH-GROWING IN NEW JERSEY.

I AM a subscriber, and on the principle of distance lending enchantment, derive, perhaps, as much satisfaction from your Journal as those nearer your door.

A writer on the "Meteorology of Fruit-tree Houses," in the Number of December 19th, says, "It would be highly interesting to learn from the United States, taking New Jersey for instance, where Peaches are grown so largely, how the day and night temperature varies in the ripening season, and whether it is ever as low as our brick walls and orchard-houses." As I live in New Jersey, and, indeed, in the *Jerseyist* part of New Jersey, I propose to give you a few facts on the subject referred to.

Peaches ripen here chiefly in August and September. The maximum temperature in August is about 95°, and the minimum is from 52° to 55°. In September the maximum is from 78° to 80°, and the minimum about 40°. In August, the weather is generally of a sultry heat both by day and by night, especially during the earlier part of the month; but towards the end of the month the nights become more cool and refreshing, often with very heavy dew. The minimum mentioned above is chiefly reached during a cold storm from the east or north-east.

I live three miles from the salt water, and fifteen miles from the sea. In my neighbourhood the soil is extremely sandy. Indeed, in very much exposed situations, the wind drives the sand about to such an extent that scarcely anything in the way of vegetation finds a resting place long to grow, even if it could find any nourishment for support. On one of our small hill sides, fully exposed to the violent north-west winds, a sort of Heather (*Hudsonia ericoides*), is the only plant that has gained a foothold, and maintained it. This is only found in dry sand near the coast.

For miles about me, certainly not more than one acre in ten has ever been cultivated. The woods having been nearly all cut away, a low growth of Pine, scrub Oak, and underbrush has sprung up, clothing most of the rounding hill slopes as far as the eye can reach. This underbrush is, in great part, composed of Blackberry and Whortleberry bushes, the fruit of which begin to ripen early in July. The berries are picked by women and children, and sent to New York, twenty-five miles distant, where they find a ready sale, at prices varying from 2d. to 6d. a quart, of your money. When this woodland is cleared, the sand is found to be rich in vegetable matter, as you may suppose, and, with the aid of a dressing of farmyard manure, grows many fruits, flowers, and vegetables in perfection. Peach trees in this soil make an astonishing growth, and the flavour of the fruit is the concentration of excellence, far finer than when the trees are grown on the heavy land a few miles distant. The trees themselves will not live so long as in heavier soil; but Peach orchards are easily renewed, and in fruit ten years of perfection are better than twelve of mediocrity. In this case, "a short life and a merry one" is no bad motto.

At the risk of troubling you with too long a letter, I want to say a word or two regarding the soil, as influencing the flavour of fruits, a subject, I think, not sufficiently considered. As an example: Melons which are wonderfully fine in our new and sandy ground, when grown on a heavy clay loam, about seven miles distant, are really not worth eating. So, too, the Pear

Loise Bonne of Jersey, on the Quince stock, is of very first quality with us; on the heavy soil it is astringent and hardly second-rate. Then, too, there is an American Grape, the Diana, highly esteemed in many parts of the country, but in our soil strongly and offensively musky.

Should you care to hear from me again, I may write about some of our New Jersey wild flowers, Ferns, &c. In none of your English catalogues do I see the name of the climbing Fern (*Lygodium palmatum*), of which I send you two leaves. It is rather rare. In all my wanderings I have only found it in one place in our woods. It gracefully twines among the bushes, reaching a height of from 2 to 4 feet. This Fern is so hardy, that the leaves I send you were picked yesterday (March 29th), perfectly fresh and green, after having endured a frost of 20° below zero this winter, the coldest weather ever known here.—GEORGE SUCH.

[Such communications are always interesting, and we shall be glad to hear from you again. The Fern which you sent was correctly named *Lygodium palmatum*; it is to be found in several English catalogues.—Eus.]

A NEW HOE.

I THINK I have a good thing now; and, with your permission, will tell your readers what it is. Being some time since in the store of Mr. Alfred Bridgeman, my attention was attracted by a curious-looking implement, painted red; in fact, it was the red paint that first drew my attention. On examination, this curious implement proved to be a hoe. At first I thought it had been made "wrong end foremost;" this, however, was not so; still, I am inclined to believe that it might be made both ways with advantage. It will be seen that the hoe is in the form of a wedge, both the front and back edges being sharp. It thus has a double motion, or, in other words, a pushing and a draw cut, which enables one to get over the ground very rapidly. From the form of the hoe, the cut on both sides is a draw cut, like that of the knife, the very best that can be used. The wedge form, too, while it presents a very large cutting surface, causes the hoe to enter the ground and pass under the surface with a comparatively small expenditure of power. It will naturally be inferred, on looking at the engraving, that the draw motion of this hoe is easier than the thrust, and this is the case.

I have used this hoe during most of the present season. It is decidedly the best tool of the kind I have ever used; so good, indeed, that I am unwilling that others should remain in ignorance of it. At first I thought it was just a little awkward, as many others may; but I soon got the "hang of it," and then it worked like a charm. I use it with both motions, backwards and forwards, and am astonished how rapidly I get over the ground. The draw motion is admirable. I am sure I can do twice as much work with it as I can with the common pushing hoe, and do it easier, if not better. With the draw motion I can cut down with ease weeds so large that I cannot move them with the common hoe.

Of course, nobody should let weeds of any kind grow to a large size; but they will sometimes in spite of you, especially in a wet season, and then it is well to know that there is an implement that will cut them down like grass. This it does because of its draw-cut.

Another advantage possessed by this hoe is that you can cut close up to a row of plants without danger of cutting them off.

The points on the lower side pick out the weeds nicely from between and around the plants, and thus save much stooping and hand-work.

If this should meet the maker's eye, I would suggest to him that he make the handle longer: it is now too short. He should also make at least three sizes—6, 8, and 10 inches wide. The present one is 8 inches, which is too wide for much work to be done in the garden.—P. B. MEAD, *New York* (in *American Gardener's Monthly*).

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

PEPEROMIA MARMORATA (Marble-leaved Peperomia).—*Nat. ord.*, Piperaceæ. *Linn.*, Diandria Monogynia. Native of South Brazil. Leaves dark green, variously marbled with very pale green.—(*Bot. Mag.*, t. 5568.)

ERICINELLA MANNII (Camerouns Mountain Heath).—*Nat. ord.*, Ericaceæ. *Linn.*, Tetrandria Monogynia. Native of Fernando Po and Cameroun Mountains, at elevations between 4000 and 10,000 feet. Flowers rose-coloured.—(*Ibid.*, t. 5569.)

POLYCHILOS CORNU-CERVI (Stag's-horn Polychilos).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Moulmein. Imported by Messrs. Low. Petals yellowish green striped with reddish brown.—(*Ibid.*, t. 5570.)

TACSONIA VAN VOLKEMII (Van Volkem's Passion-Flower).—*Nat. ord.*, Passifloræ. *Linn.*, Pentandria Trigynia. Native of the temperate region of New Grenada, and promises to eclipse the *Lapageria*. Flowers crimson.—(*Ibid.*, t. 5571.)

MILTONIA ANCEPS (Two-edged-stemmed Miltonia).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Brazil. Re-introduced by Messrs. Low. Sepals and petals yellow; lip white, dotted and striped with purplish crimson.—(*Ibid.*, t. 5572.)

MUSSENDA LUTEOLA (Captain Grant's Mussenda).—*Nat. ord.*, Rubiaceæ. *Linn.*, Pentandria Monogynia. Introduced by Captain Grant, companion of Captain Speke, from the country near the head of the Nile. Flowers primrose-coloured; one segment of the calyx forms a yellowish white leaf.—(*Ibid.*, t. 5573.)

EPIPHYLLUM TRUNCATUM ELEGANS.—Flowers scarlet, with purple centre. Sent out by Mr. W. Bull, Chelsea.—(*Floral Mag.*, pl. 285.)

PELARGONIUM PELTATUM ELEGANS.—An ivy-leaved kind. Sent out by Messrs. E. G. Henderson & Son. Flowers delicate pink.—(*Ibid.*, pl. 286.)

MARANTA ILLUSTRIS.—Native of the High Amazon in Ecuador. Leaves deep green above, barred with still deeper green, and a zig-zag band round near the edge coloured yellowish white; underneath dull purple.—(*Ibid.*, pl. 287.)

DOUBLE PRIMULAS.—Sent out by Messrs. F. & A. Smith, Dulwich. *Kermesina plena*, rosy carmine. *Queen of England*, white with rosy tinge.—(*Ibid.*, pl. 288.)

GLADIOLUS.—*Our Little Lucy*.—"This is one of the beautiful varieties of *Gladiolus* which have been raised by Mr. Standish, of Ascot. It is due to the successful efforts of Mr. Standish to state that he has contributed very largely to the improvement manifested among these showy popular flowers. He has, indeed, as respects the status of English-raised varieties, placed them quite on an equality with those of continental origin, and what M. Souchet's *Gladioli* are amongst those raised in France, Mr. Standish's novelties are amongst those of English parentage. Indeed, we question if some of his flowers—that named John Standish, for example, now unfortunately lost to cultivators—have ever been equalled in those characteristics which mark high quality in the flowers.

"The variety we now figure, by a process which scarcely does it justice, has already won a position for itself in the ranks of floriculture. It was shown at a meeting of the Floral Committee on the 27th of September, 1864, and on that occasion won a first-class certificate. In the report of the meeting referred to, it is spoken of in the following terms:—"A very fine and novel variety, of a rosy magenta colour, striped and splashed with white; the lip segments feathered with purple. It will be quite an acquisition among these showy autumn flowers."—(*Florist and Pomologist*, v., 65.)

FRIILLARIA MELEAGRIS.—This is now in blossom in several of the moist meadows about Oxford. I picked a good handful

this afternoon (April 21), in Christ Church meadow, on the south side, near the University barges on the river, among which were several varieties—red, brown, white, and yellow.—HENRY BURNET.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE the trenching of ground as it becomes vacant, and during the dry weather keep it well forked about. *Asparagus*, the young plants will now be ready for planting; if the ground has been properly prepared, stretch a line and take out a trench sufficiently wide and deep to allow of spreading the roots, then cover the crowns about 2 inches deep. In strong imperfectly drained soils, sand should be placed about the roots and over the crowns. The roots should be taken up carefully, and any which appear to be decaying about the crown should be rejected. Now is also a good time to sow the seed in drills about an inch deep, scattering it thinly, and covering it evenly with the finest of the soil. The seeds to be sown in drills 15 inches apart, thinning out the plants in the rows to 4 inches apart to furnish plants for transplanting after one or two seasons' growth. *Broccoli*, sow Early Purple and Myatt's White Cape, also Walcheren for late autumn use. *Beet*, sow a full crop of Red, if not already done. *Brussels Sprouts*, prick out the seedling plants of the earliest sown, and also of Savoys, to make them stocky for final transplanting. *Cauliflowers*, draw the earth up to the most forward, and give plentiful applications of liquid manure. *Celery*, continue to prick out; this must always be kept well supplied with water, rapid and continuous growth being a very essential point in its cultivation if it is required large. If the earliest sown plants receive any check from drought the chances are that they will run to seed. *Dwarf Kidney Beans*, sow a full crop, and *Scarlet Runners* if it be preferable to sow in the open ground, instead of transplanting, as recommended last week. In some soils wireworm is very apt to attack the cotyledons during the progress of germination—to remedy which, after the Beans are laid in the drills, water them with a liquid formed of one gallon of ammoniacal liquor from the gasworks, diluted with six or eight gallons of water according to the strength of the liquor, after which let them be covered with 2 inches of charred wood or refuse, and the ground levelled over them. The charred materials appear to be peculiarly agreeable to them, as they come of a most luxuriant dark green, and are very prolific. *Lettuces*, repeat the sowings of all sorts, and thin out and transplant those advancing as occasion may require. *Turnips*, sow a good breadth, the ground for which should be well dressed with wood ash or charred refuse. Hoeing, surface-stirring, and thinning out advancing crops must be persevered in with diligence and activity.

FRUIT GARDEN.

Great activity must prevail in this department. See that the soil is well pulverised about the roots of the trees, and that all newly-planted trees are sufficiently mulched. Keep a good look out for the numerous tribes of insects, and apply remedies in time. Continue moderately the disbudding of Peaches, Nectarines, and Apricots. When Vines have pushed sufficiently to distinguish the fruit-bearing shoots, let all superfluous ones be immediately removed. The blossoms of Pears and Plums are so thick that we would suggest the propriety of removing a portion, but perhaps it may be said, Let frosts do its work first.

FLOWER GARDEN.

The present is unfavourable weather for planting evergreens, owing to the prevalence of dry cutting winds. As it is more than probable that where much planting was intended, part of it may yet remain on hand, we may observe that some kinds of evergreens may yet be safely removed, taking the precautions to water them at first planting and occasionally afterwards, to well mulch the surface, and to damp the foliage over in the evenings of dry days. These attentions, which are indispensable should dry weather occur, will enable late-planted evergreens to start in most cases freely. We have found Hollies, Portugal Laurels, Evergreen Oaks, Red Cedars, Arbor Vitæ, &c., take root freely now. Another sowing of annuals may now be made either on an open border for transplanting, or on small squares of turf laid with the grassy side downwards. When the plants are up, the pieces of turf, with the plants, may safely be removed to their final quarters. As the planting-out season approaches, have everything ready for hardening off the plants, that they may experience no check by removal, and

turn over and well work the soil to bring it into a proper state for planting.

GREENHOUSE AND CONSERVATORY.

Among winter-blooming plants we have few that are so attractive and so useful as *Gesnera oblongata* and *Euphorbia jacquiniiflora*, both being profuse bloomers and remaining long in beauty. These should be extensively grown wherever winter flowers are valued, and if at the expense of neglecting some of our more recently introduced subjects, they should be afforded every necessary accommodation and attention at the present season, in order to secure good specimens for next winter. Also, attend to *Correas*, affording them sufficient pot room and a growing temperature, so as to induce free growth at the present season, and have the wood well matured early in autumn, which is the secret of having them finely in bloom throughout the winter. *Primula sinensis*, especially the double varieties, is also deserving of every attention and should not be neglected at the present season. *Fuchsias* intended for large specimens will require to be shaded from bright sunshine, and will be greatly benefited by a liberal supply of manure water. With cold nights and scorching days, there is some difficulty in managing the plants in the conservatory. The shades, if not already on, should be put on forthwith, as until we have more genial weather it will be found more advantageous to shade during the middle of the day than to admit strong currents of dry air. The newly-shifted plants in the greenhouse are now beginning to feel the benefit of the new soil, and if properly encouraged will grow rapidly, endeavour to secure clean, short, stubby growth, and strong foliage. Those plants which have fairly taken hold of the new soil—such as *Boronias*, *Pimeleas*, &c., and which require stopping to make them bushy, should be stopped at once. Keep a moist atmosphere by sprinkling the house twice or thrice a day.

STOVE.

Attend to training the twiners as they advance in growth, and do not allow them to become entangled before giving them attention. Attend, also, to the stopping and training of other plants, and afford those growing freely plenty of pot room. Continue shifting all Orchids that require it. Now that the growing season has fairly set in, care must be taken that nothing suffers from want of water. Apply the syringe liberally, but not using too much force, and early in the morning before the sun shines strongly upon the house, at the same time giving a little air to prevent scorching until the shade is let down. Continue this treatment during the present month, and about the 10th discontinue fires, and between eleven and twelve o'clock thoroughly wet all the paths, walls, &c. This will suffice for the day unless it is very warm weather, when a sprinkling from a fine-roset syringe will be found necessary, but in no case must water be supplied after midday, when the fires are discontinued. In dull, cold, or wet weather little or no water must be applied; on the contrary, a little fire for two or three hours may be necessary. The natural lowering of the temperature would be attended with much harm if the atmosphere were overcharged with moisture, for the condensation which takes place under these circumstances settles upon the flowers and destroys their beauty. This can be prevented by proper attention to airing and a judicious application of water. Keep up a pleasant temperature of from 70° to 80° by day, and by night it may be safely and beneficially allowed to go down to 60°.

PITS AND FRAMES.

Continue to pot-off rooted cuttings. Those potted off at a former period will be now becoming established in their pots. Remove them from the hotbed to a cold pit, and plunge them in sand. See that they do not want for water and shading during hot sunny days. Attend frequently to the stopping of the shoots to induce a robust bushy growth.—W. KRANE.

DOINGS OF THE LAST WEEK.

HARDLY ever knew such a week for the water-pail. A fierce, cloudless sun, and a dry parching wind, tried everything, and especially whatever was fresh planted, or fresh potted. All the nice rules frequently given for watering had to be set aside, and the spout and the rose of the watering-pot, in conjunction with shading and syringing, had to be brought into requisition without ceremony to keep things alive. The change that the sun has made in the pastures and fields is wonderful. Now is seen the impropriety of ploughing or digging heavy soil when in a

wet, claggy condition. It is now like so many lumps of iron, defying rakes, rollers, and elod-crushers. A farmer told us the other day, that it would have paid him better to have kept his horses at home, and paid the men for a holiday. The wet weather so long continued, and other causes, have thrown us behind with our work, and now it would be a privilege to be able to make each man into three.

Now is a good time to turn a horse in to roll the lawns thoroughly, as little mark will be left by his feet. It is a sad waste of time and labour, except in small places, to make three or four men draw a heavy roller, and a light roller is of little use at present. If lawns are thoroughly and heavily rolled this month, they will be much more easily mown and machined during the season.

As we are very busy, on a part of the lawn, instead of mowing, we merely swept the Daisies off with the Daisy knife. Several readers have written to us hoping and believing we make too much of the expense of a lawn. We know full well that when hope is buoyant and strong, it requires only a short journey to reach belief; but "facts are stubborn things." The proprietor of a pretty small place informed us lately, that he was coaxed into enlarging his lawn, on the faith that it would not involve more than an extra twenty-pound note per annum; but five times that sum was nearer the mark. It is all very nice to dream of switching it over with the scythe, or vastly more economically running a small hand-cutting machine over it; but disappointments and untidy lawns would alike be avoided if it were borne in mind, that in general seasons, lawns to be nice ought to be gone over at least three times a fortnight, from April to November, and several times before and after these periods.

From a mass of other work we have never been able to have the lawns here presentable until the middle of June, being obliged to content ourselves with keeping the most exposed and particular parts. In many places, part of what is considered lawn, or kept grounds, might be left in a comparatively rough state, mown merely several times in the season, and with little detriment to the general effect; but such a mode of managing small lawns close to a residence is altogether out of character, and no lawn, or one half or quarter the size, would be better in every way. To a number of explicit inquiries as to the time and labour involved in keeping certain spaces of lawn, we would give, and can only give, the general answer, that there is such a difference in grass, and in the expertness of men becoming used to their work, that before making additions it is well to note carefully the time required to manage a certain portion, going over it on an average three times in a fortnight. In particular places we have often found it necessary to machine the grass twice a-week.

In many suburban villas the grass plat in front is often a great eyesore. Many men engaged in business from 9 A.M. to 4 P.M., would do much to keep their little gardens nice, but the grass is a difficulty, as they cannot work a machine well in the morning. In many such cases, it would be far better if the flower-beds were on stone or gravel, as all tidying could be done in the morning or evening. To a certain extent it is well for every one to stick to his occupation, and gardeners should have their appropriate work; but then everybody is supposed to be more or less of a gardener; and it is well that it is so, as whatever pleasure there may be in looking at a garden, that pleasure and interest are easily enhanced when the pleasing effect is at least partly the result of our own labour.

This dry weather has stopped some alterations and turfing operations. That already laid down is standing the weather well; if it should crack at the seams we will scatter some fine soil along them, and then the first rains will make all right. In extreme cases, we have thrown a little soil all over, and swept it off after rain and dryness before the grass grew much. One gentleman is going to a new house in May, and wishes to have a grass plat, but is afraid to venture this season, but would like to set about it if practicable. There is no question as to the practicability, if, as he says, there is no difficulty in procuring the turf. We have laid turf in all the summer months, and for small plots there need be no difficulty, so long as a little extra labour can be given. We would proceed thus—Mow the grass short, whence the turf is to be taken, a few days beforehand, so that the grass shall be growing afresh, and if a shower comes all the better. Then level the plot so as to have all ready for the turf; bring the turf home carefully, and have two tubs if they can be had; fill both with turf, and let it soak in water for a quarter of an hour, and as soon as the first tub is empty fill it again, so that the turf may soak whilst that in the second is

being taken out. Water the ground, if dry, through a rose, before putting the turf on it. Beat and roll in the usual way, and growth will commence at once. We have scarcely ever found more work necessary, except filling up the seams with a little earth if the weather proved very dry after turfing. Thus managed, turf laid in May may be a nice grass plat in June and July. Of course, less labour would be required if the work were done before March, but the above mode may suit some entering on new residences at this season.

KITCHEN GARDEN.

The general operations were very much the same as those detailed in last and previous weeks. Fresh-sown seeds were watered and shaded with a few branches. Ridge and pickling Cucumbers, Vegetable Marrows, &c., were potted off to become established before hardening them off; Tomatoes, &c., were likewise potted and pricked off, Cauliflowers watered, Lettuces pricked off, and arrangements made for pricking out good plants of Celery, and smaller ones to be well shaded and protected. Sowed more Beans in pots to be transplanted, and a lot of Scarlet Runners in boxes to be transplanted, as we think they bear sooner than when sown at once, and can be defended with a few branches before the May frosts are over. We would have liked to have finished our Potato planting, but have been obliged to defer it, to get on with other matters that could not be delayed with propriety.

FRUIT GARDEN.

Out of doors much the same as in previous weeks. In the orchard-house noticed for the first time this season a few of the *brown aphid* (*Aphis persicae*), on a small Peach tree. Put some Quassia chips in a pail, poured some boiling water over them, and covered up with a cloth, as there was a hole in our big kettle, and therefore we could not boil the chips; and about 7 P.M. syringed the tree with the decoction, or tea, at a heat of 130°, repeating the same in the morning at six o'clock. We have seen none of these horrid visitors since, but will keep a sharp look out, as of all insects this is the worst to conquer. We did hope we should never have seen them again, and as yet this is the only instance; but then their powers of reproduction almost exceed belief. We found last year that soft-soap water, and a little of the bitter from Quassia chips, were a very effectual means for giving them their quietus; but the great means of security is to attack them at once, and when one makes its appearance never to wait until a second show itself. The powers of reproduction of the green fly are wonderful—beyond calculation in fact, but are nothing as compared with those of the brown aphid; and, besides, the green fly is a trifle to destroy and eradicate. As yet in these orchard-houses we have seen merely two or three traces of the common green fly; and as the shoots had to be removed in myriads, we took off the few shoots that were affected, and stuck them in our pockets until we had the opportunity of turning these pockets securely out and emptying them in a furnace. If the houses can be kept thoroughly clean by such simple means, it is better in every way than resorting to washings and smokings, which so far affect the plants, whilst they do not always destroy the insects.

As it was possible, however, that in pocketing these twenty or thirty small shoots with fly on them some insects might drop on the wall or the neighbouring shoots, and begin not only their devouring but their propagating functions, we placed a pound of Gishurst, having it by us, and a pound of Quassia chips, in a pail—the Gishurst sliced thin—filled the pail with boiling water, covered it up with several layers of cloth, and allowed the whole to stand ten hours. We then strained the contents of the pail into a barrel of thirty gallons, filled up with water at 125°, and syringed the trees well over. We have not seen a green fly since; but if anything will bring them back this scorching weather, with cold winds, will do so. We have not seen a fly in our early Peach-house as yet, though crammed with Strawberries and many other plants, and we never used the syringe less. The great point of safety as respects insects is to attack them at once—as soon as they show themselves, and not to wait until they take possession and deposit their myriads of eggs. So suddenly do they come, and in such myriads, that there is a little excuse for some otherwise clever men almost believing in spontaneous generation. Just to-day, in a frame of nice healthy Cucumbers, on turning over the leaves a few green fly were seen plastered on the under side of the leaves. Not one was seen until after this dry scorching weather. Whence did they come? This frame had been used for several purposes during the winter. The woodwork inside had been tho-

roughly washed with water as nearly at the boiling point as it could be used. All the woodwork had also been well washed instead of painting with lime and sulphur. Fresh dung and fresh soil had been used—and whence in these circumstances came the little clusters of green fly? There they are, and we know they could only come in the usual way; and the conclusion at which we arrive is, that unless thoroughly crushed it is scarcely possible to destroy the eggs of insects, if they have any access to air when hatching-time comes.

To destroy such insects in frames and pits nothing is more effectual than tobacco smoke. The experienced may use bruised Laurel leaves, or even burn them like tobacco, but they may easily injure the plants by doing so; whilst less care is required in the case of shag tobacco, and the expense of the article will be more apt to guard against its abundant use. In frames and pits there is no better plan than having a hole in the wood or wall, the size of a common cork, through which the funnel of a fumigating bellows or machine may pass, or a pot with a hole in its side may be used, some live cinders put beneath, tobacco or tobacco paper above, and a common bellows' pipe inserted through the hole in the wall, to blow the pot until the place is full of the smoke. If a fumigating machine is used there will be no danger of the smoke being too hot. If a pot and the common bellows are used, plenty of cool damp moss should cover the tobacco, so that the smoke may be cool when it strikes on the plants. Hot tobacco smoke will kill every living vegetable. We are not learned enough to explain the reason, but numerous facts tell us that tobacco smoke is best used when the plants are rather dry and the leaves as dry as possible. When plants are syringed before they are smoked with tobacco the smoke will often be more injurious to the plants than it is to the insects. Experience may thus often be our teacher, though we cannot explain the principles of that experience. Facts tell us that when a house is damp, and the leaves are wet from the syringe or the watering-pot, the nicotine principle of the tobacco, when in the shape of smoke, is peculiarly dangerous, especially to all tender plants: therefore let plants be dry when smoked. In most places it will be economical to have a little box or a small close shed for smoking plants in, as then they can be smoked without tainting the whole house, and a pinch of tobacco will often thus do what pounds would not do in a larger place.

As a case in point, of not being able always to tell how things act, though having no doubt as to the results, we may mention that when the plants were all removed in winter we had a house very much overrun with insects thoroughly washed, walls, woodwork, &c., with very hot soap and water, and then, that every cranny should be reached, we made several little fires in the empty close house, and burned flowers of sulphur and bruised Laurel leaves. We knew that the sulphur would settle every growing thing, though it would not hurt the well-ripened wood of deciduous trees, as Vines, &c., and the result was pretty well what had been desired so far as the destruction of insects was concerned; but what alarmed us was to find, from the moisture used in the house, that the whitish woodwork was almost black from a sulphate and prussiate of lead, whilst our most strenuous efforts by means of brushes, water, and plenty of perseverance were next to totally ineffectual in removing it. Now here again experience became a better teacher to us than our limited science, for when, on repeating such extreme modes of cure, the paint on the woodwork was similarly affected, we just let it alone, and the atmosphere soon restored the colour to the paint, which no scrubbing of ours could accomplish. We will not have discoursed on insects in vain if it impress all beginners with the importance of taking them in time, before an opportunity is given for preparing for successional generations of enemies.

Removed most of the foreright shoots from Peaches, &c., preferring to do this often instead of at once or twice, in order that no check may be given to the growth of the trees. We hope we shall soon have a dull day for Grape-thinning. At present we have to confine such work to the morning and evening. Though the weather has obliged us to use the watering-pot freely, it has saved us trouble and expense in the way of firing, for in such parching weather we prefer in all forcing-houses to give less air and no fire heat during the day. In these sunny windy days it is amazing how little air does when the heating material is cool, and of all heat there is none equal to sun heat. Under such circumstances the little air must be given early, and then the heat from the sun rises gradually, and we would sooner see the houses rise gradually to 90° than give much air when the wind was so parching. Syringing

floors, stages, &c., helped to keep the inside atmosphere in a more genial condition. People, where coal is cheap, need not be so particular, but our impression is that many things even where fuel is plentiful are injured by too much fire heat. Remember that it is scarcely possible to draw or make a plant weak by sun heat if air is given early.

ORNAMENTAL DEPARTMENT.

Much the same as last week. Much time taken up with watering. Plant-houses were shaded by spattering the glass with whitened water, and flooded the floor, and syringed the stages, to keep the atmosphere moist and cool. Filled the frames with the cuttings alluded to last week. Moved all Scarlet Geraniums from the vineries, where the shade would make them weak, and planted great numbers of Calceolarias and Geraniums in "earth-pits," in rows 4 inches or so apart, where they will remain until bedding time, protected with cloth, mats, hurdles, and what we can obtain. The Calceolarias beds were a fine sight before being moved, as in most cases not one in a thousand cuttings had failed, and not a trace of an insect on them. It would never have done to have planted them out finally from such a thicket. We trust in three weeks or a month they will make nice balls for lifting. All these things require care and attention, and must have it to do well.—R. F.

COVENT GARDEN MARKET.—April 23.

A FAIR supply, and great improvement in the quality of many kinds of produce. Kidney Beans are now arriving in considerable quantities along with the other foreign imports, which comprise Asparagus, Artichokes, young Carrots and Turnips, Cardoons, and Green Peas. Dessert Apples and Pears are limited to a few varieties. Good samples of both Ash-leaved and Round Potatoes have come in from the west of England and the Channel Islands.

TRADE CATALOGUE RECEIVED.

James Carter & Co., 237, 238, and 261, High Holborn, London, W.C.—*Gardener's and Farmer's Vade-Mecum. Part III., Store, Greenhouse, and Bedding Plants.*

TO CORRESPONDENTS.

COTTAGE GARDENERS' DICTIONARY (B. W. F.).—Thank you for the slip you enclosed. It is but a hunt on the trail of a red herring. Dr. Hogg never had the slightest pecuniary interest in the "Cottage Gardener's Dictionary," and neither has "his partner," it being, we believe, the property of Mr. H. G. Bohn, or of his successors. The question of its merits is simply one of opinion. On one side there are ranged upwards of 20,000 of the gardening public who have purchased it, and on the other—Who? The writers of the work, as the preface testifies, were James Barnes, of Bicton; Robert Errington, of Onilton; Donald Beaton, of Shrubland; Robert Fish, of Putteridgebury; Thomas Weaver, of Winchester; and Thomas Appleby; and who is their critic? Its price is about 5s., a convenient sum for the light pocket of a young gardener with 12s. a-week, who has not got, and would have some difficulty in finding, nearly seven guineas to purchase as text-books those excellent but expensive works, "The Book of the Garden," "The Theory and Practice of Horticulture," and "The Gardener's Assistant."

ROCKWORK (*A Constant Subscriber*).—No work has been published on this subject. A volume is now going to press on garden plants, fully illustrated, which will contain some examples of rockwork.

STOVE FOR PORTABLE GREENHOUSE.—"C. B." would thank any one who will give information as to the best hot-water apparatus for a portable greenhouse, 20 feet by 12.

DRAINAGE WATER (*Salterton*).—The colouring matter in it is probably vegetable extract, and, if so, would not be injurious to your plants. You could easily determine whether the colouring is caused by oxide of iron. Put a little powdered nut-galls into a glassful of the water. It will strike a black colour if much of the oxide is present.

CALICO SUBSTITUTE FOR GLASS (*E. Gray*).—For your frame proceed as follows:—Old pale linseed oil, 3 pints; sugar of lead (acetate of lead), 1 oz.; white resin, 4 ozs. Grind the acetate with a little of the oil, then add the rest and the resin. Incorporate thoroughly in a large iron pot over a gentle fire; and, with a large brush, apply hot to a fine calico stretched loosely previously, by means of tacks, upon the frame. On the following day it is fit for use, and may be either done over a second time, or tacked on tightly to remain. The quantity made according to this receipt will be sufficient for about 100 square feet of calico.

PLANTING BEDS AND BORDERS (*W. B. H.*).—We cannot do this for you. All that we can do is to correct what we consider wrong in the planting submitted to our judgment.

RIBBON-BORDER (*G. P.*).—We cannot plant; but for colours, say four rows, beginning at the front—1, white; 2, purple; 3, yellow; 4, scarlet. We know nothing of the position or the surroundings.

HORTICULTURAL INVENTION (*Impecunia*).—Not knowing anything of its nature, it is quite impossible for us to offer any suggestion. Implement makers and wireworkers are very different manufacturers.

EPHYPHYLLUM TRUNCATUM (*A. C. C. H.*).—The rooting of your plant from every joint is a sign that it is well, if any, roots in the soil, which has, probably, become sour through imperfect drainage. You will do well to have the plant repotted, removing all the soil from the roots, if any, and using a compost of turfy sandy peat and loam in equal parts, with one-fourth pieces of broken crocks and charcoal, from the size of a hazel nut down to that of a pea, and a free admixture of sand. If the plant have no roots place it deeper in the soil by two or three joints. Water sparingly until new roots are formed, and then give more copious supplies.

PLANTS FOR A SHADY PLACE (*Messeron*).—Few plants will do well in such a situation as you describe. The best plant would be to convert it into a rockery, and grow there the more common kinds of hardy Ferns and alpine. The shrubs that would succeed fairly are—*Aucuba japonica*, *Berberis aquifolium*, *B. repens*, and *B. Darwinii*, *Box*, common and variegated *Hollies*, common *Laurels*, *Cotoneaster microphylla*, *Privet*, *Rhododendron ponticum*, *St. John's Wort*, *Spurge Laurel*, *Snowberry*, *Ivy* of sorts for the walls, and *Periwinkle* to place where nothing else will grow. If you add common *Yew*, *Alexandrian Laurel*, and the common *Butcher's Broom*, you have nearly all the plants or shrubs calculated to grow in your situation.

FRUIT TREES NOT BEARING (*P. C.*).—Your Pear and Cherry trees producing abundance of bloom, but little fruit in proportion, may, probably, be rendered productive by thinning the trusses of bloom. We have found this answer with trees from which we could not obtain nearly the quantity of fruit that we wanted, although they were annually covered with bloom. We simply removed half the blossoms, and this we would advise you to do at once, giving a good watering with liquid manure after setting, and again in July. Mulching the surface with 3 inches of short manure would be advantageous, placing it on the border in autumn and pointing it in in the spring. Try thinning the blossoms.

QUINCE BARKEN (*Idem*).—The Quince is not a shy bearer, and we can only account for its not fruiting by the soil and situation not being suitable. It likes a somewhat moist soil, but not water stagnant in the subsoil. Perhaps your trees are very vigorous; if so, taking them up next autumn and replanting them would check their vigour and induce the formation of fruit-buds. Digging out a trench a yard from the tree all round, and below the roots, would also check vigour, and might induce fruitfulness, the trench being filled in again after cutting all roots thicker than a quill or straw.

WOODLICE IN MELON-PIT (*P. C.*).—Wrap a little dry hay loosely round a boiled Potato and place it in a small flower-pot, lay the pot on its side within the frame at night, and in the morning you will find the woodlice secreted in the hay; shake them out into boiling water. A number of these baits, and perseverance in setting them, will soon clear the pit.

MONOCHETM ENSEIFERUM (*T. E. H. H.*).—We will inquire about this.

COCA-NUT FIBRE REFUSE AS A MULCH (*J. G. H.*).—It is an excellent mulch for Roses if put 2 or 3 inches deep on the surface. It is one of the best retainers of moisture, and, consequently, is a good preventive of mildew on the Rose leaves.

BLACK APHIDES (*R. A. F.*).—After smoking with tobacco, we know of nothing better than soft-soap water, clear, and quassia water, made by boiling 4 ozs. of quassia chips in a gallon of water. See what is said in "Doings of the Last Week" as to using hot water. You must not expect to free your trees of the pest at once.

TANGERINE ORANGE UNFRUITFUL (*Wyeisle*).—We would stop the young shoots, and give the plant all the sun possible.

GRAPE BUNCHES BECOMING TENDRILS (*G. P.*).—The want of a made border, and the want of drainage after such a wet winter and spring, are the causes of your Grape bunches degenerating into tendrils. As palliatives that may answer in the case of your strong-growing Vines, dig a deep drain in front of what you may consider to be the border, and use plenty of fire heat in the autumn to ripen the wood. From such Vines under such circumstances, we have obtained good crops, and especially when the bearing wood was on rods and not spurs. For a thorough remedy the Vines should be lifted in October, and, a good drained border having been made, they should be replanted carefully.

LIUMAGO.—In reply to "A SUFFERER," Mr. Fish says that the band of brown paper round the loins lasts, with him, from one to seven days, according to the work he is engaged in. For instance, on Friday he was thinning Grapes from 4.30 A.M. to 9 A.M., and the paper was reduced to a pulp. When he has been tending and regulating Vines, &c., above his head, the paper would split and creep upwards over the back, instead of over the loins. He is not particular as to the paper: thin or thick, white or brown, the gentle continuous friction is the thing. He uses a light band or belt to keep the paper pretty well in its place. His sufferings on the slightest movement used to be dreadful at times, and all he can say is that since the paper remedy he has suffered next to nothing; and if he goes without for a few days and has a hint of the old enemy coming, a fresh paper stops its advances. The remedy was given to him by three different people who used to be great sufferers, and he will be pleased if by such simple means others should escape such tortures as he endured.

HYACINTHS NOT BLOOMING (*F. G.*).—We think your Hyacinths did root, and have been supported by these roots up to this time. Your deep planting, and very rich soil, added to fresh manure, would be likely to cause the base of the bulbs to damp or decay, the roots perishing. Ours this year have been and are particularly fine, and we first dig the ground as deep as we can, which on our light gravelly soil is not more than 15 inches. We then take up the bulbs, and replant, with the crown 3 inches below the surface, in the first week in October, and in November and not later than the middle of December, mulch the surface with 3 inches of the short litter from a spent Mushroom-bed. This becomes mould by spring, and what there is left is pointed-in in spring, serving to loosen the soil between the rows. These are 9 inches apart every way, with Crocuses of the same colour between, so that we have a line of early and general spring bloom. We merely take up the roots in autumn, remove the offsets, and replant at once. The offsets are planted around three bulbs of blooming size in clumps, and these are not removed annually, but are allowed to grow for two or three years, and then we have fine clumps with a dozen spikes of bloom. Taking up the roots of Hyacinths and other bulbs where the soil is not unsuitable to their growth, is the cause of the diseases which sooner or later seize them, as in the case of the *Tulip* and *Gladiolus* of late in many places. Your Hyacinths seem to have gone off in the same manner, for just when about to bloom they suddenly withered. Do not plant so deeply, 3 or 4 inches will be enough; do not use fresh but well-rotted manure, and none if the soil is in good heart; and place the bulbs with their base on a thin layer of river sand, and cover the crown with the same. Protect from frost by a top-dressing of short litter not more than 3 inches thick, and in spring point it neatly in between the plants. If you follow these recommendations we think you will have a metal bloom.

ALGOSIA METALLICA CULTURE (*S. E. H.*).—Turfy peat and loam in equal parts broken up with the hand two-thirds, well-reduced leaf mould and charcoal broken to the size of a pea and not larger than a hazel nut in equal parts one-third, along with one-sixth of silver sand, make a compost that suits this plant well. The drainage must be good, and there should be a thin layer of moss or the most fibrous parts of the compost over it. It will do with a shift from a 6 to a 9-inch, or from a 9 into a 12-inch pot. In potting be careful to preserve the thick fleshy roots, and keep the base of the bulb-like part rather high. When growing it requires abundance of water, and should have a very humid atmosphere. This, however, should not be created by constantly syringing the foliage, which, as you conjecture, is impatient of that. The cause of the leaf set being scorched was the sun shining on water standing upon it. Shade should be given from bright sun from the end of March to October. A temperature requires plenty of room, and to be kept near the glass. A thermometer from 70° to 75° by night is essential, and the thermometer may rise to 90° by day in summer; in winter the plant will do in a temperature of from 60° to 65°. It should not be very firmly potted; the soil should be left free, but not too open.

NAMES OF PLANTS (*Lachenalia*).—The Fern is *Pellaea adiantifolia*. The Primulas are not superior, though good. (*A. E. E. B.*)—1, *Polystichum aculeatum*; 2, *Lastrea dilatata*. (*D. G.*)—*Dondia epipactis*. (*Prospero*).—The specimen sent was insufficient for determination. (*F. T. P.*)—*Scolopendrium vulgare* var. *cristatum*. (*G. R. C.*)—1, *Scolopendrium vulgare*; 2, *Pellaea adiantifolia*, probably. (*G. N.*)—Specimens very incomplete. 1, *Lastrea* sp.; 2, *Pteris longifolia*; 4, *Lastrea Filix-mas*; 6, *Polystichum aculeatum*; 7, *Zamia* sp., probably *Z. pumila*. (*H. H.*)—11, *Leptostichon scoparium*; 12, *Rivina lavis*; 13, *Clerodendron fragrans flore pleno*; 14, *Cyrtanthera Polliana*; 15, *Maranta bicolor*; 17, *Eranthemum vertovsum*; 18, *Amaryllis Johnsoni*; 19, *A. formosissima*; 20, *Brygmansia sanguinea*; 21, *Coleonema alba*; 23, *Cantua baxifolia*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 28th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RAILWAY CHARGES FOR POULTRY.

The following is a copy of the memorial sent by the Poultry Club to the Directors of various railways. We hope it will be sustained by other memorials, for the greater the number the more likely is the object to be attained:—

"The breeders and exhibitors of poultry whose names are herewith attached, being members of the Poultry Club resident in different parts of the kingdom, beg respectfully to call the attention of your Board to the grievances under which they labour. The high rates chargeable for carriage on poultry going to or coming from agricultural meetings and poultry shows are felt by them as a serious obstacle to the extension of such exhibitions. In many cases exhibitors living at the extreme ends of the kingdom, and even those not very far distant from the shows, are deterred from sending their poultry by the high charges made for carriage. They would respectfully suggest either of the following plans for the consideration of the Directors, as meeting their wants and tending to increase traffic, both of poultry and visitors, to shows throughout the kingdom, either—

"First, To permit such packages to be sent to shows at the usual full rates, and to be returned, when unsold, free of charge;

"Second, To allow them to go and return at half the usual rates when unsold;

"Third, To carry all poultry to and from every show at van-
parcels rate, but by express or passenger trains;

"Fourth, To adopt a uniform rate of one halfpenny per pound for the first hundred miles, and one farthing per pound for each hundred miles after, for conveyance by express or passenger train. The two latter would be, probably, the most easy to accomplish, as they would not interfere with general arrangements, and would be a great boon to your memorialists.

"The objections to sending by slow or luggage trains are, that the poultry would be so long on the road, and it is of the utmost importance that they should be delivered with the greatest dispatch at their destinations.

"Your memorialists would call special attention to the anomalous and uncertain nature of the charges made, wide differences often occurring between the outward and homeward charge on the same package, as well as in the rate of charge from different stations, thus debarring your memorialists from making any calculation as to the probable end of their expenses when entering their specimens for exhibition.

"Your memorialists hope that, considering the national importance that poultry-breeding is assuming in the present time of scarcity of animal food, the amount of traffic which such exhibitions promote upon your lines, and the probable increase both of the pens exhibited and of the exhibitions, you will take their case into your favourable consideration." [Here follow the names of the members.]

My notice last week relative to this subject promised the concluding list in the course of a few weeks. Since sending the same to "our Editors" circumstances have taken place which induce me to alter my determination. The facts are simply these: It will be in the recollection of the readers of "our Journal," that in my first papers on this subject I urged the propriety of the Poultry Club taking this matter up, and Mr. Tudman brought the matter before the meeting at Rochdale. Though absent I was his supporter on that occasion, but I also urged a memorial independent of the Club; but I think all must have understood that I meant our memorial to be in support of that of the Club, not to cut away the ground from it, and certainly in no spirit of opposition—this, indeed, would have been utter folly. To this end I entered into communication with the Secretary of the Club, asking him to sign, and begging him, as I could not be at Rochdale, to procure me some signatures to the independent memorial. To this I received no reply, and on a second appeal I found that the Secretary did not like to have his name appended to two memorials. I then asked what the Poultry Club intended to propose to the railway companies, that we might ask the same, and strive for the same end. The reply said that the memorial would soon be completed, and that I should hear further shortly. Accordingly, last week I had a few lines to say that the memorial would be published on Saturday the 21st! I was not prepared for this, and I can hardly gather whether the memo-

rial has been presented or not; but I feel that if it have ours ought immediately to follow. Accordingly, I propose to have the following lithographed, with the names of those who have permitted me to sign their names attached to it, and to forward the same as soon as possible to the head-quarters of the various companies. This is not exactly the plan I wished to adopt, but I am willing to sink any minor differences. I feel that the signatures appended to our memorial are well known in the poultry world, and must carry some weight; so we must launch our venture and hope for the best. We will wish the Poultry Club all success in their effort.

"Gentlemen,—The breeders and exhibitors of poultry whose names are attached to this memorial beg respectfully to draw your attention to the hardships they have to complain of. Poultry exhibitions are now very general over the country. Their establishment has materially increased the passenger traffic and added to the revenue of railways, whilst the exhibitors themselves, in the support of the various exhibitions, have already heavy expenses to bear. The varied rates for the carriage of the baskets, the different rates charged for the same hampers on the same journey, the delay that frequently arises in transit,—all tend to disgust exhibitors, and lessen the number both of exhibitions and entries. Your memorialists are aware that the National Poultry Club have forwarded you a memorial on this subject; and as they agree with the tenor of that memorial, they trust that your Board will favourably consider the subject and give them some relief.

"Your memorialists beg respectfully to suggest that a moderate rate, the same on all lines throughout the country, would best meet the difficulties of the case; but either the third or fourth proposition of the Poultry Club would be a great boon, and would be gratefully appreciated by all those who are interested in the welfare and stability of these exhibitions.—We are, &c."

I intend to enclose with this a note from myself, stating that the documents authorising the appending of these signatures are in my possession.

There will probably be time for other names to be added if any other exhibitors choose to write me. I have heard in the affirmative from

Mrs. Hayne, 1st. 6d.

Mr. J. J. Fox.

Mr. T. Walmesley, 10^s. 6d.

Mr. E. Sherman, 5^s. paid.

Mr. F. Parlett, 5^s. paid.

Mr. E. Hutton.

Mr. J. R. Jessop, 5^s. paid.

—JOSEPH HIXTON (Y. B. A. Z.), *Hinton, near Bath.*

HOUDAN, LA FLÈCHE, AND CRÈVE CŒUR FOWLS.

As I have imported some very choice specimens of La Flèche, Crève Cœur, and Houdan fowls, I am much interested by your mention of those breeds in your article on "Comparative Healthiness." I find, with you, that the Houdan are certainly the most hardy, and thrive excellently in confinement, and mine are now laying at the rate of six eggs in seven days. The La Flèche have also rapidly acclimatised themselves, and with me the Crève Cœur have proved the most delicate.

You may be interested to know that a sitting of Houdan eggs that I put under a hen some days ago weighed 29½ ozs. troy, the four largest being short of 2½ ozs. each, respectively 8, 49, 66, and 83 grains. I fancy few English breeds lay such fine eggs.—A. H. S. W.

[The weight of the eggs is much less than that of the Spanish, whose eggs average 3½ ozs.—EDS.]

BEWARE OF PICK-BOXES.

It is not Reynard, the fox, that, as he does on the Continent, thins a poultry-yard in England—he is too well taken care of, and is seldom obliged to eke out his breakfast with a young chicken—neither is it the marten, nor the cat, nor the roop, that is most to be feared. In all these cases prevention is not quite out of the question; but, when the birds disappear from the hamper or the box whilst left at the mercy of "queer frequenters" of railway stations, then it is that safety becomes quite a matter of chance.

In the first week in April I received a box from the Continent, that ought to have contained five pairs of Pigeons, but there were only four; and an almost irreparable loss, the only pair of the rarest of crested yellow Tumblers, was conspicuous by its absence. The thief must have had ample time to forcibly

pick his way through the wooden bars that let the air in from the top, and to tastefully select just the only pair of Pigeons, that even Mr. Brent in his book believes to be almost of fabulous origin. However, the unknown connoisseur did not stop there. During the second week another box arrived, which ought to have contained eight pairs of Pigeons, chiefly Hungarians and Siberian Ice Pigeons; but in reality there were no more than fifteen birds, one Siberian Ice Pigeon having taken flight through the oak boards of the box, as I am led to believe. Question, On which company to fix a claim for compensation? The journey extended over six or seven different railways, foreign and English, the birds having originally been entrusted, and complete in number, to a royal post office. I suppose I have to confine myself to grumbling, and to find consolation in the well-known phrase "There is no help for it" Therefore, now, when the gathering of the winged clans will commence, exhibitors beware of "nimble hands;" they are more real than those which the Brothers Davenport ever made appear in the window of their magic closet.

The purpose of this communication, however, is not merely to serve as a caution for the benefit of Pigeon fanciers, like myself, but the motive is rather a selfish one, and shortly this: I am, to the best of my belief, at present the only possessor of Siberian Ice Pigeons in England, and I am equally sure that nobody else has imported crested Pigeons of the variety named, and, therefore, I should feel exceedingly obliged if managers of Pigeon shows would kindly communicate with me as soon as any other person may enter for exhibition birds answering to the names given.—FRANCIS BRÖGEMEL, 2, Church Grove, Ladywell, Kent.

BEEES IN THE HOLY LAND.

My attention has been drawn to a note in your impression of the 10th ult., by "A DEVONSHIRE BEE-KEEPER," correcting a statement in my volume, "The Land of Israel," that the bee of Palestine is *Apis ligustica*.

I did not make the statement without the authority of eminent naturalists, and in support of the opinion that *A. ligustica* and *A. fasciata* are identical, I beg to forward the following extract from a letter of Mr. Frederick Smith, of the British Museum:—"The authority on which *Apis fasciata* is considered to be identical with *A. ligustica* is that of Gerstäcker, who has reduced the number of honey-bees of the genus *Apis* to four. I have published my own opinion in the 'Transactions of the Entomological Society,' and have more material in hand on the subject which I hope to publish shortly." There cannot be much higher authority than Mr. F. Smith.

Though I have reserved the details of the fauna of Palestine for my forthcoming work, under the auspices of the Ray Society, I have been careful in "The Land of Israel" never to introduce scientific names without the best authority within my reach. Your correspondent has rightly corrected me about the yellow bands on the thorax, but the antennæ do appear to me on comparison longer proportionally than those of *Apis mellifica*.—H. B. TRISTRAM, Greatham Vicarage, Stockton-on-Tees.

[As I most cordially indorse the opinion advanced by Mr. Tristram that "there cannot be much higher authority than Mr. F. Smith," I imagine he will at once accept the following passage, which I quote from a letter just received by me from that gentleman, as conclusively settling the point at issue between us.

"Since I published my paper, you sent me such material as at once settled the question of *A. fasciata* being abundantly distinct. . . . I certainly could not reject Gerstäcker's opinion eighteen months ago, but I am in a very different position now, and I am quite as satisfied that *A. fasciata* is distinct from *A. ligustica* as a species as I am of *A. dorsata* being distinct from *A. mellifica*."

I may state in elucidation of this last sentence that *A. dorsata* is the large and beautiful honey bee of the tropics, which, in point of size and brilliancy of colouring, may well rival our English hornet. The difference between this magnificent *Apis* and the ordinary English honey bee, *A. mellifica*, is, of course, so great that they may be deemed "wide as the poles asunder."

Dr. Gerstäcker himself declares that *Apis fasciata* is the form of honey bee "which is most distinguished from all others by its smaller size and light colour," and although he afterwards states that "the identity of the Italian with the northern bee

is demonstrated by the perfect mutual fertility of the two forms, and the African form approaches much more closely to the Italian than the latter does to the northern bee," he separately mentions *A. fasciata* and *A. ligustica* as two out of the six principal varieties which he enumerates as being comprised in one of the three perfectly distinct species into which he considers the genus *Apis* should be divided. If, therefore, the idea originated that this distinguished German naturalist declares these two varieties to be absolutely identical I am perfectly unable to discover.

With regard to the supposed "very long antennæ" of *A. fasciata*, I have carefully compared the antennæ of this species with those of both *A. ligustica* and *A. mellifica*, and find that there is really no difference whatever in their length.—A DEVONSHIRE BEE-KEEPER.]

FERTILE WORKERS.

EARLY this month (April), I missed a Ligurian queen which I had placed at the head of a stock of common bees driven from a cottager's hive last autumn. Notwithstanding her apparent absence, there were a great number of eggs deposited with the utmost regularity in the cells of one of the worker-combs, the presence of which caused me many unavailing searches after the missing sovereign. At the expiration of ten days, however, all doubts were set at rest by the discovery that the cells occupied in this manner were being elongated for the accommodation of drone larvæ. Finding, therefore, that the hive was indeed queenless, I speedily united the remaining bees to the stock which stood next to it, but deem the case worth notice as an unquestionable instance of the existence of fertile workers.—A DEVONSHIRE BEE-KEEPER.

NEVER DESPAIR.

FOR the encouragement of those inclined to despair when a calamity of any sort befalls their bees I write these lines. During the heavy gales of last November one of my strongest stocks was capsized. Those who love their bees may imagine my surprise and horror. I was, as it were, thunderstruck and helpless. There lay my splendid stock prostrate on the ground, and I felt at the moment more inclined to rush from the garden and leave the hive to its fate, than to do anything else. Shame and remorse, however, for such a feeling soon rallied me, and calling my man to my assistance, we set to work to replace the hive on its stand. When this was accomplished the honey poured out in streams, and with it the bodies of many beehind and half-smothered bees. I found then that the only thing I could do was to raise the hive an inch from the floor-board all round, by this means giving free egress for the honey, and, above all, giving the bees an opportunity of collecting at the top of the hive where they might clean themselves, and be free from the broken combs. Having put saucers to catch the running honey, I, with a low heart, left them till the next morning. When I then went to them I found all the honey had run from the broken combs, and so, gently raising the hive, I discovered, to my delight, the bees that were alive all collected in a bunch at the top, and quiet. This gave me hope that the queen had escaped with her life, and so it has proved.

The stock I write of was a last year's swarm, at least it was two swarms joined, and, consequently, they were very strong; but, curiously enough, they had begun working on the floor-board, so that when I raised the hive there stood the combs, except those parts that were broken, erect on the board, and hardly a bit of comb left in the hive. I determined if possible to save the stock; so giving them a fresh floor-board, I put them on it, set them in their place, filled a super with about 10 lbs. of their honeycomb, and gave it them on the top of the hive, did them up for the winter, and left them to their fate. On the 1st of February I examined them, found them alive and well; gave them some more honey, as they had nearly consumed the 10 lbs., and now they are working hard making comb, and giving every promise of doing well.

The weight of honey taken from the hive was 34 lbs. The bees are in a wooden hive with a large glass window, and a hole at the top for supering. Through the window I can see the progress they are making with their comb, and as soon as they can rear a few young bees, no doubt the work will proceed more rapidly, and the hive will soon be filled.

These particulars may interest some, therefore I give them; for I do not imagine that the tenants of many hives in bee-history have escaped with their lives when they have had the misfortune to meet with such an accident as that which I relate.

As I am writing on bees, I will just mention my last year's success. I commenced the year with four stocks, and from these I had seven swarms, and took in supers, and from the hive that was blown down, 128 lbs. of virgin honey.—A GLOUCESTERSHIRE BEE-KEEPER.

IS THE TOMTIT AN ENEMY OF BEES?

Noticing the reply to "A SUBSCRIBER" in page 282, I wish to raise the question whether the tomtit, *alias* the "Hampshire bee-biter," is the friend of the apiary or its foe. I am inclined to believe he is only a scavenger, never having seen him seize a bee in an active state. When hibernated by cold, or paralysed upon the snow, the unfortunate bees in such circumstances afford him a rich repast; but then this is just as it should be. In any case the bees would be lost if the bee-master failed to collect and cherish them.—R. S.

IMPROVED FRAME-HIVE.

In reference to the remarks under the above heading, in page 300, allow me to state that the alteration there referred to will not be found the least troublesome, even by those who have adopted "another pattern." It never ought to be necessary for the front of any kind of hive to fit closely to the front of any bee-house. I invariably allow certainly not less than 2 or 3 inches space, which allows a free current of air to pass all round the hives, materially assisting the ventilation, and preventing the bees feeling the effects of a hot summer's sun playing upon the front of the bee-house.

Many bee-keepers have experienced the difficulty of loosening and lifting out the frames with the finger and thumb, which is obviated by the bars projecting through the back and front of the hive. The ends of the projecting bars can be held by both hands, and if the bar is placed at the proper distance from the front of the bee-house, there can be no difficulty whatever in manipulating.

It is true that when the top bar was cut through the solid wood, the divisions sometimes broke quite away, thereby causing great inconvenience and trouble; but this is entirely obviated by the use of Pettitt's patent metallic bar rest, as mentioned at page 266. These rests are made on the seven-eighths or Woodbury scale, the one-inch scale, and the 1½-inch, or Langstroth scale, and can be adapted to any frame (a Woodbury frame for instance), by the addition of a top bar of the required length, which can be attached to a Woodbury frame with a couple of screws, without in the least interfering with its present construction.—WYATT J. PETTITT, *The Apiary, Dorset.*

OUR LETTER BOX.

DORKING COCKFEET, WITH DISEASED HEAD (F. H.).—Bleeding in the foot was a mistake, and we imagine was carried to excess from the look of the comb, which was blanched as much as if the bird had had its throat cut. Bleeding should only be resorted to where there is giddiness and staggering, and then it should be from the comb, which in these cases is dark and lead coloured. An egg-spoonful is enough to take. The eyes were gone, in a manner we have never before seen in a Dorking. This is a disease almost peculiar to Spanish, and near-by. We do not know the origin of it, and there is no treatment for it. It is not, however, likely to occur again. The brain was quite healthy.

ARTIFICIAL INCUBATION FAILING (G. M. F.).—There is little doubt but that the temperature of your incubator fell too low, and the chickens died. The water in which you try your eggs need not be at 105°, all that is necessary is that it should be warm.

DORKING CHICKENS' FEET DISEASED (J. L. B.).—Such a complaint as you describe will arise from bad flooring, such as stone, brick, or wood. This induces paralysis, and causes death. We always look with suspicion when we find our correspondents talk of keeping the "chickens warm." All the warmth they require they should get from food, and if they are free from draughts, that is almost all the shelter necessary. Put the hen out of doors under her rip with the chickens, and feed them well. They will then recover from all their ailments.

NON-SITTING FOWLS FOR A CLAY SOIL (J. T. F. R.).—If you pin your faith to non-sitters, you must have Spanish; but we think you might keep Brahmas more advantageously. We do not think your cross would be a good one. You fear roup, and Hamburgs are subject to it. We have kept Brahmas twelve years and never had a case of roup.

DUCKLING LAME (J. R. B.).—Your Ducklings are perishing from being uncared for while too young to shift for themselves. You should have confined the hen where she could not have roosted. We fear all the brood will die.

FOWLS FOR A CONFINED SPACE (A. J.).—Spanish, Brahmas, and Cochins will all do in such a space as you describe. A cock is not necessary for the production of eggs.

BUFF COCHINS (N.).—We hardly know what you mean by fine eggs; but Cochins never lay large ones. It is certain that May pullets ought to have reared chickens and laid again before now. We believe you will make a very good hardy fowl by the cross you mention. Choose your pullets with white, clean legs.

DUCKS HATCHED UNDER A HEN (B. K. H.).—Yes, beyond a doubt they are good for stock. Assertions to the contrary are nonsense.

HENS EATING EGGS (E. H.).—There is no doubt it arises from a disordered state of body. It is fortunately an uncommon occurrence, but we fear those that begin seldom leave it off. In all cases of egg-eating we advise placing hard composition eggs under the culprits, they peck at them till their beaks are sore, and they are tired. They then give up the job in despair.

GESE EATING THEIR EGGS—HAMBURGS LOSING TAIL FEATHERS (F. B.).—Geese, like other poultry, eat their eggs sometimes. All poultry also nibble their eggs. We always feel disposed to laugh or question when people declare so freely that "no hen could sit better or closer." It is very often the case that she sits well for forty-eight hours, till a germ is developed, then she leaves fill the eggs are cold, and then really does sit closely. These eggs are spoiled. She is eating the Duck's eggs. If the hens lose their tail feathers it is probable that the places in which they lay are too small for them, and the feathers get broken. It is a serious disadvantage in some breeds for a cock to lose his sickle feathers, especially in Game and Cochins. If the stumps be pulled out, the feather will grow again in about ten weeks; if there is not time for them to grow again, it is better to leave the stumps in than to pull them out. The growth of the tail is considered to be a greater effort than making any other part of the plumage, but it is not injurious.

CAUAGA DUCKS (H. C. P.).—The account of these Ducks we extracted from one of the American journals. They could be obtained, we have no doubt, by application to a friend at Boston, or Chicago. We shall be obliged by being informed where they can be obtained.

BEES CEASED FROM WORKING (A Lady Bee-keeper).—The queen bee which accompanied your note was alive when she reached us. We warned and fed her, and, when somewhat revived, introduced her to a queenless colony where she seemed well received, but was too far gone to recover, being cast out dead in about an hour. We then dissected her, and found her perfectly fertile. She was, in fact, a very fine queen, and we doubt not quite capable of keeping up the population of a strong colony. The nymphs contained in the five cells which were sent with the queen were those of workers.

CLEANING FLOOR-BOARD OF HIVE (G. W.).—If your bees are healthy and strong they have probably cleared out their hives ere this, and it would, therefore, now be useless to meddle with them. The floor-boards of weak stocks may, however, still be cleaned with advantage. The white specks on the floor near the hive's entrance you mention are probably the waxen covers of the honey cells which, during winter, have been gnawed off by the bees; or, if comb-building is going on, they may be newly secreted scales of wax, many of which are at such times dropped by the little artificers.

CREAM CHEESE (Kate).—Hang the quantity of cream to be made in a wet cloth in a cool place for six or seven days, which will depend upon the weather and the state of the cream. Put it into a mould lined with a cloth; put on the press with a light weight; turn it twice a day, and it will be fit for use in a short time. Roberts on "Wine Making" will suit you, and so will Ward's "World in its Workshops."

AQUARIUM REQUISITES (Julia M.).—Apply to Mr. King, Naturalist, Great Portland Street, London.

BREEDING PIED GOLDFINCH MULES (A Novice).—Pied Goldfinch Mules are bred from hen Canaries reared on purpose. They are bred from Pied birds, and in-and-in-bred to make them break in colour. Instances are on record of Goldfinch Mules breeding, but they are so rare that they can only be regarded as the exception to the rule that Mules do not breed. Your food for young Goldfinches is good if you do not use much hempseed; rape would be better if well scalded, and washed to remove its pumpancy. I think the reason of their dying is apoplexy, they being too fat, owing to the egg and hempseed being too stimulating a diet. Death seems to occur after they have completed their plumage, when the drain on the system owing to growth and plumage-making is at an end. Bird organs may be purchased of most London dealers.—E. P. BRENT.

HAND-REARING YOUNG BLACKBIRDS AND THRUSHES (C. Sedgely).—Feed the nestlings on ground oats and sharps mixed with milk, and with a flattened stick feed them every two hours as long as they will open their mouths. Keep them very clean, and you will be rewarded by fine, large, healthy birds. Sharps, I think, is sold in London under the name of toppings of Indist.—E. P. B.

BOOKS TO AMERICA (J. P. Clark).—The bill of exchange was duly received, and the books sent as you desired to the Liverpool firm, on the 15th of February. There is no safer way of sending money than as you did.

POULTRY MARKET.—APRIL 30.

The supply is moderate, but the trade is unusually dull, and there is little demand.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 62.5°; and its night temperature 40.1°. The greatest heat was 81°, on the 12th, 1833; and the lowest cold 21°, on the 8th, 1855. The greatest fall of rain was 1.14 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

CINERARIA CULTURE.

DWARF and compact in growth, profuse in foliage and bloom, and withal of easy culture. Cinerarias are general favourites. They are raised from seed, and the

named sorts and desirable seedlings propagated by offsets.

FROM SEED.—Good seed, and saved from the finest flowers only, should be sown. Cheap seed is not worth sowing, let alone the trouble of rearing and growing the plants from it. For plants for autumn bloom the seed should be sown in the beginning of March in pans drained to one-third their depth with broken pots, some large pieces being placed over the holes, some smaller ones above them, and then half an inch or so of the siftings of the compost, which may consist of turfy loam two-thirds, and leaf mould one-third, adding one-sixth of silver sand. With this compost fill the pan to the rim; then take a flower-pot, and pat the surface of the pan gently with the bottom of the pot. This will lower the soil half an inch or so, and make the surface quite smooth. Now scatter the seeds thinly (half an inch apart) over the soil, just cover them with finely-sifted soil, give a gentle watering, and place the pans in a frame where there is a bottom heat of 70° and a top heat of from 55 to 60°. Keep the soil just moist, and immediately the plants appear place them within a foot of the glass, for they must not be allowed to become drawn. A gentle sprinkling of water from a fine-rosed watering-pot or syringe in the morning will generally keep the soil sufficiently moist; but whether that is the case or not the soil is never to be allowed to become thoroughly dry.

After the plants are up, and the rough leaves appear, give air whenever the weather is mild, and harden off gradually, so that they will bear potting when sufficiently large to handle. Pot them singly in three-inch pots, using the same compost as in sowing the seed; place them in a frame with a gentle heat, and keep close and shaded for a few days, sprinkling them overhead in the morning. Keep them thus until they begin to grow, then gradually harden them off, and place them in a cold frame with the pots set on coal ashes, or, whilst the plants are small, let the pots stand on those to be used at the next shift, so as to bring the plants nearer the glass. Give abundance of air, and draw down the lights whenever the weather is mild and showery, but keep them on during dry hot weather, and when heavy rains occur; then tilt the sashes, for abundance of air and light are the essentials to success. Never allow the plants to suffer from want of water, but keep the soil moist, yet let moisture be needed before it is given. Preserve a moist atmosphere by sprinkling water overhead morning and evening, and especially in the evenings of hot days.

Under the above treatment the plants will grow well, and must have a shift when the pots are full of roots, and before the latter become matted so as to resemble muslin. Shift the plants into 4½-inch pots, then into 6-inch pots, and when these become full of roots select the best plants, and place them in 8-inch pots. In all cases the drainage must be good, and consist of one large crock over the hole, two or three of good size above that, and then from half an inch to an inch of smaller ones, and over these again an inch or so of the rougher parts of the compost. The smaller plants may remain in 6-inch pots, and though not so large they will be none the less useful on that account. The compost to be preferred is that from turves cut 2 inches thick, and laid up in alternate layers with fresh cowdung from the fields, an inch of this between every layer of sods. This compost laid up for six months, then turned over, and again turned at the end of three months, will in three months more be fit to be chopped up with a spade, and placed under cover. When it is neither wet nor dry add to it one-fourth of leaf mould three-parts reduced, and one-sixth of silver sand; and this compost, well mixed together and incorporated, will grow Cinerarias to perfection. Chop up the compost with a spade, and break it as fine as you like with the hand, but no sifting is to be allowed. Pot firmly, but not very tightly. If the plants are to be well watered the soil should not be soddened with moisture, and if they are not to become pot-bound they must not be repotted until the pots they are in become filled with roots, nor should too large a shift be given.

After June use the lights only during windy and very wet or dry weather, and when kept on tilt them, at the same time elevating the frame on bricks laid flat at each corner. Thus the air will play all round the plants, and air, coolness, and moisture are their delight.

After the last potting, when the roots reach the sides of the pots, water once a-week with liquid manure, and when the plants show for bloom give a weak application twice a-week. Keep them in frames as long as possible, and then remove them to a light airy situation in a house having a temperature of 50°, and they will be fine when bloom is becoming scarce.

For the general spring bloom seeds should be sown from the middle of May to the end of June, the plants blooming early or late according to the time of sowing. If sown in May the pan should be placed in a gentle hotbed until the plants appear, and when hardened off these should be removed to a cold frame; but if not sown until an advanced period in June it will suffice if the pan be placed in a frame kept close. The above directions as to potting off and repotting the plants are equally applicable to these sowings; and though they are later, they will produce the finest plants. By October these will have splendid foliage, and if sown in May will be in their last pot but one—viz., a six-inch pot. So long as the weather continues mild they could not have a better situation than a cold frame; but nuts or other material for covering must be in readiness to protect them on frosty nights. When they can no longer be kept in frames on account of the frost and damp, remove them to a cool house with a temperature of from 40°

to 45° from fire heat, and put them as far from the heating apparatus and as near the glass as possible, and where the air is admitted into the house. Air must be given whenever the weather is mild. If the plants are kept near the heated surface the air is too dry for them, and aphid is the consequence; if they are not near the glass they become drawn, and if they are not afforded enough of air they will mildew, damp-off, grow lank, and flag with the first gleam of sunshine.

By the middle of October the plants in six-inch pots which have filled these with roots should have their blooming pots, and this refers to the earliest sown. Eight-inch pots are a good size, and large enough for plants to bloom in, as these will, in February or March. Those in smaller pots should have a shift, say from 4½ to 6-inch pots, in October; in December they will need 8-inch pots, which they will fill by the end of January, and they may then have 10-inch pots, which are large enough. In this way they are to be grown on until they are placed in their blooming pots, and when these become full of roots liquid manure once or twice a-week is applied instead of affording another shift.

Seed may also be sown in August for late-blooming plants. From the time they make their appearance the seedlings are never allowed to stand still. They are potted off, repotted, and all the while kept growing slowly up to the time of blooming, and that is the grand secret in growing *Cinerarias*.

FROM OUTSETS OR SUCKERS.—When the plants have done blooming the flower-stems should be cut away to within an inch or two of the soil, and they should then be placed in a frame and fumigated with tobacco, as there is generally plenty of aphid. The frame being kept close and moist, suckers will be freely produced; when they appear give abundance of air until they are of a size fit for potting, then pot them directly into small pots, and keep them close and shaded until established, afterwards admit air, and treat them in the same manner as seedlings, only they will not grow so rapidly, and will never be so robust. The first suckers may be taken off in June, or early in July, and these, potted then in three-inch pots, will require a shift in six weeks, another shift six weeks later, and by October they will be in six-inch pots, and be ready for shifting into their blooming pots. These plants will flower early. For general spring-bloom, plants are obtained from suckers taken off in August from plants which after blooming were turned out into the open ground, in a moist, shady situation. Such suckers are to be potted and placed in a frame, kept close and moist until established, then hardened off, and the lights drawn off whenever the weather is mild, and kept over them tilted when it is very wet, or dry and hot. They must be potted on as they require it, and they will need a shift early in September, which should be into pots 4½ inches in diameter. If the lights over them are tilted day and night, the plants will grow strong and stocky, and will not be so apt to run as those exposed to all weathers. In the evening a sprinkling of water resembling a slight shower will do them good. Keep the soil moist, and do not allow them to stand too close together, allow room between each for light and air. Continue them in the frame until the nights become cold, and the air damp, then remove them to the lightest and most airy situation which the greenhouse affords; placing them on a shelf so as to be about a foot from the glass is best. This will be towards the end of October, and as the atmosphere of greenhouses is often much drier than that of frames and pits, a gentle bedewing of the foliage in the mornings of bright days will be of advantage; but unless the day be such that air can be given, it must be omitted.

If there is the convenience of a pit affording accommodation for the plants at 1 foot from the glass, and provided with means for air being given whenever the external temperature exceeds 55°, and having a hot-water pipe or two in front to keep the temperature from falling below 55°, and also to promote a circulation of air in dull, damp weather, that is the most suitable place of all for *Cinerarias*.

The plants should have a shift prior to being removed from the frames to the greenhouse, or if kept in pits, the second shift is to be given in the second week in October, always bearing in mind that they are not to be shifted into larger pots until those in which they are at the time are full of roots. The plants will run for flower, and as it is not desirable to have them all alike, the points may be taken out at the third joint, though some plants may be left unstopped, and will have all the flowers on a single stem. The stopping will induce side shoots, three or more, and as these grow the large leaves should be pegged down, so as to keep the centre of the plants clear, which will cause the shoots resulting from stopping to become

strong. Be careful not to over-water, and be very particular not to allow the plants to suffer from dryness, or the loss of the best leaves will be the consequence. When the shoots have made four joints peg them down, and take out their points above the fourth leaf of the last growth; by this time they will require eight inch pots, and that will be early in January. The plants will now grow rapidly, and if the shoots still come strong and make three joints without flower showing in the axils of the leaves, and the pots are full of roots, shift into 11-inch pots, pegging down the shoots towards the sides of the pot, but not so as to break them, and take out their points at the third joint.

If the plants are required to be grown in eight-inch pots, and if the shoots produced are still strong, and do not show for bloom, they may be stopped at the third joint, pegging or tying them down as in the case of those potted into larger pots, and water once a-week with weak liquid manure. Should the plants show for bloom, the shoots must not be stopped, but be tied out to neat deal stakes painted green, and remember that the shoots must not be huddled together or two tied to one stake, but so distribute the stakes that every stem shall be so far from its neighbour as to allow of each displaying its head of bloom; and aim at a close, flat head, and yet not so close as to have some flowers hiding more than those seen. Allow room enough, so that the plants may have light and air on every side, and turn them round frequently, if inclined to become lop-sided, for nothing is more ugly in a *Cineraria*. The plants stopped should be staked out, stopping ought to be discontinued, and regulating and tying out the shoots must be attended to frequently.

When the pots become full of roots, water once a-week with liquid manure, and as the plants advance for blooming it may be given at every alternate watering, until the flowers have for the most part fully expanded, when water only is best. Towards blooming a slight shade from bright sun is advantageous, and the beauty of the plants when in bloom will be much prolonged if the roof be shaded from sun by a covering of tiffany; they should also be well attended to as regards watering.

Suckers taken off in September will make small plants for blooming in April, and larger ones may be obtained by stopping them up to March, and shifting them in the first week of that month into their blooming pots. The latter will bloom in May and June. The temperature for growing plants should never exceed 45° from fire heat, and to grow them slowly it should be from 40° to 45°. They will sustain no injury in a temperature as low as 35°. For plants coming into flower a temperature of 50°, and not exceeding 55° from fire heat, is essential. Air, whenever the external air will permit of its being given, cannot be too liberally afforded, nor can they be kept too cool if only protected from frost. If allowed to become pot-bound they start for bloom, and then specimens cannot be expected. Moisture with air they flourish in; but a moist stagnant atmosphere brings mildew and aphid, and a dry atmosphere, even with air, causes the leaves to curl through the attacks of aphides; and if dry from fire heat thrips appear on the scene. If the plants suffer from want of water the foliage becomes miserably poor.

INSECTS.—Green fly is the most troublesome. The house, pit, or frame should be smoked with tobacco whenever an insect is seen, taking care to let the smoke reach the plants cool, and to have their foliage dry. It is a good plan to fumigate every fortnight by way of precaution, and even if this be done once a-week it will not be labour in vain. Should the plants become much infested, smoke on two consecutive evenings, and syringe the plants in the morning forcibly, but not so as to break the leaves, laying the pots on their sides and then turning the plants so as to give a thorough cleansing. Thrips are to be dealt with in the same manner.

Black fly is frequently a most troublesome pest on young plants. Use the following wash:—A pound of soft soap and a quarter of a pound of tobacco placed in a gallon of boiling water, stirred until the soft soap dissolves, and then covered over and allowed to stand until cool, when it is to be strained, adding five gallons of soft water. In this the plants are to be immersed with their heads downwards. It is an excellent wash for young plants infested with this pest, thrips, or green fly, and drawing the suckers through the mixture prior to potting frees them of these pests. It must not be used for plants showing for bloom.

Snails and slugs make great havoc among the seedlings and offsets; the succulent leaves of the *Cineraria* they always like. Lay fresh Cabbage leaves near the plants at night, and on examining them in the morning on the under side of the leaves

some will be found. Search for the marauders at night with a lantern, or sprinkle a little dry soot around the insides of the frames, around the plants, and on the surface of the pots or pans.

MILDEW is too well known to Cineraria-growers. Dust the infected parts with sulphur vivum, and wash off in a few days.—G. ABBEY.

NEW PLANTS

AS SEEN AT MR. W. BULL'S, CHELSEA.

ABOUT two years ago I visited this now well-known establishment, and endeavoured to describe the large collection of novelties that were then to be found there; and now again "the cry is still, They come." From all parts of the world, and from all departments of the vegetable kingdom, if not "from the Cedar of Lebanon to the Hyssop that groweth on the wall," at any rate from the magnificent Palm to the tiny Lycopod, are contributions levied to satisfy the ever-increasing cry for new things. Wherever anything good is to be obtained Mr. Bull is sure to have arms long enough to reach it, and the result is seen in the constant change of novelties that his houses display.

Of those which I spoke of last year I am glad to find that a large number have established the reputation that was then predicted for them; and of those which I have now seen I am sure that many will be found as great favourites as their predecessors. Let not any one imagine that it is only the owner of some large establishment who need apply here, for while there are denizens of the stove and Orchid-house, the lovers of Ferns whether British or exotic will find something to gratify their taste; the "bedder-out" may see some of the very best strains of Geraniums in existence; the exhibitor will find Verbenas which will help his stands; and the lover of herbaceous plants may add to his stock of gems. The difficulty is really where to begin, and how to obtain a supply of adjectives which shall be adequate for the demand made on them. However, to the Palms must, I suppose, be accorded the first place, especially as the taste for their cultivation seems to be rising in England. Foremost amongst these was *Verschaffeltia splendida*, a beautiful feathery-looking Palm, with the stem completely covered with thickest and sharp spines. Equally good is the plant now popularly known as the Thief Palm, a name which I should think had better be dropped, its true name being *Phœnicophorum sechellarum*. Here I would also mention among Cycads *Zamia cycadifolia* from Port Natal. Here, too, is the true *Lantana rubra* or Bourbon Palm, the one ordinarily sold as such being *Comersonii* (?), very handsome; and *Cycas plumosa*, very feathery and beautiful.

Of the now very popular family of Maranta, a good example was *Maranta splendida*, from Para, which has been already exhibited and obtained a first-class certificate: it has light green foliage banded with darker green. Amongst Orchids was *Schistocasia Portei* from the Philippines. *Amorphophallus nobilis*, from Java, was a remarkable-looking plant, with stems 4½ inches in circumference. Of those plants remarkable for their variegated foliage the greatest gems were *Bertolonia margaritacea*, a name thoroughly well-deserved, for the leaves look as if dotted over with pearls; and *Eranthemum argyrenuron*, similar in its habit of growth to *Gynnostachyum Verschaffeltii*, but entirely different in colour, which is a very bright lively green, and the nerves of a beautiful silvery white. This has been obtained from the High Amazons, and the entire stock of it is in Mr. Bull's hands. *Peperomia argyrea* has a large ovate leaf beautifully marked with spiral bands, while *Dioscorea anactochilus* is now well known. Its large leaves, 8 inches in length by 4½ in diameter, are produced first quite green, but gradually change to a bright olive and gold, very similar to some of those little beauties from whence its specific name is derived. *Bignonia argyrea violascens* has been so frequently exhibited lately by Mr. Bull that it ought now to be well known. It may suffice to say that it fully maintains its character for its beautiful soft colouring; and a variety of *Tradescantia*, white and green, will form a nice contrast to zebraina, so well seen and so much used in baskets. There was also *Ananassa Porteana*, from the Philippines, variegated olive, green, and white.

To remarkable-foliaged plants there were also some fine additions, such as *Pandanus latissimus*, a rare plant, with the broadest foliage known in this family, and *Pandanus Porteans* from the Philippines. There was likewise from Madagascar a

very pretty plant, like *Pavetta borbonica*, but trifoliate. There was also to be seen *Cossignia borbonica*, not a new but a rare plant, with orange midribs and cinnamon-coloured stem, exceedingly handsome. Amongst curious-foliaged plants were some remarkable productions:—*Nidularia Pinellii*, with its inflorescence almost like a nest settled down in the heart of the plant, and *Coccoloba pubescens*, with a most curious character of foliage. The leaves are 32 inches by 28, slightly pubescent, and are produced apparently one above the other, giving, doubtless, to the plant naturally a most curious appearance; not more singular, however, than *Pitcairnia tabulariformis*, a plant about 16 inches across and as flat as a table, from the centre of which rises a spike of orange-coloured flowers. Amongst Orchids was a variegated-leaved variety of *Phajus grandifolius*, and *Vanilla phalenopsis*, very remarkable for its flowers.

In plants that come more within the reach of everybody Mr. Bull has a varied assortment of novelties, in Verbenas, Fuchsias, Pelargoniums, and Petunias. Many of these I have seen, and about their value there can be little doubt. His new Lobelias, for instance, open out quite a new field, and we cannot do better than quote the opinion of a contemporary, which says, "We hail these as great acquisitions; for the Lobelia is one of the good old summer flowers which have been elbowed out of the garden by the bedding system, though few subjects are more brilliant than it under good management." The colours of these new seedlings comprise many quite new, such as pink, carmine, and ruby; and we certainly see no reason why we should not have as great varieties in this flower as have rewarded the labour and skill of the hybridiser in other departments of floriculture. When the Italian Verbenas were introduced, poor as they doubtless were, I hailed their advent as being, I hoped, the precursors of a new race, and these anticipations have soon been realised. Mr. Bull has this season several, which I look upon as a great improvement on any that have been as yet sent out. They will not from their very character be of much service for the garden, but will be very pretty for pot culture and for the exhibition table, where their contrasts will be much valued. His double *Mimuli* are too well known now to need any comment. Their value is greatly increased by the lengthened duration of their blooms, the single *Mimulus* lasting only a very short time; whereas the calyx of these, equally ornamental as the flower, remains on for a long period.

I have more than once alluded to the superior strain of bedding Pelargoniums which Mr. Bull has possession of, some of those of last season being wonderfully fine in colour, and the individual flowers very large. He has this year again eight new varieties to send out, among which Edith, Cherub, Peach Blossom, and Speaker are spoken of as being very fine. Of Hybrid Nosegay varieties he has also a selection; and having chosen Clipper as one parent and Stella as the other, he has obtained for those who admire this class some telling novelties.

Fern-lovers are so numerous that acquisitions to this tribe are sure to be of interest, but where they are to stop one hardly knows. Thus, for example, from a crested form of *Nephrodium molle*, the spores of which Mr. Bull sowed in the hope of obtaining the same variety, he found that when once the divergence begins there is no knowing how far it may go; for a number of varieties have been produced, some of which have been named, as *ramosissimum*, *grandiceps*, *ramosum cristatum*. *Athyrium Filix-femina* contributes a very beautiful variety called *sagittatum*, with very sharp arrow-shaped fronds, somewhat in the style of *Fieldia*. *Polystichum angulare grandiceps* is a fine form of that well-known species; while amongst exotic Ferns, both tree and herbaceous, are many fine sorts.

It is well known that Mr. Bull has a large collection of officinal and medicinal plants. Here may be seen the various spices, such as Pepper, Allspice, Ginger, Cinnamon, and Clove; the fruits of the tropics, the delicious Mangosteen, the Loquat, the Mango, and the Date; the plants from which castor oil, ipecacuanha, sarsaparilla, and all such "nasties" are obtained; the plants or shrubs that produce our beverages, tea, coffee, chocolate, &c.; those in which ladies, and even men, like Hotspur's top, "perfumed like a milliner," delight as scents—that queer "opopanax," whose letters puzzled the town last winter, and patchouli, suggestive always of a dread of soap and water in those who use it,—in fact plants (many of them small, doubtless), whose interest is derived not from their extreme beauty but from the uses to which they are put.

Some people say you never can be tired of a good thing. Well, I honestly confess, great as is my love of flowers and

plants, I do become tired when, one after another, novelties are produced, and their beauties are to be recognised; and as I began this tour through Mr. Bull's houses at six o'clock in the morning, I can safely say I was ready for my breakfast when the time came. Many of the things which I have noted will be brought before the public ere long, and I shall not be surprised to find them much appreciated. All praise is due to those who, like Mr. Bull, Messrs. Veitch, and others, spare no expense in introducing new plants—doubtless with an eye to their own advantage, but I believe in many cases out of a sincere love for the objects of their care.—D., *Dial*.

THE PINE APPLE.

AND MR. THOMSON'S TREATISE ON ITS CULTIVATION.

If we look into the history of most of our fruits in the cultivation of which success depends more upon management than on natural advantages, we shall find that from time to time revolutionary changes have taken place in their treatment. The wisdom of some of these wide deviations from the beaten track was usually more or less questioned at the time, but when confirmed by success they soon became the general practice. The advent of Keens' Seedling amongst Strawberries was a great stride in the right direction, and that variety has retained its position up to the present day—not but that there are some even older varieties, as the Old Pine, Hautbois, and others still deserving a place; still none of the period to which I refer has enjoyed so long and well-sustained a reputation. Gooseberries, too, had their period of change, and the first quarter of the present century saw the weight of their berries advance from half an ounce or so to nearly four times that weight. This result, however, was effected more gradually than in the case of Keens' Seedling Strawberry, which might be regarded more as a lucky hit; for careful cultivation and selection from innumerable seedlings were the means by which the size of the Gooseberry was so much increased. Other fruits have likewise had their period of improvement—the golden age in their history. Now and then, it is true, there are misgivings about the wisdom of discarding some old favourites, still it is questionable whether the favourite Apples of 1806, even if produced in the condition they were in at that time, would not have to succumb to some of the later introductions.

Taking for granted the improvement effected in the Gooseberry and Strawberry during the last fifty years, the question is, Have other fruits advanced in an equal degree? With most of them some progress has doubtless been made, and especially in the management of the Pine Apple; but there is at least one other fruit which can hardly be said to have undergone any improvement during that period; on the contrary, we may ask ourselves the serious question if it has not retrograded, and the Peach certainly was grown to its great perfection thirty or forty years ago as now, and with much less trouble, whilst the crop was abundant. Why this should be so is a very grave question deserving of special inquiry; but as it is my object at present to direct attention to another fruit, I will proceed at once to that subject.

It is nearly two centuries since the Pine Apple was first introduced into our gardens. Doubtless its extension at that period would be very slow, for apart from the non-existence of those facilities of transit which now bring almost all parts of the United Kingdom within thirty hours' travel of each other, there was in early times a feeling of selfish pride in one person possessing what his neighbour did not. It is not necessary, however, to trace the early history of the Pine Apple; suffice it to say that the number of places where it was grown at the beginning of the present century was not great; but since then, the increase of wealth, and a more widely-diffused taste for horticulture, have tended to encourage the cultivation of plants and fruits out of the common way, and the Pine Apple amongst others received its share of attention. Each county could boast of a place where the Pine Apple was said to be well managed, and the young man who had the good fortune to serve his time at that place was considered to possess advantages over his fellows. By degrees, however, the culture of this fruit became extended, and the more general diffusion of garden literature enabled most people to comprehend that, after all, no secret was involved in the matter, and that no extraordinary management was necessary to attain a moderate degree of success; but that the whole affair was one of the pocket, coupled, of course, with some cultural details not difficult to understand. The expensive items being fuel and glass, re-

course was had to fermenting material as a substitute for the former, the space to be heated being at the same time limited as much as possible, and it was found that the plant rather liked this than otherwise. These modes of growing the fruit date much further back than my experience extends, but forty years ago some very good Pines were grown in England, and in a manner that is still pursued at many places at the present day.

So popular a fruit as the Pine Apple would not, of course, be cultivated in a few places without strange stories going forth as to the means used to secure success, and suspicions were entertained that beyond what was stated to the general public something of importance was withheld which the outer world were not to be made acquainted with. To help this delusion, marvellous results were now and then said to follow certain modes of treatment. Plants were said to have ripened fruit that individually weighed more when cut in the ordinary way with 3 inches of stalk than the whole of the rest of the plant, as well as the pot and soil in which it was grown. Some extraordinary results have doubtless been accomplished, but the dealers in the marvellous had their day, and horticultural exhibitions tended to dissipate false notions about these and other matters; for at such exhibitions it frequently happened that the produce of a place noted for a lifetime for its Pines was eclipsed by fruit grown by an exhibitor never before heard of. A good Pine Apple, however, continued to be regarded as the monarch of fruits, and was thought a fitting present to the highest in the land, and it is said that one of a family of note was knighted for some splendid fruit of this kind presented to the reigning prince at a particular time. The last thirty years, however, have witnessed the greatest advance in the culture of this fruit, and from being an object of curiosity rarely seen by the multitude, fruit imported from abroad are hawked about the streets, and sold at a halfpenny a-slice, and some of them are not to be despised for flavour and size. Before, however, such fruit had found its way into this country, some changes had come over the management of the Pine Apple in our own stoves, and resulted in its cultivation being more fully understood.

The impetus given to the erection of glass structures by the removal of the duty cannot fairly be said to have been of so much advantage to Pine cultivators as to those engaged in some other branches of gardening, and some of the great advances made in the cultivation of the Pine Apple took place before that period. Supplying bottom heat by means of hot water had been successfully carried out, and the steady heat afforded to the roots by that mode of communicating warmth led to the use of pots being altogether abandoned, the plants being merely planted in the bed which was heated from below, and great and manifold were said to be the advantages of this plan. By-and-by, however, it was found to have disadvantages, and recourse was had to pots again; but hot water was still used as the medium for supplying bottom heat. Some other innovations in Pine-growing were tried, and I believe a Providence Pine upwards of 13 lbs. in weight was grown without the use of fire heat in any way.

Soils, too, began to attract attention, and as is common in such matters, people went to great extremes. At one time some pinned their faith to charcoal, while another urged brick-dust as being as good as half-burnt wood, and great advantages were said to be derived from peat. This was strongly recommended in consequence of such extraordinary results attending its use in France, where it was stated fruit exceeding in weight any that had ever been grown in England were produced by the use of this material. The reign of peat, however, was not a long one, neither was it successful to any great extent, and growers had again to fall back on their own resources, and to adopt for themselves such substances as best suited their particular cases. In the latter view of the matter they were materially assisted by an excellent paper contributed by Mr. Barnes to one of the last numbers of London's "Gardener's Magazine," which was backed by some remarkable fruit obtained by the means he advocated. On the subject of soils, Mr. Barnes startled many who thought that mixtures of some half a dozen materials carefully and accurately compounded were absolutely necessary to anything like success, while the substance which he used for potting his plants was obtained from some moorland of very indifferently character. Mr. Barnes affirmed at the time, that land that would grow good Wheat would produce good Pine Apples; and certainly some very fine Queen Pines were sent by him to the metropolitan shows upwards of twenty years ago. This, as well as the other results above recorded, all happened prior to the cheapening of glass

structures by the removal of the duty. After the latter epoch, however, the number of Pine-houses and Pine-pits was much increased, and all the old and new modes of culture were in requisition, and fresh attempts were made in order to discover a more rapid and easy way of obtaining this fruit in perfection. Mr. Hamilton, in Lancashire, advocated the planting-out system, with closely confined pits, and a greater amount of heat than had hitherto been afforded. The planting-out system was also adopted at Trentham with good results. The number of places where Pines were grown increased rapidly, and certain districts appearing to have a decided partiality to particular varieties. In the neighbourhood of Manchester, where excellent Pines, and Grapes too, are grown, the Black Jamaica, or Montserrat, as it is there called, is the prevailing fruit. Queens certainly predominate near London, while our neighbours across the Tweed seem to give the preference to the Smooth-leaved Cayenne. The large Pines, as Providence, Charlotte Rothschild, and Envile, seem to gather in greater strength in the central and northern counties than elsewhere; but they are yearly giving way to the kinds before mentioned, and others of like quality at table, size having ceased to be regarded as a point of merit, unless other good properties accompany it.

The above outline of the cultural history of the Pine Apple, which the reader may, perhaps, complain of as being long and tedious, was intended as a preface to some notes which I purpose to make on a treatise on the cultivation of this fruit by Mr. David Thomson, of Archerfield, whom the readers of this Journal will remember as being one of the most able writers in its pages, and from whose pen occasional articles still appear. Of the merit of the work as a literary production I must leave abler critics to give an opinion, but as a work conveying a clear idea of the mode of culture adopted at Archerfield, and the results there attained, the testimony of an eye-witness may, perhaps, not be regarded intrusive by the author, nor mistaken by the public as being akin to puffing, for it will be perceived that something has, in my opinion, been omitted. Do not, however, let my saying this prevent the reader ordering the work at once, for I can affirm that it fully and faithfully reflects the practice of one of the best Pine-growers in the United Kingdom. More than this need not be said, and had I not seen the garden at Archerfield I would not have said this much. However, as generalities are useless without details, I propose in my next article to take the little work in hand, and commencing at the beginning, follow the author through such portions of it as may appear necessary.—J. ROBINSON.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

MAY 1ST.

FLORAL COMMITTEE.—Mr. Cox, gardener to W. Wells, Esq., Red-leaf, brought cut flowers of a seedling Camellia, a light rose colour; also, Rhododendron Aucklandii, and two kinds of Magnolia. Messrs. Veitch exhibited a new Lycaste with strong foliage and a large dull yellow and green flower; also, a collection of plants, consisting of Rhododendrons, Azaleas, &c., for which a special certificate was awarded. Mr. Turner, Slough, sent a very large and beautiful collection of Auriculas, affording good examples of this old favourite in its various forms of green, grey, and white-edged flowers; also many beautiful selfs or one-coloured flowers, and a beautiful collection of Alpines in every shade of colour. Never was such a group of Auriculas seen before; they were most deservedly the admiration of all who saw them, and well merited the Lindley medal which the Committee awarded them. Two of the seedling Alpines, Defiance, a dark-shaded violet flower; and Victorious, a bright-shaded chocolate with conspicuous yellow centre, received first-class certificates. Mr. James Hedges, Birmingham, sent cut flowers of Cattleya amethystina and Rhododendron lanifolium, a delicate rose-coloured flower. A very nice collection of stove plants was sent up from Chiswick, and a special certificate was awarded for them; also, a collection of Orchids from the stoves at South Kensington. A first-class certificate was awarded to Psychotria macrocephala, a beautiful plant exhibited by Mr. Bull at the previous meeting, some doubts being then expressed as to its having received an award.

FRUIT COMMITTEE.—Mr. Tillery, gardener to the Duke of Portland, Welbeck, sent Lady Downe's Grapes, damaged on the journey, but very good in flavour; and from W. Burrell, Esq., Ockenden House, Cockfield, came two kinds of Apples, the names of which were not determined. Richmond Late White Broccoli, a large-headed kind, was shown by Mr. Turner, of Slough.

FORTNIGHTLY MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. The awards having been reported, and nineteen new

Fellows elected, the Rev. M. J. Berkeley offered some remarks. The first subject touched upon was Psychotria macrocephala exhibited at the last meeting by Mr. Bull, and respecting which some doubts had been entertained as to whether it was really a new species of Psychotria or not; but Mr. Berkeley stated that he had been to Kew herbarium, and without venturing to say that he had compared it closely with some 170 species of Psychotria and twenty or thirty of Rudgea which he there found, he had great reason to believe it to be quite distinct. Rhododendron Princess Alice, from Messrs. Veitch & Sons, and another Rhododendron, unnamed, from Mr. Cox, of Red-leaf, were then adverted to, the former as a hybrid between R. ciliatum and Edgeworthii, and the latter as probably a form of R. cinnamomeum, Mr. Cox had also sent two forms of Magnolia consipiens, one cut from a tree covered with an extraordinary profusion of flowers, as well as an interesting collection showing the fructification of various Conifers. Rubus Girceoidiana, which was exhibited among the plants from the Society's garden, then came under notice, and it was stated to have been received from Berlin, but in the absence of flowers it was impossible to know whether it was a Rubus or not. It appeared, however, to be new. Two beautiful Gourds, both grown in the Botanic Garden at Hyeres, next occupied attention. That named Lageraria sphaerica came from Natal, and had been exhibited before; but the other, L. Monteiroi (Naudin), which was a native of the west coast of Africa had, Mr. Berkeley believed, never before been seen in this country. There was, in addition, a fungus sent by Mr. W. G. Smith, which was evidently a Morel, but apparently different from the ordinary one. Disease in Peach trees was the next subject to which attention was directed. This had been very prevalent, and on examining shoots which had been submitted to his inspection, he found that it had commenced in the terminal bud, and that the wood below it exhibited a number of little cavities. In the case of some trees in the Isle of Wight, the roots were found to be covered with little knots, and these were studded all over with facets from which adventitious roots would have been emitted under conditions favourable to their development. Those who had visited Chatsworth had no doubt admired an enormous Peach tree growing in a house at that place, and which was remarkable for the size and beauty of the fruit which it produced, but it, too, had fallen into bad health, as well as some other trees at the same place. The Duke of Devonshire applied to the Society to send some one to examine these trees, and Mr. R. Thompson went down to Chatsworth and made a valuable report on the condition of the trees. There was nothing apparently wrong in the management, but on examining the roots he thought that the bad condition of the trees must have been caused by some fungus. Shoots and roots were, therefore, submitted to Mr. Berkeley, and he found in every case, even when to all outward appearance sound, indications of incipient decay, and cells containing mycelium. The soil of which the border was made contained a large proportion of fibre and vegetable matter, such as was likely to favour the development of the spawn of fungi, and it was in a peculiarly solid and sodden condition. On mentioning the subject to Dr. Hogg he said that he recollected the trees being in the same condition some years ago, but on the soil being removed and the trees root-pruned, they again pushed vigorously. Some gardeners, Mr. Berkeley remarked in continuation, are in the habit of using forcing manures, but it is a dangerous practice, which, though it may cause increased production for one or two years, is often the cause of lasting injury; and he further recommended especial caution in employing those of which the composition is not known.

Mr. Saunders said that, before calling upon Mr. Bateman for his remarks on the Orchids, he wished to direct attention to a little Radish which by some extraordinary freak of nature had tied itself into a knot. This he ascribed to the tap-root having come in contact with some hard curved surface in the soil.

Mr. Bateman said, that before proceeding with his observations he had a grievance to complain of, which he hoped would be made public. On several occasions plants had been dispatched from the country to the Society's meetings, but had not arrived in time. Taught by experience, ample time had been allowed for the journey—as much was consistent with the plants arriving in good condition, but whether their delivery was left to the railway companies, or special messengers were sent after them to the terminus, the result had been the same; and, as an instance, it was not necessary to go further back than the last meeting, when Dendrobium MacCarthiae did not arrive, though dispatched in good time. He hoped, therefore, that something would be done to redress this great grievance. The first subject to which he would allude was a remarkable Pear tree growing in the vicarage gardens at Holme Lacy, the seat of Sir E. Scudamore Stanhope, Bart., and of which he had received a photograph. The tree formerly covered nearly an acre of ground, but much of it had been cut down from time to time, owing to its too closely surrounding the mansion. From fourteen to sixteen hogsheads of perry, or one hundred gallons each, had been made from its produce in some years. Mr. Bateman expressed a hope that the example of sending photographs of remarkable trees would be followed by others. With regard to the Orchids, the show was rather meagre, owing to the weather being so cold as to make those having valuable plants afraid to venture them from home. There were some, however, well deserving of notice, and among such was a fine specimen of Cattleya amethystina, which was only a variety, but a beautiful one, of the old C. intermedia; also, Lycaste Harrisonia, one of our oldest Orchids, of which a magnificent specimen

came from the Society's garden. The next subject to which he would refer was an Epidendrum of peculiar interest. Last year when lecturing on Dendrobium, he referred to a map showing the distribution of Orchids over the world, and he would again revert to it, in order to point out that in each continent a certain genus prevailed. Thus in Africa it was *Angraecum*; in Asia, *Dendrobium*; in America, *Epidendrum*. Between the last two genera no great difference existed as regards the number of their species. Last year there were somewhat more than two hundred species of *Dendrobium*, and about the same number of *Epidendrum*, and in the present year it would be difficult to say which genus had the lead. Although thus on an equality as regards numbers, there was a wide difference in point of beauty, for while a large proportion of the *Dendrobium* had found their way into cultivation, not more than half a dozen *Epidendrum* were considered worth growing. In the genus *Dendrobium*, ugliness was the exception, and beauty the rule; whilst with *Epidendrum* the case was just reversed. Of the latter, however, several fine species had yet to be introduced, and among such until lately was *E. erubescens*. A coloured plate of it which in no way exaggerated its beauty had been made by Miss Drake, for his work on the "Orchidaceae of Mexico and Guatemala," and this was exhibited to the meeting. The *Epidendrum* in question was thought to belong to the section of the genus having leafy stems, and collectors were, therefore, instructed to look for such a plant, but their researches proved fruitless, for the flowers are in reality produced from the pseudo-bulbs, a fact which was only discovered the other day by Mr. Skinner, at a sale at Stevens's. It happened that on that occasion several new species of *Epidendrum* were put up for sale, and accompanying one of these was a dried flower which Mr. Skinner recognised as being like that of *erubescens*. He accordingly purchased half a dozen plants for 21s., although had the fact been known that they were the long-sought-for *E. erubescens* they would have brought many pounds.

Mr. Skinner here observed, that another importation from the same collector was on its way to this country.

Mr. Bateman having remarked that cool treatment would probably be the most suitable for this *Epidendrum*, passed on to his special subject, *Dendrobium MacCarthiae*, of which a plant with a single flower was shown by his gardener, Mr. Sherratt. This beautiful species had been described about ten years ago in the "Botanical Magazine," where it was stated to grow pendant from the trunks of large trees in the forests about Ratanapora, and towards Galle, in Ceylon, where it was pretty generally known to the natives as the Rainy-month flower. Its purple and white flowers are produced to the number of four or five, in racemes 1 foot or 1½ foot long, during the rainy season, hence its native name. It might serve as an encouragement to plant collectors to state, that after all the island was thought to have been ransacked this beautiful species was discovered. Mr. Bateman then remarked that the annual rainfall in Ceylon averaged 120 inches, and four-fifths of that amount fell between November and May. It would, however, be interesting to know what was the climate of the particular district of the coast where the plant is found.

MAY SHOW.—The first principal Show for the season was held on the 3rd inst., and was well attended by exhibitors notwithstanding the cold and unfavourable character of the early part of the day, which no doubt served to deter many from risking their valuable Orchids and other tender plants from home. The afternoon, however, was tolerably fine, and there was a numerous and fashionable company to witness what was altogether a very gay display of flowering plants, prominent among which were Orchids, remarkably fine Azaleas and Roses, and for the season very good Pelargoniums.

STONE AND GREENHOUSE PLANTS.—Mr. Donald, gardener to J. G. Bardsley, Esq., Leyton, contributed an excellent collection, consisting of *Medinilla magnifica*, with fifteen fine spikes of bloom; a fine specimen of *Stephanotis floribunda*, which when more fully in bloom will be very beautiful; *Vinea oculata*; a fine plant of *Eriostemon linearifolium*; *Azalea purpurea*, and *Hedera tulipifera*. From Messrs. Lee, of Hammersmith, came a fine plant of the last-mentioned, measuring about 4 feet through in every direction, and with its numerous pendulous blooms very bright in colour; *Fraxinea confertiflora*; *Epacris grandiflora rubra*; a good plant of *Erica verticillata coccinea* minor; *Hibbertia Reddi*, and *Boucauvilla glabra* trained as a balloon-shaped specimen, and in that form having a very good appearance as an exhibition plant. In a miscellaneous collection from the same firm were *Adenandra fragrans*, not yet in perfection; the beautiful *Chorodendron Thomsonii*, *Chorozema*, *Hedera fuchsoides*, a *Stephanotis*, two or three *Heaths*, *Azaleas*, *Camellias*, and a white-flowered *Epacris* from New Zealand. Messrs. Cutlish also exhibited a collection of small plants, among which were a number of dwarf standard Azaleas in good bloom, *Heaths*, *Eriostemons*, *Bononias*, *Aphelaxis*, and *Chorozema*.

Awards—First, Mr. Donald. Second, Messrs. Lee.

Orchids constituted one of the principal features of the Show, but were not so numerous as would have been the case had the weather been finer. They made, nevertheless, a very good display. The only collection of twelve put up for competition in the Nursery class came from Messrs. Lee, and included *Phalenopsis amabilis* and *grandiflora*, *Cattleya Skinneri* and *amoethystina*, *Acrides roseum*, *Saccolabium guttatum* and *ampullaceum*, *Cypripedium barbatum* and its variety *superbum*, *Oncidium roseum*, and *Dendrobium nobile*.

Mr. Bull also exhibited a collection of twelve, in which were a *Phajus* with six spikes of bloom, *Cypripedium Hookeri* and *villosum*, and a *Lycaste* unnamed; but as the rules with regard to entries had not been complied with, it was excluded from competition. In the class for nine several good groups were shown. That from Mr. Penny, gardener to H. H. Gibbs, Esq., Regent's Park, consisted of two varieties of *Cattleya Skinneri*, *Cypripedium Lowii* and *villosum*, *Vanda nauiis*, *Phalenopsis grandiflora* with two remarkably fine spikes of bloom, *Oncidium sarcodeis*, very handsome; *Dendrobium albo-sanguineum*, and *Trichopilia crispata*. From Mr. Page, gardener to W. Leaf, Esq., came *Vanda tricolor* and *insignis*, *Phalenopsis*, *Cypripedium barbatum*, a *Lycaste*, supposed to be a variety of *Lawrenceana*, *Acrides virens*, *Dendrobium tortile roseum*, and *Oncidium amplexatum majus*, the last one of the most effective Orchids in the Show, having two fine spikes bearing numerous flowers. Mr. Hill, gardener to R. Hambury, Esq., The Poles, Ware, also contributed some fine specimens, especially two large *Vandas*, being *Kolliasson's* and *Veitch's* varieties of *Vanda nauiis*, some excellent *Dendrobiums* and *Cattleyas*, *Phajus grandifolius* with ten fine spikes, and *Chysis Limmingtonii* in fine condition. Mr. Robson, gardener to G. Cooper, Esq., Colbury Road, had also a well-grown example of *Phajus grandifolius* with nine spikes; *Phalenopsis Schilleriana* with a fine spike; *P. Ludde-manniana* bearing two blooms, the older *P. amabilis* and *grandiflora*; *Vanda tricolor*, *Trichopilia tortilis*, and *Cattleya Mossiae*. Mr. Howard, gardener to J. Brande, Esq., Balham, sent a collection of six, among which there were a fine specimen of *Cattleya intermedia*, *Dendrobium pulchellum*, forming a pretty mass of pinkish lilac and orange blossoms, and several others of the same extensive and ornamental genus. In the class for single specimens *Dendrobium Farmeri* with eight fine spikes, and *Lycaste Skinneri* with upwards of a score of blooms, the one from Mr. Howard, the other from Mr. Penny, received equal first prizes.

Awards—For twelve; second, Messrs. Lee. For nine; first, Mr. Penny; second, Mr. Page; third, Mr. Hill; extra, Mr. Robson. For six; first, Mr. Howard; second, Mr. Robson. For single specimens; Equal first, Mr. Penny and Mr. Howard.

AZALEAS.—Mr. Turner again produced magnificent pyramidal plants, ranging in height from 5 to 6 feet, some perhaps more. The varieties were Holfordii dazzling in colour, Gem, Louise Margottin, Perryana, Petuniflora, Coronata, Mary, Madame Mielles, and Empress Eugenie. Mr. Carson, gardener to W. R. G. Farmer, Esq., had also half a dozen fine specimens, consisting of Duke of Devonshire, Stanleyana, Optima, Lateritia, Sir Charles Napier, and Holfordii. Half a dozen good plants were shown by Mr. Penny, and a like number by Mr. Young, gardener to R. Bardsley Esq. Single specimens consisted of a fine plant of *Iveryana* from Mr. Turner, a very large example of *Rubra plena* in excellent bloom from Mr. Carson, and *Macrantha purpurea* from Mr. Young.

Awards—For nine; first, Mr. Turner. For six; first, Mr. Carson; second, Mr. Penny. For a single specimen; first, Mr. Turner; second, Mr. Carson; third, Mr. Young.

PELARGONIUMS.—There was a gay bank of these, although the majority of the plants did not exhibit that profusion of bloom which they may be expected soon to attain. Those from Mr. Turner were the furthest advanced, and constituted a very attractive exhibition of themselves. They consisted of Beacon, Rose Celestial, Fairest of the Fair, Patrouess, Candidate, Lady Canning, Lilacina, Celeste, and Empress Eugenie. Mr. Fraser, Len Bridge Road, had good plants of Lurline, Fairest of the Fair, Mer Polaire, Rose Celestial, Leviathan, Roseum, Fair Rosamond, Beadsman, and Candidate. Mr. Ward, gardener to F. G. Wilkins, Esq., Leytonstone, had Fairest of the Fair, Nestor, Sir Colin Campbell, The Bride, Braeclot, and Lilacina; and Mr. Wiggins likewise sent a collection of six. Single specimens consisted of *Desdemona* in fine bloom from Mr. Turner, *Empress Eugenie* from Mr. Fraser, and *Rose Celestial* from Mr. Ward.

Award—For nine; first, Mr. Turner; second, Mr. Fraser. For six; first, Mr. Ward; third, Mr. Wiggins. For single specimens; first, Mr. Turner; second, Mr. Fraser; third, Mr. Ward.

ROSES.—From Mr. William Paul came an excellent group, comprising *Victor Verdier*, *Souvenir d'un Ami*, *Paul Ferras*, *John Hopper*, *Anna Alexieff*, and others; also, a fine specimen plant of *President*; and other groups were exhibited by Mr. Turner, Mr. Wiggins, and Mr. Bardsley, gardener to Mrs. Wood, Twyford Abbey, Acton.

Awards—For nine; first, Mr. W. Paul. For six; first, withheld; second, Mr. Wiggins; third, Mr. Bardsley.

FERNS.—An excellent collection of exotic kind, was exhibited by Mr. Barnard, gardener to J. W. Taylor, Esq., Woodberry Down, in which were fine specimens of *Cyathea mollularis*, *Cooperi*, and *dealbata*; *Cibotium princeps*, *Dicksonia antarctica*, and *Gleichenia speculata*. In another collection exhibited by Mr. Bull, there were a very handsome example of *Marattia degans*, large specimens of *Dicksonia antarctica* and *Cyathea dealbata*, *Alsophila australis*, and *Platyceerium alceiforme*. Mr. Peerce, gardener to E. Wood, Esq., Acton, and Mr. Young also furnished groups. Of Hardy Ferns, the finest group was that from Messrs. Ivey, of Dorking, which included several rare and beautiful forms of *Athyrium Filix-foemina*, such as *plumosum*, *Fieldia*, and its variety *diffusum*, *Vernonia crispum*; *Pseudathyrium flexile*, and a *Wardian* case of *Trichomanes radicans*. From Mr. Bull came *A. F. F. thysanotum*, *Jervisii*, *Vernonia*, and *sagittatum*, the crested Royal Fern, *Lastræa Standishii*, *Woodwardia orientalis*, *Polystichum*

angular Hellebora, a fine mass of *Trichomanes speciosum*, and *Hymenophyllum tanbridgeense*.

Awards.—For six Exotic kinds: first, Mr. Barnard; second, Mr. Bull; third, Mr. Preece. For twelve Hardy kinds: first, Messrs. Ivory; second, Mr. Bull; third, Mr. Young.

MISCELLANEOUS subjects, as usual, were numerous. Three fine plants of *Adiantum cuneatum* were shown by Mr. Bartlett, and a group of *Cinerarias* in good bloom by Mr. Lavey, gardener to C. S. Mortimer, Esq., Morden Park. From Mr. Parker, Tooting, came eight plants of *Rhododendron Comtesse de Haddington*, bearing a number of its large bluish flowers; *Rhododendrons* of the hardier kinds were also shown by Messrs. Ivory, who received a third prize in the class provided for such. Mr. Bull contributed a collection consisting of *Rhododendron Dalboasianum*, *Palms*, *Dracenas*, new double-flowering *Mimulus*, *Prunella intermedia*, *Zonale Pelargoniums*; also one of new plants, noticed beneath. Of *Arniculas*, Mr. Turner again produced the fine collection exhibited before the Floral Committee on the previous Tuesday; also a plant of *Trillium grandiflorum*, covered with its large white flowers. Of *Nosegay Pelargoniums* a fine collection was exhibited by Mr. W. Paul, and among them *Salmon Nosegay* was noticeable for its large trusses and the size of the pips. *Calceolarias*, *Pansies*, and *Arniculas* were again shown by Mr. James, and a number of handsome and tastefully filled plant-cases by Messrs. Barr & Snodden. A Prickly Cayenne Pine Apple of 7 lbs. weight, was also exhibited by Mr. Page.

FLORAL SUB-COMMITTEE, May 3rd.—Mr. Bull sent a new plant, *Macheraium firmum*, which was requested to be sent again; *Brownia princeps*; *Abutilon vexillarium*; and *Rhododendron Bianca*, a very pretty plant, producing small compact trusses of pure white flowers. The whole plant seemed to be a miniature form of *Rhododendron*. Its history we did not learn. As a useful decorative plant it received a first-class certificate. *Azalea Reine des Roses*, *Azalea Grande Duchesse de Bade*, *Azalea President Humann*, *Azalea Madame Dominique Vervaene*, and *Azalea Mont Blanc*, also came from Mr. Bull, but were not considered equal to existing varieties. He also exhibited three seedling *Petunias*—*Granville*, a white-striped flower; *Feresco*, a white flower with broad purple band; and *Aurita*, a well-formed dark purple flower. Mr. Page, gardener to W. Leaf, Esq., exhibited a *Phalenopsis*, which was determined to be a good variety of *P. grandiflora*, but with darker yellow markings at the centre; it was a very fine variety. Mr. Turner sent a large specimen of the old well-known hardy plant *Trillium grandiflorum*, producing a mass of its conspicuous three-petalled flowers. A special certificate was awarded it. Mr. William Paul, Waltham Cross, sent a collection of his seedling *Pelargoniums*; but it was much too early in the season to judge of their merits. Two were selected for awards: *St. George*, the darkest scarlet yet raised, with globular trusses of flowers—first-class certificate; *Salmon Nosegay*, after the style of *Duchess*, but a brighter shade of colour—first-class certificate. *Rebecca*, a fine rose shaded with purple, flowers of good form and truss large—it will prove a first-class plant when seen later in the season; *Phoenix*, bright scarlet; *Peach Nosegay*, fine deep rose with large truss; *Cardinal*, dark orange scarlet; *Sir Joseph Paxton*, a very distinct bright scarlet *Nosegay*; *Zephyr*, pale pink *Nosegay*, and *Wood Nymph*. When these plants shall have been seen later in the season, and in a more favourable condition, they will all take their stand as first-class flowers.

WEEKLY SHOW, May 5th.—In the class for the best collection of three *Pelargoniums*, Mr. Beasley, gardener to Mrs. Wood, Twyford Abbey, Acton, received the first prize; and in that for six miscellaneous plants, Mr. Young, of Highgate, was first, and Mr. Beasley, second. For three *Azaleas*, Mr. Young was again first, as well as for the best collection of cat flowers, for which Mr. Bartlett was second. Mr. Morgan, gardener to the Marquis of Townshend, obtained a prize for a fine dish of Strawberries; and Mr. Beasley one for a fine dish of Black Hamburgh Grapes. In the miscellaneous class, Messrs. Catbush, of Highgate, received prizes for twelve *Hyacinths*, for twelve miscellaneous plants and *Azaleas*, and for six very fine pots of *Forget-me-not*. Mr. Bartlett exhibited three handsome specimens of *Adiantum cuneatum*, for which he received a prize; and Mr. Young was equally successful with a collection of Ferns. Messrs. Lucking received a first prize for a collection of *Pelargoniums*, and Mr. Morgan a first-class certificate for flowers of *Gloire de Dijon* Rose.

COCOA-NUT FIBRE REFUSE.

For thirteen years this refuse had been accumulating, and we thought it would ultimately become a trouble and expense to us. In 1862 we had just commenced burning it with coal tar under our steam-engine boiler in lieu of coal, when the late Mr. Donald Beaton drew our attention to its valuable uses for the garden, and induced us to advertise it. In the course of four years we have sold about three-fourths of these mountains of refuse, besides what we have been producing in the meantime, so that shortly we fear there will be very little to be had, for during the last few years the supply of Cocoa-nuts has been decreasing and the price increasing. We, of course, lament this, and so will all those who have used this refuse if we may

judge from their repetitions of orders for it, and their letters expressing the satisfactory results in the variety of uses to which it has been applied.—J. BARSHAM & Co.

THE MANGO AND MANGOSTEEN.

HAVING received several communications impugning the correctness of the statements made by our correspondent "J. H." relative to the cultivation and fruiting of these tropical trees, we thought it due to the public, to our correspondent, and to ourselves, to ask him to inform us where and when he had produced those fruits in England. Several letters have been interchanged between us; but on our asking permission to publish them, our correspondent declined giving that permission. He has sent us, however, the following, which is a fair summary of his various replies:—

"Dear Sir,—In answer to your letter of the 4th inst., requesting me to allow our correspondence to be published in THE JOURNAL OF HORTICULTURE, I beg to say that, as the letters were all written without the very faintest idea of their being made public, I must decline to accede to your request. At the same time, as I said before, you are perfectly at liberty to give my name and address to any one asking for it.

"With regard to the small Mangosteen tree alluded to by your correspondent in last week's Number, it was fruited by me at my father's residence at Allestree, near Derby, in the years 1859-60-61; but much of the fruit was not ripened, as my means for growing it consisted of only one small house at that time, and I have, since writing the article on the subject, made the discovery that it was not the true Mangosteen, but the sort commonly sold as such. I must, however, mention that all the Mango or Mangosteen trees I have sold during the last three years have been, with few exceptions, imported by myself from Karang, or Singapore, where our gardener at the time I speak of is now living; and I say to you, as I said to those ordering plants, that I am always ready and willing to take back any Mango or Mangosteen trees if in as good a state as when I sent them out.

"I have for some years, as I mentioned to you when I sent my first papers to your Journal, given up growing tropical fruit trees for fruiting-purposes, as I have not the means now for so doing; but whether my instructions are contrary to the condition under which the tree usually grows or not, I will guarantee to take any moderately sized Mango or Mangosteen tree now, and before this time next year, by my mode of culture as detailed in your pages, have it in blossom if not in young fruit, provided any one interested in the experiment will pay the necessary expenses should I succeed.

"I must add, in conclusion, that I am truly sorry I was ever persuaded by friends who have had trees from me to send the papers on tropical fruit culture to your Journal, and I am still more grieved that my statements should have been taken to mean more than I intended when writing them; but I can truly say that my one only object was the earnest wish to see these noble tropical fruits more generally cultivated.—J. H."

We do not coincide with our correspondent in regretting the publication of his communications, accepting them as truthful. They have aroused attention to the subject; and but for such arousing he would have gone on inculcating that about the Mangosteen which he now finds was based on error.

More than one inquiry has reached us relative to another "tree," which our correspondent has been offering for sale under the name of *Passiflora macrocarpa splendens*, stating that it bears an excellent fruit weighing from 10 to 14 lbs. We can only say that it is not mentioned in any botanical work that we know, nor do we know any *Passiflora* that assumes the habit of a tree. There may be some mistake here also.

HORTICULTURAL DINNER.—We are glad to hear that a large number of gentlemen holding leading positions in the horticultural world, have given in their names as stewards of the dinner. The meeting at St. Martin's Hall on the 24th promises to be one unparalleled in character in this country, and the seats are rapidly filling up; gentlemen intending to dine should make early application for tickets, or they may be too late. A better chairman than Lord Henry Lennox could not be obtained—at once genial, sympathetic, and a graceful and fluent speaker. The dinner will be provided by Messrs. Spiers and Pond, and it being the first public dinner they have attempted in London on a large scale, there is no doubt their

extensive resources will furnish *material* worthy of the occasion. We are desirous to announce that through an error of the engraver the tickets have been printed Tuesday, May 21th, instead of Thursday, May 24th.

CULTURE OF VINES IN POTS.

(Continued from page 303.)

Am.—Until the Vines break the house may be kept closed, for then a much more humid atmosphere can be maintained; but should ventilation be necessary to keep down the temperature, air must be given, advantage being taken of sun heat to close early, for such heat is vastly superior to that which is artificially supplied. After the eyes have broken air must be given, but, from the dullness of the winter months, if we wait for the sun before giving it the shoots may become as weak as straws. A little air should be given daily if possible, if only for an hour or two, so as to afford a change of atmosphere. When practicable, affording a little air constantly is the best way to avoid lank growths and thin leaves, neither of which give fruit worth the pains. It is galling to devote a house to Vines in pots for early fruit, and find the leaves scorched by the sun, or flagging after dull periods, and the bunches twisting or curling into tendrils, as is commonly the case. I am certain that the principal evils attending the early forcing of Vines are to be traced to a deficiency of air in the early stages of growth. Until the leaves attain their full size air is particularly essential, in order that the parts that are to feed the crop may be capable of performing their functions. A little air, then, on dull days does good, and it should be given more abundantly with the increase of temperature. On dull days, when the temperature by day may be only 5° higher than by night, a little air may be given for an hour or two, which will be sufficient to cause a change of atmosphere. On cloudy days with clear intervals air should be given when the thermometer has risen 10 above the night temperature, and on clear days when it registers 10° higher than in the night, increasing the amount if the temperature rise more than 5° after the first admission of air. Ventilation should never be resorted to to lower the temperature; but the latter, whatever it be, should increase after ventilation is given, or at least be maintained. If ventilation lower the temperature either the house is too warm or air has not been admitted sufficiently early. When the temperature declines, then is the time to shut up the house, and not to admit much air.

Provision being made for the admission of a little air at all times, the house being heated sufficiently to admit of this, air should be afforded when the thermometer reads 10 higher than the night temperature, which I will for the purpose of illustration suppose to be 60°. Air will then be given at 70°, not in such quantity as to lower the temperature, but so that the latter may increase. The temperature increasing 5° more, if the sun's power is likely to raise it still higher the maximum amount of air may be given, but so that the mercury may rise ever afterwards. It may rise to 80° or 85° and will do good. The amount of air should be reduced when the thermometer first begins to fall, and, beyond the little left on day and night, no ventilation should be afforded by the time the heat has fallen to between the maximum day temperature (75°), and the highest extreme (80° or 85°); but in any case the house should be shut up by the time the temperature has fallen to 75°. On cloudy days with clear intervals it will be impossible to adhere rigidly to this rule without continually opening and shutting up of the house, but it will be found that any trouble taken on such days has not been misspent.

When the Grapes change colour more air may be admitted; and if not hitherto given at night and in dull days it should now be afforded, otherwise moisture may condense or be deposited on the berries, and it is destructive to the bloom. At this period air must be given early, or before the atmosphere has become heated to any considerable extent; for the heated air will deposit moisture on the berries, because they will not become heated so rapidly as the surrounding atmosphere, and so long as they remain colder moisture will be condensed on them; hence the necessity of increased ventilation when they are colouring, so that the atmosphere may not be rapidly heated, or become much warmer than the berries. This is an important point, for an indifferently or spotted bloom on the berries is frequently to be attributed to allowing the moisture to condense on them after they change colour, and not to syringing up to the time of colouring, as is often asserted. Providing

air be given early (and it is of no use giving it late), no harm results to Grapes from a judicious use of the syringe. I say, Use it, employing clear rain water only, and heated to the temperature of the house. It is want of air early that causes the leaves to scorch, or allowing moisture to condense upon them whilst the sun is causing rapid evaporation. The foliage of trees under natural conditions is not scorched after a shower, but under glass the leaves suffer from this evil, because we do not give air to carry off the moisture. The berries very often spot from the same cause. Bad glass is also a frequent cause of the leaves being scorched. Syringing has nothing to do with it. It does not matter whether the leaves are wet or dry when the sun's rays fall upon them, if only there be air to keep the atmosphere from being more suddenly heated than the water on the leaves, and to carry off the moisture evaporated instead of allowing it to condense. If the moisture is not carried off by giving air early, it will condense upon the leaves, and they will scorch without being syringed.

Fresh air cannot be admitted too early, but it may be in too great a quantity, and so cold as to lower the temperature, and thus stagnate the growth. Various schemes have been adopted to effect the heating of the air before it comes in contact with the Vines. I find nothing answers so well as a piece of tiffany nailed over the ventilating openings. It breaks the current of air if it is disposed to rush into the house, and the heated and vitiated air is driven out at the upper part of the house. It is of no use admitting air in front if the vitiated air is not allowed to escape at the back. We want to displace foul air by fresh. It is hardly necessary to admit air in front in the early forcing of Grapes; but if it is given there the openings should be on a level with the hot-water pipes or flues, or, better, when a little below them, and so contrived that the cold air entering passes over or comes in contact with the heated surface, and thus becomes warmed before it reaches the Vines. To prevent currents, a piece of tiffany or hexagon netting doubled should be fastened over the external openings.

—G. ABBEY.

(To be continued.)

NEW BOOK.

THE FRUIT MANUAL.

The Fruit Manual: containing the Descriptions, Synonymes, and Classification of the Fruits and Fruit Trees of Great Britain, with Selected Lists of the best Varieties. By ROBERT HOGG, LL.D., F.L.S., Pomological Director of the Royal Horticultural Society of London; Author of "British Pomology," "The Vegetable Kingdom and its Products;" and Co-Editor of "The Journal of Horticulture." Third Edition. London: Journal of Horticulture Office.

THIS, the third edition, is really a new book, and contains many varieties and kinds of fruits not described in the previous editions. These fill many more than one hundred additional pages; but we cannot do better than quote a passage from the Preface:—

"In the present edition the main features are,—a great increase in the number of varieties described; an entire revision of the synonymes, in which some errors in the previous edition have been corrected; new classifications of the various Fruits, with the exception of the Apple and the Pear, which I have not yet succeeded in arranging to my satisfaction; and greatly enlarged and re-constructed lists of the most select varieties of the different kinds of Fruits, serving as a guide to those who have no other means of knowing what are and what are not worthy of cultivation."

CHERRIES AT CANTERBURY, NEW ZEALAND.

THAT the Cherry is equal to the Peach in the shape of stone fruits in this part of the world, there is abundant proof this season in my fruit garden, for the greater part of my trees are heavily laden with abundance of fruit, and of the finest quality.

The first I will mention is Bigarreau Napoleon; for size the fruit are more like Plums than Cherries. It is a French Cherry. It is also a good bearer, resembling the old Bigarreau, but darker-coloured, and of first quality and first size.

The second is the May Duke, not so large as the first, but possessing many other good qualities.

The third is called Black Tartarian, generally considered to have been brought into England from Russia. It is also stated to have originated in Spain, whence it was transmitted to the Russian gardens, and through them into England. At any rate, let its history be what it may, it is a Cherry of great ex-

cellence. It is also, like the May Duke, valuable for its earliness, and is a good bearer in this country.

I have picked 336 lbs., or 3 cwt., of ripe early Cherries from December 11th to January 5th, 1866, inclusive, and exclusive of the Morello, Kentish, and other late sorts, which are now (January 8th), ripening. They have realised me 1s. per lb. from first to last, and were grown on very young trees.—W. S., *Acroside Botanic Garden*.

NOTES ON THE WAY TO THE HOLY SEPULCHRE.—No. I.

If we take the map of the world, and cast our eyes on the Mediterranean Sea, how insignificant it appears; save for the narrow inlet of the Straits of Gibraltar it might be taken for an inland lake; and yet when England was inhabited by "barbarians," and America was even more problematical than the North-west Passage, the blue waves of the Mediterranean bore on their bosom the wealth and civilisation of the entire known world. Yea, and more than this—how much more many a Christian can tell.

In those days of the "long ago," when the Roman empire extended far away beyond the countries washed by the waves of the "Great Sea," a poor prisoner was being sent in "a ship of Alexandria" to answer for conscience sake at Rome—Rome the central point of civilisation and of idolatry. Strong in the power of a faith that made even bonds and afflictions unworthy of comparison, the prisoner stood amidst his fellow passengers always ready with words of encouragement and of needful help. He was no common man; learned, even amongst the most learned, he possessed an intelligence so keen and subtle, that at times his great power of reasoning led those who listened to him without the power of following his argument, to accuse him of madness, and yet so humble withal, that he counted all his acquirements as less than nothing, so only he might be clothed with a stronger faith and a deeper love in Him for whose sake he was a prisoner. He had gone through much—loss of friends, loss of power, loss of wealth; he was on his way to bonds and death: but these things had no power to move the deep tranquillity of a soul at rest; and as he stood on the deck of the rude vessel making its slow progress against a contrary wind, he watched the sun sinking, as it were, beneath the waves, and as its last edge dipped below the horizon, he saw it emit that instantaneous dazzling light of emerald green that is never seen save in stormy weather, and then only for a moment. Did the sun setting in the troubled waters speak to him, as it speaks to us, of light unquenchable?—hidden sometimes from our sight, but never less dim than when our straining eyes watch its momentary eclipse.

We cannot enter into the deep loneliness of that poor prisoner. Surrounded by men who did not recognise in him other than a common malefactor, they neither believed his word or listened to his voice. They knew not what they did, nor what great message their ship was bearing through the sea; the very elements themselves ministering to its publication and success. At Sidon, at Myra, and then in the Alexandrian vessel passing onwards to Crete, the good tidings were heard—tidings which fell like good seed on a fruitful soil, and have brought forth the most glorious harvest this earth ever witnessed.

We can follow the weather-beaten vessel on its perilous way till it comes to its rocky anchorage within the protection of the "Fair Havens." Through the able researches of others*, we can almost see the very spot where the vessel anchored; the graceful sweep of the waters, as in their tideless beauty they wash the sandy, rock-surrounded beach. The bold rocky islets advancing into the sea, forming the main shelter of the Havens. We can also notice how the Havens, by being exposed to the east and south-east winds, would be unsafe, and "not commodious to winter in;" and what is even more to the purpose, we can land on the island and wander about amidst the records of the past, amongst the most interesting of which, perhaps, will be the ruins of the little chapel on "the dark slaty ridge rising immediately over the western bay," and still dedicated to St. Paul, most probably marking the very spot where the Apostle himself used to preach to the natives of Crete in their "own tongue, the wonderful works of God."

From this spot we can pass on over mountains bright with *Ranunculus*, the *Fritillaria tulipifolia* "white as a Snowdrop,"

and as delicate as a wax plant," and the *Salvia cretica*, "a fine and beautiful shrub," bearing purple blossoms—or through valleys abounding in Vines and Dates, in Oranges, Lemons, and Pomegranates. We may rest beneath the dark evergreen shade of the *Ceratonia siliqua* or Carob tree, or listen to the nightingale of our native woods pouring forth floods of harmony from groves of Olives; we may pass through villages inhabited only by lepers, where the watercourses are shaded by Oleanders, giving forth their gracious beauty to the poor leper's gaze as freely as when they dipped their trembling buds in the lake of Galilee, as the shadow of the Saviour passed by; we may stay to look at an evergreen Plane tree, the existence of which was mentioned by Pliny; or we may examine Roman remains, or those of classic Greece, all speaking of ancient prosperity, and of grandeur passed away.

Thus wandering on, still hearing in our minds the memory of the ruined chapel over the western bay, and of the prisoner brought by the ship of Alexandria, preaching glad tidings to listening Cretan crowds, let us enter the village of Khadra on a summer's afternoon in the year 1851, and we shall find that the echoes of the good news are still ringing through the island.

"As I entered Khadra," writes Captain Spratt, "there was a bustling activity going on with every male inhabitant present, twenty or thirty of whom were carrying stones to a particular building, whose walls were just rising a few feet above the ground. It was the rebuilding of one of the village churches. Old and young, priest and layman, were for the moment all builders and masons under the guidance of a hired master, and were carrying large stones from some distant ruin, or bringing the mortar to cement them in their appropriate places. It was an interesting sight; for this half-hour's earnest individual labour at the close of the day was thus devoted to religion. Some were evidently past labouring for their own subsistence, yet they too carried their load, although with distress under the mere pebble they could bring; yet it was carried by some of threescore and ten or more, and was thrown into the general heap, as the widow cast her mite into the common receptacle."

So the gift of the Cretan tongue at Pentecost was no idle gift, and the detention of the "Prisoner of the Lord" at the Fair Havens no accident, but rather the interposition of Providence for the salvation of souls.

How bountiful Nature has been to many a favoured spot in this beautiful island is proved by ancient as well as modern writers. It has been called the "garden of the whole universe," "the goodliest plot," "the diamond sparke, and the honney spot of all Candy." One district—Melavisi, is famed for its wine; another—Sfakian, is celebrated for its fresh cheese, called "Sfakian masethra," which is described as being as delicious as that of the island Samothraki; another produces Wheat from which is made the most delicious bread. We read of Chestnut groves, of wild Vines, like gigantic creepers, entwining tall trees of Plane, and Elm, and Oak up to their very tops; the pendent tendrils, together with leaves and bright red Grapes hanging from their branches in graceful festoons; while Myrtle and Yellow Broom, and numberless bulbous plants, form a carpet at their feet.

And it was from this goodly land that the Alexandrian vessel, contrary to the advice of the Prisoner on board, turned away to continue her voyage, as was hoped, to Phœnicæ, another haven of Crete. When the south wind blew softly, they thought they had chosen wisely and well, and how foolish they should have shown themselves had they "hearkened" to the prisoner and remained in the less commodious haven; but the course of the Alexandrian vessel was guided by a Master whom even the "winds and sea obey"—she carried merchandise to which gold and silver are as dross. Rising up from the waters of the Great Sea there was yet one other island destined to hear and to lend a willing ear to the good news the prisoner had to tell. Ere long a violent storm arose against the doomed ship. For fourteen days the fasting shipmen strove against the tempest till all hope seemed gone, and then the Prisoner stood forth amongst his fellow men in his true character as the messenger of God, and in their hour of terror, and, as they feared, of approaching death, they recognised his mission and obeyed his voice.

We can all picture to ourselves the shipwreck that followed the storm—the low white coast of the island of Melita—the "barbarous" yet kindly-hearted people burying down to the beach with words of welcome to the poor mariners. We can, as it were, see them lighting the unwonted fire, "because of the

* "Travels and Researches in Crete," by Capt. T. A. B. Spratt, R.N.

present cold"—the serpent coming out of the fire and fastening on the prisoner's hand; the barbarous people, ready then, as we are now, to mete retribution and judgment to others according to our own ideas of right, eagerly watching for what should follow. We can note the change from suspicion to veneration, as in Arabia the prisoner's persuasive voice addressed the wonder-stricken people, for this picture has been familiar to us all from childhood, St. Paul's shipwreck and his residence at Malta being one of those striking recitals that lay hold on the mind with enduring tenacity; and we do not wonder as we read of the attachment of the descendants of these very barbarous people to their faith, and of the sacrifices they are ready to make for the maintenance of their churches, which in even some of the villages surpass in splendour many a cathedral in Italy.

For three months St. Paul remained on the island. We cannot help longing for a more minute record of his visit than that bequeathed to us, so that we might follow his steps as he went about on his errands of healing and mercy, and see as he saw the face of Nature as it rose from its wintry sleep.

By looking at Malta as it is now, noting its produce, its trees, and flowers, we shall find some features that remain unchanged; we shall in some sort see as with St. Paul's vision, and know a little of what those "things" were with which the grateful, kindly natives loaded the apostle when he departed from their island on his onward journey to Rome.

The great difficulty that the agriculturist has to contend with in Malta is its want of soil. Naturally the country is rocky and sterile, excepting in the valleys, where the earth is good and productive; but where Nature has been less bounteous, there the skill and industry of man have compensated for her shortcomings. Terraces are cut out in the rock, the earth carefully collected and placed—sometimes in depth not exceeding 18 inches—on layers of broken-up rock, and on these terraces plentiful crops of corn and cotton are grown, the want of rain in summer being supplied by heavy night dews.

The gardens of the flat-roofed houses are protected by hedges of Cactus or Prickly Pear, the fruit of which is eaten profusely by the natives. The chief sweetmeat of Malta, Caramilla, is made, or rather flavoured, from the expressed juice of the pod of the Carob or Locust tree, while the pods themselves, which are produced in clusters from the knotted parts of the tree, are useful as fodder for the horses and cattle. The *Hedysarum coronarium*, with its large clusters of crimson blossoms, is used largely for fodder, as also is green Barley. Oats are not grown, nor is there meadow land to any extent. There are a few Olive trees, but no Vines. Pomegranates are to be met with, and considerable quantities of small Figs, the latter being always eaten on St. John's day, and called St. John's Figs.

Malta has been celebrated from very early times for its manufacture of fine linen cloth, which was much prized by the Romans even in their most luxurious days. An English loom has lately been introduced, and shows to great advantage by the side of those of native manufacture, which at best are but rude performances.

The natives of Malta—the true descendants of the barbarous kindly people of St. Paul's day—are a fine, dark, athletic race. The head-dress of both men and women is peculiarly picturesque, the former wearing a long conical-shaped cap of bright blue, falling over the head and hanging down at the side, while the women add to a dark dress the Spanish-looking black fal-detta. Their language is, as it has been since Malta had a history, almost pure Arabic.

The most common wild flower is the Borago; but there are many others that rise up by the wayside and divert the attention from the too great glare of the white roads and rocky terraces; amongst these the *Mathiola tricuspidata* is, perhaps, the most lovely; it bears flowers of a bright lilac hue amidst a cluster of silvery-looking leaves, and even in death it has a sweet scent like a Primrose. The *Gladiolus segetum* or *communis* rises up as in Italy amidst the green corn, while on the hillside facing the glorious sea that breaks triumphantly against giant reefs of rocks you may gather the little yellow *Aeonis aestivalis*, the Tenerian *fruticans*, *Ophrys fusca*, and *Bellevalia comosa* (called by some botanists *Muscari comosum*). Besides these there are the *Nigella hispanica*, *Lavatera trimestris*, *Psoralea bituminosa*, *Tetragonolobus purpureus*, the *Chrysanthemum coronarium*, and many others of which I have no account.

I have never seen any Fern from Malta, and the absence of streams, springs, or indeed of any save artificial watercourses, would make the country uncongenial to them.

The flowers I have mentioned are the flowers of spring, such as would have cheered the shipwrecked Apostle as he went about following the footsteps of his beloved Master in doing good, the "Shallow of the Great Rock in a weary land." The fertilising dew, the Lilies of the field, the sea, the ships, may all have furnished the illustration for that preaching which confirmed the faith of Christ so powerfully in the minds and hearts of the Maltese people, that no bribes or threats have ever once had the power to make them, as a people, swerve or change.—*FELIX-FEMINA.*

CUCUMBER CULTURE AND HOUSE.

I HAVE read with interest the articles on Cucumber and Melon culture which have appeared in THE JOURNAL OF HORTICULTURE, and agree with Mr. J. Wills in every respect but one. He recommends the sowing of five or six seeds in a 60-sized pot, and the plants to be separated as soon as they are up. Now I do not like this practice; there is far too much danger attending it. The way in which I manage my plants (and I never have a mishap, although I raise scores every year), is as follows:—

I take a 40-sized pot, and put about 2 inches of good fibrous soil over the drainage, leaving the pot about half full; I now put in the seed, and place the pot in a good bottom heat, about 80°. In about two days the seedlings show through the soil, and, when the seed leaves open, I put a little more soil round, and continue adding more so long as the plant grows, keeping only the seed leaves above the soil. This, I find, encourages root-action all up the stem, and very soon you have a fine strong plant and a pot full of good roots. As soon as the second rough leaf is open, I plant in the bed prepared for fruiting.

I enclose the design of my Melon and Cucumber-house. The dimensions are as follows:—Width of house, 11 feet; width of bed, 4 feet; depth of soil without the mound, 6 inches; depth of brickbat drainage, 18 inches; distance of soil from the glass in front, 18 inches; highest point in roof from ground, 10 feet 6 inches.

a Hot-air chamber.
b Brick drainage.

c Soil for roots.

o Ventilators.

d d Pipes for allowing hot air to escape from the chamber.

x x Hot-water pipes.

z Sliding door to chamber.

For ventilating the hot-air chamber I have two pipes above the pipe without the evaporating-pan, and three on the one with the evaporating-pan. I have also two sliding doors in the bottom of the chamber, so that I can have any heat I like under the roots, and either moist or dry.—*CUCUMIS.*

CHEILANTHES ODORA CULTURE.

ABOUT six weeks since I received a small box of plants of this most interesting little Fern, direct from Mentone. These plants were found within a walk of the town, and were well

grown and very healthy. Having experienced considerable difficulty in cultivating *Cheilanthes* on a former occasion, I determined to try a plan of my own, which had answered with another very tender Fern. I took a large pot, filling it for about 2 inches with drainage; in this I placed a smaller pot, with about an inch of drainage, filling up both pots with peat earth, mixed with a very little silver sand and a small, very small, proportion of cocoa-nut refuse. I planted the Fern, placing a glass over it, the glass removed from the soil about half an inch by broken bits of rock, so that air is admitted at all times. I keep the Fern in the window of the drawing-room, watering it every two or three days, taking off the glass while the moisture evaporates from the fronds. Some ten or a dozen new fronds have sprung up, and the whole plant looks as fresh and healthy as possible.

In the same window I have four pots of the *Cyclamen europæum*, which I brought last year from Florence, and which have been in bloom several weeks. Both leaves and flowers are considerably larger than they were when growing wild in Italy.

Some *Isias* (*crocata*), that I brought from Bologna are in full bloom; but the size of the flower is much smaller and the colouring far less brilliant than when I saw them in their royal home at the Villa Reale.—*FILIX-FEMINA*.

WINTER LINGERING IN THE LAP OF MAY.

THE past week has been one of the most severe I ever remember in the north of Ireland; Pears, Plums, and Apples, both late and early, are totally destroyed, although mostly covered with spruce branches and hexagon netting, which appear to have been useless. Young growths of forest trees, young Broccoli, Savoys, Cabbages, and all young seedlings are very much injured. The following are the correct temperatures taken by one of Cassella's registering thermometers—viz., April 29th, 9°; 30th, 4°; May 1st, 11°; 2nd, 4°; 3rd, 8°.—*E. WELCH, Palace Gardens, Armagh.*

THERE was a fall of snow at Teignmouth on the 3rd instant. At Chiswick, on that date, the thermometer fell to 26°, and in the succeeding night to 25°, or 7° below the freezing point.

FROST AND PROTECTING MATERIALS.

I WISH it were in my power to say with Mr. Bréchant, "that the winter is now happily past." We, who live amongst the hills of Yorkshire, have been enduring for the last ten days a most cutting wintry blast from the north-east. The distant hills are still white with snow, and the frosts at night are most severe. I shall never forget the destruction which the frost of the night of the 29th and morning of the 30th of April worked in my garden. The blossom on all the unprotected Plum trees was completely destroyed, even the more forward buds of the Morello Cherry were also killed. I do not, however, desire to relate the injury my garden has sustained, but rather to make known for the benefit of others the lesson which these frosts have taught me. Three different kinds of protecting material are used here to cover the fruit trees trained to the walls. Frigi domo, the improved make, 3 yards wide, at 2s. 8d. per yard, is used to cover Plums and Cherries and several Pear trees. This material was in excellent condition, had not a single hole in it, and was fastened against a south brick wall under a stone coping, which projected about 6 inches. The frigi domo hung down to the ground, and was prevented from pressing too close to the bloom by poles reared up against the wall, and yet, notwithstanding this careful protection, a most abundant crop of Plums has been almost entirely destroyed, and the blossom of the Pears has shared the same fate. About two-thirds of the bloom of the May Duke Cherry have also been cut off. Fifteen Pear trees on another south wall, and which were in full flower, were protected with stout harden. These trees have suffered but little injury. The blossoms of *Easter Beurré* and *Fondante d'Automne*, a delicious Pear, have been injured to some extent, but the other trees have sustained no damage worthy of mention.

Apricots, Peaches, and a few choice Pears were protected with a woollen material, a pattern of which I enclose for your inspection. Under this covering all the fruit trees were preserved from injury, even the tender bloom of the *Marie Louise* Pear has not a single mark of frost upon it. This is the eighth spring that this material has been in use, and it has never yet failed to resist the utmost severity of spring froths. It was purchased on the 6th of January, 1858, of Mr. Ashworth,

woollen manufacturer, of Haslingden, near Manchester. It is 1½ yard in width, and cost 1s. 7d. per yard. It is still in excellent condition, as the enclosed pattern will show, and will in all probability continue to be serviceable for several years to come. I hope I am not out of order in mentioning the name of the maker, for when I applied about two years ago to Messrs. Ashworth for a further supply, I was informed that they had ceased to make it; still, it is possible, in the event of a good demand for this material springing up, the firm might be induced to resume the manufacture of this invaluable protecting material.

The frost, then, has taught me—First, That frigi domo is a most inefficient protecting material; moreover, its cost is considerable, and it does not wear well. Secondly, That stout harden will exclude frost far more successfully than the frigi. It is also cheaper, as it can be bought 6 feet in width for 1s. 5d. per yard. It will last much longer than frigi domo, and can be easily procured of different widths to suit the height of wall. Thirdly, That the Haslingden woollen druggot is far superior to either frigi domo or harden as a protecting material, and if its efficiency and durability be taken into consideration, it would still be cheap at a higher price than 1s. 7d. per yard. If, however, this sort of druggot cannot now be obtained, an efficient material for protecting fruit trees from frost is still a desideratum.—*C. M., Cargrave Vicarage, May 1st.*

WEATHER WISDOM.

(Continued from page 201.)

IT has been previously remarked that in calculating the probabilities of future weather, the observer must never neglect to make use of a thermometer, and to note the readings of that instrument as well as those of the barometer. Such observations are always necessary, and of the greatest importance, because a rising barometer with a falling thermometer shows quite a different prospect of probable weather to that which a rising barometer and a high thermometer would lead observers to expect; not, however, when a barometer and thermometer are placed in a hall and hung up where both are influenced, more or less, by the rays of the sun, or by the heat of a fire. Then an attached thermometer is not of much use for weather wisdom, and only informs the observer of the temperature of the air surrounding the column of mercury, and for closer observations gives him the means of finding out how many hundredths ought to be deducted from the observed height of the column, the mercury in the barometer being affected by temperature. Such temperature must be taken into account in order to obtain a true reading in all critical observations.

While on the subject of thermometers, I think it may be of service to point out some of the chief causes which bring about such discrepancies in the readings of these instruments. I do not by discrepancies mean difference in temperature as compared with the temperature of the previous day, but discrepancies in the temperatures of places close to each other. Many of your readers, doubtless, remember the time when the readings of their registering thermometers differed considerably from those of their neighbours close by. All were good instruments, by good makers, and yet the difference caused some anxiety as to the dependance to be placed on the observations, in cases where, had the thermometers been suspended side by side, the readings would, no doubt, have been identical. It is a common remark to hear on a frosty morning, "My thermometer registered so many degrees of frost," and another person living close by will say, "Mine registered a greater number," making a difference, perhaps, of three, four, or even more degrees. The cause of such discrepancies in temperature is generally as follows. When comparisons of temperatures are made, no allowance is given for aspect, or for the place where the thermometer is fixed. Now, there is a great difference between the readings of a thermometer on the grass, and of one placed 4 feet above the ground, or again of a thermometer placed on the snow. It was recorded by Mr. Lowe, writing from Highfield House, at the time of the great frost, on the 25th of December, 1860, that a thermometer at 4 feet from the ground was 6°, and another on the grass 8°, below zero; and at Beeston Observatory, one 4 feet from the ground, 8.3°, another on the grass, 11.7°, and another on the snow, 13.3°, below zero.

Again, some thermometers are placed in very sheltered situations—near a window, or where the true temperature is really never arrived at. Others are placed facing the north or the south, and in all cases where there is a difference it can

generally be accounted for by the circumstance that locality, aspect, or position, has affected the reading of the instrument. Sometimes a good instrument in the hands of a novice may from bad hanging read incorrectly, owing to a portion of the spirit becoming detached, and fixing itself at or near the end of the thermometer tube, causing thereby a diminution in the true reading equal in amount to the number of degrees which are in the upper portion of the instrument. And, again, such error may be occasioned by the evaporation, and subsequent condensation of the spirit at the upper surface of the thermometer, a fault which can always afterwards be remedied by placing the thermometer in a position slightly out of the horizontal.

Should an observer have any doubts as to the correctness of the instrument in his possession, it is much better at once to test its accuracy rather than to continue any longer in doubt. A good instrument furnished by a neighbour will give every facility for testing and comparing, and finding out the true readings. Such a comparison is very simple. Plunge both thermometers in water, covering the mercury in the stem, and after an interval compare the readings. If the thermometer whose accuracy is doubtful reads identically with the standard, of course no corrections are necessary; but if there is a difference, the observer knows the error of his instrument, and provides against it accordingly in future readings. Such a plan for testing gives only one reliable degree of temperature; therefore, the comparison should be carried on with water heated to different degrees, so as to correct the instrument throughout the whole scale. An accurate thermometer is an essential to a gardener, and quite as important as good gardening tools. He should be most careful that both for in-door and out-door purposes the instrument be suspended in such a manner, and in such a spot, that he obtain the *true* temperature of the air existing at the place. Fallacious temperatures caused by the bulb being in too close contact with hot-water pipes, or exposed to the rays of the sun, are too often the cause of great mischief in hothouses. A thermometer should be so suspended that the instrument tells its tale truly—viz., the exact temperature of the external air, or the actual heat of the forcing-pit or greenhouse. A good thermometer is one of the greatest boons to a gardener, and one of the best aids to weather wisdom next to the barometer, but without correctness no good result can follow the study of the thermometer, either taken by itself or in connection with the barometer.—X. *Surrey*.

INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS.

We have had much gratification in learning, and the feeling will be shared by botanists and horticulturists generally, that at the Oxford Commemoration, on June 13th, it is proposed to confer the honorary degree of D.C.L. on M. Alphonse De Candolle, President of the International Botanical Congress, and on Dr. Hooker.

We also learn that the Belgian Government, as well as the railway and steam-boat companies, have accorded very great facilities, by the reduction of fares for the transport of passengers and goods by way of Antwerp or Ostend to London, on the occasion of the International Horticultural Exhibition. The Netherlands Government have also accorded a like boon in regard to their fiscal arrangements.

Through the kindness of Dr. Hooker, the Royal Gardens, Kew, will, during the Congress week, be open to our foreign guests at 10 A.M. instead of at 1 P.M. as usual. The Council of the Royal Botanic Society, Regent's Park, and that of the Zoological Society, have also most liberally thrown their respective gardens open to the distinguished foreign members of the Botanical Congress.

PARIS EXHIBITION OF 1867.

A MEETING of horticulturists was held at the Royal Horticultural Society's Garden, South Kensington, on Tuesday last, the 1st instant. Mr. Henry Cole, C.B., presided, and among those present were Messrs. J. G. Veitch, Turner, Laing, Edmonds, J. Lee, Bull, Moore, T. Osborn, A. Waterer, W. B. Booth, &c., and Drs. Hogg and Masters. The Chairman remarked that it would no doubt answer the purpose of horticultural builders to send subjects to such an exhibition as that to be held at Paris, and the object of the meeting was to ascer-

tain if it would be practicable for British growers to exhibit their plants there, and how this might best be done. He understood that it would be permissible to sell the plants exhibited, which might save the cost of transit one way. He further stated that a park of thirty acres would be devoted to this exhibition, and that three acres were assigned to the English, who would be free to erect there what houses and fill them with what plants they liked. Besides, a good deal of ground outside could be planted with subjects for sale. Some discussion ensued, in which Messrs. Edmonds, J. G. Veitch, Lee, Turner, Waterer, and Bull took part, the points mooted being the free transit of plants to the exhibition; its duration; the possibility of keeping a certain space gay with any plants that might be in season, such as Auriculas, Pelargoniums, and other special subjects; and the mode of judging. Several gentlemen having expressed themselves in favour of a continuous exhibition by the removal of plants when their season was over and replacing them with others, the following resolution was moved by Mr. J. Gould Veitch, seconded by Mr. J. Lee, and adopted—viz.,

"That British horticulturists will be happy to accept the invitation of the Imperial Commission to support an International Exhibition of Horticulture for a period not exceeding a fortnight, such exhibition to take place in a special building to be provided by the Imperial Commission, and would suggest for consideration that such exhibition should take place in the latter end of May or the beginning of June."

On the motion of Mr. Turner, seconded by Mr. Laing, it was also resolved:—

"That British horticulturists would be willing to co-operate with the British Executive in exhibiting from time to time specimens of various plants and flowers which may be in season."

A PEEP AT THE WOODS IN ODD PLACES.

No. 3.—THE MANGROVE (*RHIZOPHORA MANGLE*).

"Oh! there's the land!" I exclaimed, as on a bright, warm morning I was standing on the poop of a vessel talking to the captain and looking out for land. The man at the mast-head had sung out "Land ho!" more than an hour before; but the whole of this coast is so low, that it is scarcely visible until one is closely upon it. By this coast, I would have the reader understand that I mean the land at the bottom of the Bight of Benin, at the delta of the Niger, the coast where the chief part of the Palm oil trade is carried on. The place we were bound to was Bonny; and I may here notice that the daughter of my old friend King Peppel, of Bonny, recently arrived in Liverpool, to be educated in England. I need not tell my readers that the Princess Peppel is absolutely a negro; but I can tell them that her uncle, Anna Peppel, the King's brother, who was educated in England, wrote a most beautiful hand, and expressed himself in pure grammatical English, as a note requesting the loan of one of the ship's boats, and which was for some time in my possession, would amply testify. But to return to the particular morning on which the vessel I was in came in sight of the land. We were on the look-out for what is by seamen called the mouth of the Bonny river, but which is really only one of the many arms of the delta of the Niger, and on which the town or village of Bonny stands. Now, the land which we saw was in reality no land, but only trees, for the land here is so low, that in many places, indeed for enormous districts, it is only above water at low tide, and at other times covered or partially covered to various depths with salt water, thus causing a most extensive salt-marsh country. The whole of this marsh is most wonderfully and richly covered with vegetation, and that of a truly tropical character, often being of that fearfully rank and pestiferous nature which, to a mind acquainted with tropical growth, screams and howls aloud "fever!"—fever, that fearful foe which, whether coming as the well-known ague or the horrible putrid fever, is equally painfully dreaded. Almost all the edge of this district is clothed with the Mangrove tree, forming a most beautiful dark green edging, which, at a distance, presents all the appearance of a verdant grass-covered shore, but of a deeper tinge than grass usually possesses.

But we will not keep at a distance, for I want you to see with me these Mangrove woods more closely, for you will find them worthy of inspection; so blow, good breeze, and let us get over the bar, for this is a bar river, and its passage is often attended with a great amount of danger, and when we have seen the trees I will tell you of a serious and painful custom relative to this said bar. Well, we are over; and now while the ship is

going up to the anchorage we will get into the Crew canoe alongside, and go away to look at the trees; but wait one moment whilst I tell you something about this canoe. It is made of a single tree, and, as it will carry four of us, is from 25 to 30 feet long, and about 2½ feet wide. It is tapered at both ends, each end being terminated by a kind of knob or knot, and both are formed nearly alike, at any rate quite sufficiently so to permit of the canoe being propelled either end foremost, though of course it will travel better with one end forward than the other. It is made of a soft kind of mahogany, and is first hollowed out with fire and then finished with a kind of chisel; it is round in the bottom, both inside and out, having no partitions, but merely in the longer and larger canoes sticks or pieces of wood placed across from edge to edge, having holes at each end, which correspond with holes in the sides of the canoe, and by passing bands through which each end of the cross piece of wood is firmly fastened to its corresponding side. The paddles, which are made of a hard, heavy wood, are long-handled and shaped in the blade much the same as an Apple leaf, though very much broader at the base—I mean where the leafstalk is inserted.

Now, let us embark and away to that beautiful grove of trees, and see what we shall find there. In our light canoe we soon reached the trees, and shooting at once out of the bright sunshine into the shade caused by the leafy canopy above us, came all of a sudden into comparative darkness. It was half tide, and looking around, on all sides huge stems of trees with curiously arched roots, disfigured by a thick coating of mud and slime, met the view, seeming like some strange wild dream verified and realised; for these Mangrove trees are tall, straight spars running up to the height of 80, 100, or more feet without a branch, and having roots shooting from the trunk which are frequently as much as 10 or 12 feet long before they meet the mud from which the tree grows, and of a thickness varying from 2½ feet to a few inches. The leaf is small, ribbed, with serrated edges, and somewhat similar to that of the common Alder of England, not at all resembling the general run of tropical foliage, but being more like that of the temperate zone. On the roots of these trees and on the mud at low water are constantly to be seen numerous little fish, which would seem to be almost amphibious, since they exist for a long period out of water, remaining in a perfectly lively state, and swimming merrily away when they again reach water. The pectoral fins of these little fellows are not placed vertically, as in most fish, but horizontally, and so closely together that, spreading out flat upon the mud, they answer the same purpose as the fore feet of animals, and the tail being likewise horizontal the creature is enabled to move on the mud by springing. The head is very large, in shape much like that of the garnet, with enormous eyes; the fish is short and thick, being only from 2 to 2½ inches long, and altogether a most sinister-looking little fellow is this said fish. But I will now tell you of the custom I referred to when speaking of Bonny bar.

This bar swarms with ground sharks, the most terrible and voracious of all the shark tribe, and to give you some notion of their audacity, I will relate a circumstance which occurred during my stay in the river. Some Crew-boys, *i. e.*, natives of the Crew coast, were sent on shore with a canoe, which striking the beach with her bow they all jumped out to haul her up; the water where the steersman was reached half way up his chest, and whilst pushing the canoe to help the others, he threw out his leg to enable him to push with greater force; but during the time he was in this position a ground shark swam at him and literally severed the entire leg, thigh, and a portion of the hip from the rest of the body at one snap; the mangled remains of the poor fellow were immediately conveyed on board the ship to which he belonged, but to no purpose, for he died in excruciating agony in rather less than a quarter of an hour. This will give you some notion of the ferocity of this terrible monster of the deep. Now for the custom. The natives have the utmost fear and terror of these brutes, and to propitiate them, offer on the bar a yearly human sacrifice, thereby hoping to gain their favour in case of any of their canoes upsetting. A young man is chosen whose life, according to their ideas, has been the most exemplary; he then undergoes a year's probation and purification, and becomes *juju*—*i. e.*, sacred. On a certain day he is taken by the priests or *juju* men to the water's edge, clothed in a long white dress made of calico. He is now placed standing in the bows of a large canoe, carrying as many as a hundred paddlers, the canoe being also decorated with white calico. In each hand of the sacrifice a sword is placed, leaning against the corresponding

shoulder, and thus standing, his canoe commences to move a-head of a long procession of other canoes, all of which carry a greater or less number of drummers, who keep up the most diabolical noise with their drums and shouting. In this manner they proceed till they reach the bar, where they all pull up. Here the young man is stripped of all his finery, and forthwith plunges overboard and is straightway devoured by the sharks; the length of time elapsing between his plunge and the water becoming crimsoned with his blood, in consequence of his being torn to pieces by the water demons, being taken as an indication of the greater or lesser acceptability and propitiatory power of the sacrifice.

Let us now turn from this sad and degrading scene in savage life to the lovely works of nature, here to be viewed in all the wonderful luxuriance of the tropics. Here is seen besides the hard, solid, and heavy Mangrove (its specific gravity being greater than that of salt water), a species of bastard mahogany which is soft, light, and porous, though capable of resisting for years the action of the weather, and which is therefore used by the natives of this coast for the purpose of making canoes. Prominent amongst other trees is likewise seen a most splendid tree towering above its fellows in grandeur and majesty, but, alas! like many of the pretensions of the world, apparently but of little use, for the wood is very soft, porous, and spongy, utterly unfit for either building-purposes or any use where strength is required, and at the same time worse than useless for burning. The foliage is large, heavy, and succulent, as is generally the case with tropical trees and plants. The stem is large and noble-looking, several that I saw being at least 5 feet in diameter at a man's height from the ground; the branches are numerous and of proportionate size to the bole; and the whole tree is worthy of admiration as an object of beauty. The bark even of the trunk is smooth and very thick, and so soft as to be easily indented by a blow from a light stick. The first I ever saw I was amazingly struck with, and not being at that time nearly so well acquainted with timber, especially that of the hot climates, as I am now, I imagined that I had fallen in with a grand prize, for I was out with a wooding party and in search of a large stick of timber which I required for a roof-tree for a house. I called out to one of the hands who were with me to come and help me to cut down this magnificent tree, and not waiting till he came up, I thought I would set to work at once, for I carried with me a first-rate heavy American felling axe. Fancy my disgust on making my first underchop, preparatory to making the upper one and bringing out my chip, at seeing my axe-head sink almost out of sight, and finding myself literally splashed all over my chest and face with a thick, white fluid, exactly similar in appearance to milk, or the juice which exudes when the tender green shoots of the Fig tree are fractured. The man I called had by this time come up, and he was so tickled at the softness of the wood and its white fluid, that he began chopping away at the trunk, which was more than 3 feet in diameter. I therefore told him to cut it down, for I wished to see the thickness of the annual rings of so soft-grained a wood, for it was softer and more spongy than the Lombardy Poplar, the specific gravity of which is about the same as that of cork; but I found after all the juice had exuded, and the wood became perfectly dry, that its specific gravity was even less.

Some of the creepers are most beautiful, especially those of the Pea tribe; whilst the eye is constantly attracted by a bright blue flash, amongst the trees and flowers, caused by a beautiful light-blue kingfisher darting from the bough of some bush through the vivid sunlight, as he pounces with unerring aim upon some luckless Landerab, who has most imprudently strayed from his hole in the sand; and to complete the strangeness and discord of the scene, large flocks of grey parrots scream noisily overhead, passing over the river high in air; and huge iguanas and lizards, which here not unfrequently reach 5 feet or more in length, and are held sacred, or *juju*, by the natives, crawl lazily along in the shade of the bushes which come down to the shore, or sleepily bask on the sand, luxuriating in the mild warmth of the sun, whilst the thermometer stands at 98° in the shade.—A SURGEON.

BLEEDING OF VINES.—I have found a simple remedy of my own, always unfailling, which is to apply with a penknife a little cement made into a stiff paste to the bleeding part, first drying the wound with a rag; repeat the process in two or three hours' time and the bleeding will be effectually stopped. —NOVICE.

THE COST OF A STINK.

MANY cultivators have an affectionate liking for a stink. They imagine that a pungent stench given off by a dung-heap is a sure sign of goodness and strength in the manure, and, in fact, they estimate its value very much by the sense of smell. "Ike Marvel" hits off this idea very well in his well-written book, "My Farm of Edgewood," where he makes "Nathan," one of his characters, deliver himself of the following opinions, in conversation with a scientific gentleman. "Guess it's all right; smells pooty good, doan't it?" "Yes, but don't you lose something in the smell?" "Wall, d'n know; kinder hard to bottle much of a smell, ain't it?" "But why don't you compost it - pack up your long manure with turf and earth, so that they will absorb the ammonia?" "The what?" "Ammonia; precisely what makes guano act so quickly." "Ammony, is it? Wall, guanner has a pooty good smell too; my opinion is that manure ought to have a pooty strong smell, or 'taint good for nuthin'!"

The stench arising from manure is occasioned by the escape either of carbonate of ammonia, or sulphuretted hydrogen, or both. These gases are valuable for their fertilising properties, and they are at the same time injurious and poisonous to animal health and life, especially the sulphuretted hydrogen; it not only emits a very disagreeable odour, but is most pernicious to human health. It has even been known to cause death.

Who shall estimate the cost of the stink which at once wastes valuable manure, and injures the health of the cattle and human beings that are forced to inhale it? It would, perhaps, be practicable to make an approximate estimate of the money value of the ammonia that escapes. An ounce of carbonate of ammonia may be bought of a druggist for a few cents. Placed on a plate before a fire, it will, if pure, evaporate in ten or fifteen minutes. This may give some distant notion of what is being lost, hour after hour, as the sun lets down his rays on the manure-heap, stables, and sheds, in the warm weather of spring and summer. Even in winter the loss is very great.

There is no excuse for this extravagance, because it is so easily prevented. The free use of gypsum, earth, and other absorbents, about stabling and manure-heaps, will prevent waste, and preserve health. In view of a probable visitation of cholera in the coming season, the cost of a stink may be terrible. Not only in towns and cities, where large numbers of persons are collected, but even in country places, and on every farm, this nuisance ought to be abated, and every possible precaution taken for the maintenance of the public health.—(*Canada Farmer*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the principal summer crops are now planted, attention will be necessary to keep up a proper succession of vegetables. To do this requires some forethought, and it is scarcely possible to lay down rules for guidance considering that so many circumstances are involved. The wetness, or the reverse, of particular localities, and the texture and capacity of soils for resisting drought, are, however, the principal causes which require consideration in keeping up a continuous supply; such information, we need not say, is only to be obtained on the spot by actual experience. *Broccoli*, this is an excellent time to make a principal sowing of all the late and spring *Broccolis*, such as Portsmouth, Sulphur, Dwarf Late White, Knight's Protecting, and Somers's Late White. The last is one of our very latest *Broccolis*, it succeeds all others, and forms a link between the late spring *Broccolis* and the hand-glass *Cauliflowers*. Proceed with the pricking out of young seedlings, also young seedlings of Brussels Sprouts, Savoys, &c., as they become large enough to handle, likewise *Celery*. Some of the most forward of the early-sown *Cauliflowers* and *Cabbage* plants will now be in a fit state for final transplanting, which should be done at the first favourable opportunity, and in the event of dry weather prevailing, they must be kept well supplied with water. *Leeks*, transplant from the seed-bed as soon as they are large enough in rows 18 inches apart, and 9 inches plant from plant; the soil cannot be too rich. *Lettuces*, tie up for blanching a few of the largest Bath Cos that have stood through the winter; these should be kept well supplied with water in order to induce rapid growth, which is essential to the production of that tender crispness so prized in this variety; keep up successional sowings. *Peas*, continue to earth up and

stake, but previous to earthing-up let them be well thinned out if too thick. This is a more important consideration than is generally imagined; we often sow thickly in order to insure a crop, but if all that come up are left to stand they will grow, certainly, and bloom, and produce a number of small pods, but after a gathering or two they are done; whereas if well thinned out we get a greater weight of finer pods, and they will continue to grow and bloom so as to produce a succession. One of the chief merits of that excellent pea the British Queen is that it continues to produce in succession like a Kidney Bean, and why is this, but because being a large strong-growing sort cultivators are accustomed to give it so much more room? The same principle is applicable to other varieties. *Potatoes* which are coming up should have the ground well and deeply forked between the rows. *Radishes* will now require to be sown very often in small quantities. *Scarlet Runners*, sow full crops of these and of *Dwarf Kidney Beans*. *Turnips*, keep up successional sowings.

FRUIT GARDEN.

Proceed with the moderate disbudding of Peaches, Nectarines, and Apricots. Plums will now require a share of attention in this way by removing all the foreright shoots from the young wood, taking care not to leave more than can be kept well nailed in without crowding. Continue to remove all superfluous wood from Vines. Stir the surface of the earth well among Strawberry plants; have ready a well-prepared piece of ground for planting out all the forced Strawberries as they are brought from the forcing structures; they will produce strong runners for the next year's forcing, and the crops the next year from those left in the ground will be superior to any grown in the usual way; the plants will require several applications of water after planting to give them a fair start.

FLOWER GARDEN.

The late rains will be favourable for recently-planted shrubs, and now that the soil is damp, no time should be lost in completing whatever in the shape of planting or bedding-out young nursery stuff remains on hand. If not done previously the herbaceous ground should now be well cleaned and neatly raked over; this cannot well be done sooner in consequence of many species being late in vegetating. Fill up vacancies either from the reserve ground or by sowing annuals in the intermediate spaces. Large plants of some genera, as *Phloxes*, *Asters*, &c., generally throw up too many flowering shoots; where such is the case thin them out at once, so as to obtain not only fine heads of bloom, but increased strength in the remaining shoots, to enable them to need less assistance from stakes. *Hollyhocks*, for late blooming, may still be planted, as it is better, where they are grown extensively, to plant at two or three times so as to insure a succession of bloom. These showy plants are admirably adapted for planting in long lines and parallel to straight walks, walls, &c., where they produce a grand effect. One of the principal points in pleasure-ground scenery is the beauty of the turf, which should be kept at all times closely cut if perfection is aimed at, but more particularly at this season, when by frequent mowings, cutting the grass as low as possible, the foundation of a close-bottomed turf will be laid for the season. On poor, sandy, or rocky soil the verdure must be maintained by occasional waterings with liquid manure, or dressings with guano, &c.

GREENHOUSE AND CONSERVATORY.

As soon as the cold frames and pits become clear of bedding plants they should be occupied with young stock of hardwooded plants, for the summer growth of which they are better adapted than large houses. Such places will also be found suitable for dwarf *Lobelias*, *Salvia splendens*, *S. gesneriflora*, and many other things which are generally grown for flowering in the conservatory in summer and autumn, indeed most plants which require only a moderate temperature will be more manageable here and thrive better than in lofty houses with double the attention. As early-flowering New Holland plants go out of bloom they should be treated in the way most favourable to secure compact growth, placing them in an airy part of the greenhouse. When the buds have fairly started will be the time for shifting such as require more pot-room, as they can then be kept somewhat close for a fortnight to encourage a free root-action without incurring the risk of the buds breaking scantily. No tribe of plants is better adapted to keep up a constant display in the conservatory than *Azaleas*. Many of the Indian varieties are remarkable for brilliancy of colour, whilst the hardy Belgian kinds are favourites on account of the agreeable fragrance. The treatment recommended for the *Camellia*

to cause it to produce flowers in winter, is in the main applicable to the Indian Azalea. Forcing into wood betimes in the spring, a trifling amount of check to induce it to form flower-buds, and partial rest for a considerable time before excitement, are the main features requiring attention. The Azalea, however, will stand more heat than the Camellia and less shading. Those intended for flowering next January and February should be forced into growth without delay. Let Ericas and the various hardwooded plants inclined to grow straggling be frequently stopped whilst growing freely. Let all the exhausted stock of Cinerarias be cut over successively in order to favour the development of suckers for next winter's flowering. They may be cleansed with tobacco if foul, and removed to a cold frame until the end of the month. Shift on Balsams and other tender annuals. Pot off Achimenes, and repot, where necessary, Gloxinias, Simingias, &c. Put in a stock of Chrysanthemum cuttings for autumn display.

PITS AND FRAMES.

Encourage Cucumber plants for the ridges, let them be kept near the glass where they may have abundance of air and light to cause them to become sturdy, stiff plants for turning out. The ridge should be placed in a sheltered situation. The method of preparing it is as follows:—Dig out a trench about 1½ foot deep and 3 feet wide, fill up with well-fermented materials to 2½ feet in height, cover the whole with about 1 foot of light rich soil, then mark out places for the plants at 4 feet apart, on which place the hand-glasses; turn out the plants when the mould becomes warm, give them a little tepid water around the hall to settle the earth, and cover with the glasses.—W. KEANE.

DOINGS OF THE LAST WEEK.

If "changes are delightful," then may we islanders be happy and contented. Up to Friday week the weather was what might be expected in June, but a closeness in the atmosphere and a falling barometer told us that ere long rains would come, and they came so softly and warm on the Saturday afternoon, that all bedding plants, whether under glass, or mats, or canvass, planted out or potted, were freely exposed to its influence, the rain with the warmth being so much better than any application from the water-pail. One great advantage of the Cranston system of building glass houses, would be the possibility of so managing the planes of glass that they might be made to stand vertically when so desired. It is almost impossible to secure all advantages by any one mode of structure, or any one mode of conducting operations. He is the prudent and the wise man that makes the most of his circumstances, without vainly sighing after other circumstances and appliances which he cannot obtain. We should be afraid to state the very little that the simple fixed roofs of our orchard-houses cost, as if let alone they would have been less than Mr. Rivers stated in his "Orchard-House;" and that was cheap enough in all conscience. That book and the curate's five-pound greenhouse, amazingly tickled the public, who had come to the conclusion that the smallest glass house must cost them at least from fifty to one hundred guineas. In running a good chance of rheumatism from luxuriating in the delightful rains of the Saturday afternoon, and having everything that would stand it freely exposed to such sweet watering, we could not but regret that the fixed squares of the orchard-house could not all stand up vertically to allow the warm fluid drops to fall all over the trees and plants in the house. As the next best we could do for them, we had them syringed, that they, too, after so much fierce sun might know something of the moist balmy air that envelope I everything out of doors; but the syringe at best is only a compromise for the gentle rains. On any other night but Saturday we might have left the most of things uncovered; but, though warm, the veering of the wind to the north told us the rains might become colder, and then there would have been much shutting up and covering on Sunday morning. All covers, therefore, were replaced; and it was as well, for on Monday morning we had a severe frost, with ice the thickness of the sixteenth of an inch on shallow water, and leaves of Geraniums, &c., that touched glass or cloth coverings were slightly blackened, though no injury was done to the plants. That frost, as we expected, has been followed by heavy rains, hail, sleet, and snow, just sufficient to remind us that the weather of July is not to be expected in the first days of May.

KITCHEN GARDEN.

Planted-out Cabbages, pricked-out Cauliflower for succession,

made the nets more secure where seeds of vegetables were sown. Scattered wood ashes on the ground to keep slugs, &c., at bay. Our netting is too small to let birds through; but though raised above the ground and fastened at the sides, Radish seed, &c., near the sides can be obtained by their sitting on the stretched net and sending their bills through the openings. All the Peas, sown three times, having gone to feed the pheasants, planted out a number of rows from semi-circular drain-tiles, the Peas being from 2½ to 3 inches in height, staking them at once as soon as planted. Of course, this takes up a deal of time, but we hope we shall thus secure a crop.

A kind correspondent tells us how he secures all his crops from all kinds of birds, and two-footed and four-footed game, by a number of "trained cats," and of this we will have something to say ere long. By his system, with plenty of cats, the crops of vegetables and fruit may be pretty well secured, even though the game have access to the garden, or to its immediate precincts, as the game must be stupid indeed to let the cat catch them when so much under control, whilst its seen presence and activity, and freedom of motion over a defined space, will frighten them and keep them at bay. In times gone by we derived, as respects birds, similar advantages from hawks that could not fly far, until the birds became knowing enough to perceive the hawks could not catch them, unless they were culpably careless and stupid.

We noticed a few flowers on Dillistone's Early Peas out of doors open on the 1st of May. These, too, had been transplanted. Pods are swelling on some of the same age planted out in the front of the orchard-house, and allowed to run over the ground as they like. Tom Thumb, in pots, in the earliest orchard house, and from plants turned out, yielded a good gathering on the 1st, and might have been gathered earlier, and the plants are densely clothed with pods swelling fast. We never had Tom Thumb so strong, and it is just possible we may have used Sutton's Tom Thumb in mistake; but as there is a row of that in the late orchard-house just coming into bloom, we shall be able to perceive if there is much difference.

All Peas under glass require plenty of water, and a syringing overhead also does them good, or they are apt to eather than when they are grown out of doors. A little clear soot water also improves their crispness. Beginners that grow Tom Thumb should bear in mind to gather before the pods are at all large, as the young peas lie flat in the pod. In answer to an inquirer who is an epicure in one thing, and that is pea soup, and who would have it of the Green Pea flavour every day in the year if he could, but has only a little heated greenhouse to help him, we would advise his sowing boxes of Peas in his house from October to May, thickly, just as he would do Mustard and Cress, and cut them over when 2 inches high, and slice the plants small, and use them as Green Peas. These make a capital substitute for those who are so fond of the young Pea flavour.

Unlike Peas, we always think *Dwarf Kidney Beans* are sweetest and crispest when grown under glass, unless, indeed, when gathered out of doors in warm showery weather in July and August. A row in pots is knotting for bloom in the orchard-house, and they will enable us to clear them all out of the Peach-house, and also from a pit where they have been long bearing. Sowed a lot in boxes and in five-inch pots, five Beans in a pot, which will be transplanted as they are without breaking the balls, except a little disengaging of the fibres outside.

Potatoes.—We planted a lot more, but were stopped by the heavy rains, which made our ground anything but kindly to work. Drew a little earth over the forwardest tops out of doors in case we have another Monday's frost. The most of our supply for the table as yet has come from pots; but two frames of two lights each are ready. Took the frames off them, and protected by hurdles placed over them at night, and merely resting on pots set at back and front. Gave plenty of air, except in these cold nights, to a wide earth pit where the tubers at one end are about fit for use. A little litter, leaves, and rotten dung were placed below the frames, and a little soil on the surface, and in these half-hardy annuals will be set from Melon-frames or pricked out, and at least one frame of good stout plants of early Celery. A great number must be pricked out, with a little shelter out of doors, as soon as we can get time and opportunity. There is no danger of early Celery bolting if it is never allowed to have a check. It suffers more from being checked before it is finally planted out than is generally imagined.

This moving about so easily gives a great advantage to frames

over pits, as what was grown under them may be protected by something more simple than glass, and the glass and box be removed for another purpose. The glass that is used for Carrots, Turnips, &c., may be dispensed with in a few days, and, therefore, though fixed roofs are by far the cheapest, we could not get on well in limited space and with limited conveniences without moveable frames and sashes. We would be afraid to say how often some of our two-light boxes have been moved and made to serve different purposes in a twelvemonth. A good deal of the same system is pursued with glass that covers a brick pit, the sashes being placed over earth and turf pits, with merely a rail on each side on the ground to prevent the sashes resting on the earth. Sowed more Onions and the main crop of Beet, Salsafy, and Scorzoneria. The Onions succeeded the Celery, which was taken up and packed in an out-of-the-way corner in a heap of furnace ashes, where it has kept very good. We think it keeps all the longer when lifted with good balls in March. A late bed that was never earthed-up, thus treated, and well banked with ashes, will come in well for soups before the earliest of this season's sowing comes in. Though bolted a little, if white, it will do for that purpose much better than what is young and green. Early Celery, however, may be had very early if there is room and labour power. More than half of the difficulties of the gardener in half the places in the country arise from so much being expected, and from such little means and resources.

FRUIT GARDEN.

With the exception of syringing a single tree with quassia water, and taking out and thoroughly washing a small tree in a pot, our work in the orchard-house has been merely keeping a look-out for insects, caterpillars, &c., a few turned-up leaves appearing on a forward Plum tree. For want of anything more handy we put as much soot as could be held between the thumb and three fingers on each tree pot in the orchard-house, and watered it in with a rose watering-pot. As soon as we have time and opportunity we will water one-third of the ground with drainings from the dunghill, getting over all the ground at three times, at something like a week's interval.

Expecting these lean-to orchard-houses to be continued, we made a small border in front of one of them (the earliest), and planted Vines 5 feet apart, so as to let in light to the back wall. These, cut back well, are breaking very strongly, and showing many bunches at every eye. A walk goes in front of the house, and our intention was to have made the under part of the walk some day into an extended border, and convert that orchard-house into a late vinery, as our other houses are rather flat-roofed. With the steeper roof of the orchard-house late Grapes could be kept well into April, and these could be succeeded by early ones in a pit. Of course we are aware that ultimately these Vines will have to be sacrificed, or the plants as standards and dwarfs on a trellis in front of the house will have to be done away with, except in the openings between the Vines. However, it is easier taking out than putting in. Any simple mode of heating would keep such a house of Grapes safe in winter, and such kept Grapes will ever be more economical than early forced ones.

Peach-house.—*Strawberries*.—Tied in a number of shoots, and will require an evening or a morning to do so effectually, and expose the fruit more thoroughly to the sun and air. This house must also be more or less thinned of Strawberry-pots. For early work we set the flowers here to a great extent, and move them elsewhere to swell and ripen. Most places in permanent cropping are becoming too shaded for this purpose, and therefore we shall fill some lights in a pit thinly, taking them from the orchard-house where they are showing bloom, but where they would be too dark to set well and have good flavour. The flavour question renders it now unsuitable to gather fruit from under the shade of Vines. We obtained some fruit from the back of a Cucumber-pit, fully exposed on a shelf to the sun; but we have removed the shelf, as the moisture was too much for the flavour; and if the air was all shut off in a cold night some of the ripest were apt to damp in places before the berry was fully ripe all over. It always goes against the grain to be under the necessity of gathering a basket of forced Strawberries shortly after the pots have been watered, as they neither carry so well nor eat so well. At the back of pits, such as those filled with Beans, there was no fear of damping, but being close to the wall on a shelf there was such danger of hardening and burning the fruit in the late bright weather, that we ran a brush coloured with soot water along the wall above the plants, to lessen the reflection of the light and heat. There will be less likelihood of this in a pit filled with Strawberries, and the

sun has now gained such an altitude, that there will be plenty of direct light to set, swell, and flavour the fruit.

As we fear we shall scarcely have enough of Strawberry-pots, most likely we will take up a lot of young plants, planted on a border on purpose, now throwing up their trusses. Part of these we shall hit with balls, and plant in a bed with heat below them, and part we shall pot singly in six-inch pots, and plunge the pots in a mild hotbed out of doors, with the tops of the Strawberries exposed to encourage roots reaching the sides of the pots before the plants are in bloom. We may calculate on its being fully five weeks before we gather fruit out of doors, and though the last-planted-out plants look well, we notice that some that have been two and three years in the ground are patchy from the excessive wet of the winter and the frosts in spring. We may here also add, as respects forced Strawberries, that though they like a variety of manure waterings after the trusses show, we prefer clear water after the berry begins to colour.

Fig-house or Pit.—We went over the most of this in a shady day, exposing the fruit to the light to a certain extent, as a little shade from the leaves prevents burning and scorching, removing lots of extra shoots, and stopping the points of those intended for the second crop. When much of this has to be done, let us advise beginners to put on some of their east-aside clothes, and partly, at least, to cover their faces and hands. Much of this work had to be done by getting beneath the roughish wildish bushes with face, brow, and hands pretty well exposed to the droppings of the milky juice, and notwithstanding our care, and a state of skin which rarely festers from cut or tear, the viscid juice managed to raise some ugly blisters on our brow and hands. Of course, when trees are trained to a wall or trellis, there is less likelihood of the juice hurting the operator. For ease in managing and fertility in cropping we prefer under glass the somewhat rough natural style of growth, with the tying of a shoot now and then, so that it may not rob its neighbours of light. We mention about the juice the more particularly because a lady gardener last season had her hand spotted and blistered. The bad effects generally soon pass away, but the juice leaves ugly stains on black cloth and black silk, and indeed on cloth of all kinds.

Vineries.—We have had a good deal of work in these of late, thinning Grapes morning and evening, regulating the second vinery, and commencing thinning bunches, and regulating and thinning shoots in the late vinery. In the second vinery went over several times in the sunny days the bunches in bloom, slightly shaking, brushing, or drawing a clean dry hand over them, beginning at the top and passing along the bunch. We have found nothing to equal the dry hand in a sunny day, and a temperature of from 70° to 80° and onwards. Where pollen is at all scarce, a piece of white paper may be held in one hand below the bunch, and thus the pollen of one kind plentiful in fertilising-dust, will help to set another kind where the pollen is deficient. By such simple means we have rarely failed in setting Dutch Sweetwater, Black Muscato, Black Damascus, and the different kinds of Muscats when we grew them. A man may thus go over the bunches of a large house in a short time. On large bunches of Muscats this may have to be done several times, as the shoulders will sometimes be in bloom before the points.

In the late vinery, we managed in the dull day of Tuesday to raise Vines nearer the glass, and to stop most of the fruiting-shoots. It is of little use stopping too soon when growth is desired, and the Vines have more room than ours. These Vines had been suspended about 2 feet or more from the glass, have now been raised to from 15 to 18 inches from it, have broken every eye almost, and never had a syringing, and possibly will never have water on the leaves and fruit until the Vines are washed after the fruit has been cut. Our water is so far from pure that we lessen syringing. We have just cleared this house of Pelargoniums, and not too soon, as they were becoming a little drawn, and we must keep the conservatory a little closer in consequence to suit them for a few days.

ORNAMENTAL DEPARTMENT.

On this we can say nothing further this week, than that we have been very busy with bedding plants, giving them a little protection, in fresh arranging plant-houses, conservatory, &c., removing lots of Cinerarias and Primulas, taking Camellias, Epacris, &c., done blooming, to the vinery; and in placing Azaleas where they will be best seen and a little shaded, Pelargoniums where they will have more light, and Fuchsias where they can have more light still. Many things will be freshened up a bit, and be brought back again when in full

bloom. Potted-off Balsams, Amaranths, &c. The change in the weather enabled us to do much work, which we could not attempt in such scorching days, when from morning to night there was a continuous demand on the watering-pot and the syringe. One thing required more labour and material—the furnaces; when the bright sun left us we were obliged to fall back on more coke and coal.—R. F.

COVENT GARDEN MARKET.—MAY 5.

VERY few remarks are called for this week in connection with our market, except to notice the large quantities of Cucumbers now raised, we may safely say 50 per cent. more than will supply the demand; and the importation from Holland having just begun, it will tend to lower the prices still more. Continental supplies are well kept up, and now include Cherries.

TO CORRESPONDENTS.

. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MADRAS RADISH (*M. K.*).—It is a variety of, but the same species as *Raphanus caudatus*, or Tailed-podded Radish. The pods, however, are very much shorter. The Madras Radish has assumed an altered form, probably from being long cultivated in a different climate. *R. caudatus* is a native of Java, where its pods attain always a length of between 3 and 4 feet, trailing on the ground. The natives call it Moogree.

EUPHROM ODOBATISSIMA (*Hilbon*).—We know of no such plant. *Euphonia hirtelloides* is the nearest name at all like it, and the plant to which it is applied belongs to the Natural Order Rosaceae, and is a native of Brazil.

PEACH TREES SHEDDING THEIR BLOSSOM (*A. H.*).—If the wood was strong, most likely the want of ripeness has something to do with the flowers dropping. Extra dryness, or extra wet would also cause it, and so would extreme dryness followed by a thorough watering at once after the buds were swelling. We knew of a similar case years ago, where every blossom fell from want of air during a bright sun, but there is no reason for supposing that to be your case.

GLADIOLUS CULTURE (*J. J. S.*).—The season is now too far advanced to make any observations on the Gladiolus to be of service, but if you will look at page 101 of the present Volume, you will there find all the information you need.

GROWING TOBACCO (*J. Farr*).—We have said all that we know upon the subject. We should have no hesitation in growing as much Tobacco as we needed for fumigating our own plants; though doing so might not be strictly legal.

PELARGONIUMS RUNNING TO LEAF (*Amateur, Totness*).—The running of your young Pelargoniums to leaf is due to your liberal treatment, which is good for old plants, but large pot-room and rich compost are apt to cause a preponderance of shoot and leaf. A less rich compost, and not too much pot-room, are better for young plants. It is now late to stop them, but you may do so, but do not cut them back to one eye or they will bloom very late and be poor. Stop them, therefore, now by merely pinching out the points of the shoots, and they will, if nicely trained, make nice plants for blooming in July and August. They will do better in a cold frame after May, and if in eight-inch pots will not require potting, but give weak manure water once or twice a-week. Afford abundance of air, keep near the glass, and guard against green fly.

ESCHYNANTHUS SPLENDENS CULTURE (*W. H. W.*).—It requires a compost of very fibrous brown peat two-thirds, and one-third very turfy loam broken with the hand; to this add one-sixth each of charcoal broken from the size of a pea up to that of a hazel nut, and silver sand, and thoroughly incorporate. Good drainage is essential, not less than one-fourth the depth of the pot. The plant should be trained as a bush, putting in stakes 2 feet or 3 feet in height, and after the shoots reach that height allow them to hang loose. Shoots will be produced plentifully from the bottom, and these must be staked, for the plant, so far from being a climber, is of pendent habit, looking extremely well as a basket plant. Do not stop the shoots, nor cut away any of the old wood, except where dead, but when the shoots reach the tops of the stakes allow them to hang loosely as already stated. In spring encourage growth by an increase of temperature and a constantly moist atmosphere, being careful not to over-water and yet afford a plentiful supply whilst the plant is making new growths; but after the growths are made keep rather dry at the root, and expose to light and air, for on the well ripening of the wood depends the flowering. In winter the plant should be kept dry at the root, and have a dry atmosphere. A temperature of 50° in winter is ample, the soil and atmosphere being dry, and, when growing, a temperature of from 65° to 70° by night, and 5° to 90° by day with sun, is desirable. It blooms from the points of the shoots and the axils of the leaves at the upper part of the shoots.

ROSES AFTER BLOOMING (*Reader*).—The plants that have been forced and of which the blooming is over should be continued under glass, well hardening them off before exposing them out-doors, and then plunge them in an open situation. The shoots may be reduced to eight leaves if longer, and they may grow at will until September; then stop the plants if required, pruning in the end of October or early in November if you intend to force them. They would be better of a year's rest, or if forced in alternate years.

PELARGONIUMS, STOPPING (*Idem*).—If you stop the shoots of the Pelargoniums now showing for bloom, they will flower at a later period, but not so well as if they were left to themselves, for this is their natural season of bloom. Your stopping will retard the bloom beyond that. They will, however, bloom well.

PLANTS FOR BEDS (*G. H.*).—If you merely wish to fill-in the open spaces between the permanent plants, then you could not have anything better than those bedding plants which delight or thrive in dry, hot, poorish soil. Of these, *Petunias* do well, as also do the different varieties of *Tropaeolum Lobbianum elegans*; *Gazania*, *Cineraria maritima*, and *Geraniums* would do well, but the soil would not suit *Verbenas*, *Calceolarias*, and *Lobelias*. Of permanent plants, *Commelinea caulescens*, *Astragalus aurantiaca*, which you have; *Anomala crenata*, *Asplenium Versicolor*, *Aselepis tuberosa*, *Erodia cicutaria*, *Cistus ladaniferus*, *C. roseus*, *C. ledon*, *C. purpureus*, *C. ladaniferus*, and *C. algarvensis*; *Centaurea maritima*, *Daphne encorura*, *Dicentra spectabilis* and *D. cucullaris*, *Dracopis alatum*, *Erodium richardii*, *Euphorbia portlandica*, *Galium griseum*, *Linum flavum*, *Gladiolus byzantinus* and *G. communis*, *Hemerocallis fulva*, *Horminum pinnatum*, *Lagurus ovatus*, *Linum monanthum*, *Emothera macrocarpa*, *C. taraxacifolia*, *Panicum maritimum*, *Phlox frondosa*, *Plumbago larpena*, *Salvia argentea*, *Scabiosa grandiflora*, *Stachys lanata*, *Trichonema bulbocodium*, *Verbascum in variety*, *Zephyranthes candida* and *Z. rosca*. These last are mostly herbaceous perennials, and may be had as plants at moderate prices from most nurserymen.

HOLLYHOCK LEAVES SPOTTED (*W. a Subscriber*).—The leaves are badly blotched, and this, we think, from frost. There are also traces of a fungus or mildew, and this if the same as we were some time ago pestered with, will yield to a dusting of the leaves with fresh slaked lime. Water in summer with manure water. We applaud your soil is light.

BLACK ANTS (*A Constant Reader*).—Sprinkle guano, or pour ammoniacal liquor from the gas-works over their nests and runs.

GOLIATH STRAWBERRY (*J. H.*).—It is usually called Kitley's Goliath, and can be supplied from Mrs. Nicholson's, or any other nursery where Strawberries are cultivated for sale, and are advertised in our columns.

HOLES IN INDIAN-RUBBER TUBING.—The Indian-rubber tubing of an American garden engine, which has been in use for two or three years, is wearing in several places into a multitude of small holes, which are rapidly increasing by the jet. Is this normal? Is it owing to the action of the water? Could it have been prevented by any mode of taking care of the tube? Ought it to be answered and stowed away during winter when not in use?—P. H. G.

PLANTING GERANIUMS IN ROSE CIRCLES (*W. M. S.*).—Planting Geraniums in the small circles in which there are standard Roses, will impoverish the soil, and interfere with the well-being of the Roses; but if you keep the soil rich by top-dressings of manure and copious manure waterings, you may have plants in the circles without injuring the Roses to any considerable extent.

ACACIA DEALBATA UNHEALTHY (*A Lady Subscriber*).—We think that the brownness and fall of the leaves must be caused by the soil not being kept sufficiently moist, or bad drainage would produce the same result. The ill appearance of the foliage might also arise from a deficiency of light and air in proportion to the heat. The growths, judging from that sent, are very weak. Is the house well ventilated, no plants on the roof overshadowing the Acacia, the soil free, suitable, and well drained, and the temperature not more than sufficient to keep out frost?

PLANT FOR WALL OF CONSERVATORY (*Idem*).—Of the plants which you have, *Plumbago capensis* would be the most suitable. We do not know of any more suitable for a hot wall in a conservatory than *Bougainvillea speciosa* and *Luculia gratissima*.

WAGES AND PRICES IN AUSTRALIA (*John Lawrence*).—We have made inquiries of a reliable authority, but we shall not have replies until at least six months have passed.

SYRINGING PLANTS IN TOWN GARDENS (*R. W. S.*).—Syringing the foliage of plants in town gardens is very desirable, as it frees the leaves of dust and sooty deposits to a great extent, and tends to lessen the evils consequent on the excessive evaporation or exhalation to which plants in towns are liable from the dryness of the atmosphere. A good syringing, therefore, in the evening of hot dry days will, in a great degree, neutralise the bad effects of a town atmosphere on plants.

TULIPS COLOURLESS (*Sidmouth*).—We can only attribute the want of

colour in the Tulips to the soil being very rich, made so most likely by heavy dressings of manure. One thing is certain, the plants are in that exceedingly vigorous condition which induces double flowers. Would you kindly favour us with particulars of soil and cultivation practised, and the name of the variety? Surely it is of the Parrot section, and that known as Belle Jaune, or *Tulipa lutea* major.

DOUBLE VIOLETS (*R. R.*).—The flowers were too much withered to form any opinion of their merits. Could you not send a plant for the Floral Committee to examine and report upon?

NAMES OF PLANTS (*P. I. Newton*).—*Passiflora princeps* (*G. Smith*).—*Asplenium trichomanes*, *Hymenophyllum Wilsoni*, *Fegatella conica*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 5th

DATE.	BAROMETER.		THERMOMETER.				Wind d	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RAILWAY CHARGES.

Amongst the many who have supported Mr. Hinton's indefatigable exertions to obtain a reduction of charges, I have failed to observe that any poultry association through any one of its officers has given any advice or opinion upon this important question. Now, I think that opinions should be obtained as far as practicable from different poultry committees, or, to bring the matter into a smaller compass, I should say through the secretary or chairman, who themselves are able in many cases to give a vast amount of information upon this subject. My own opinion is that all poultry committees throughout the kingdom should take up this matter with a determination to use their best endeavours to obtain a uniform tariff of railway charges. I am led to believe if they did, that in many cases of failure success would attend their exertions. It really is a matter equally for the full consideration of the promoters of shows themselves as it is for exhibitors; and I may suggest to Mr. Hinton the consideration of obtaining committees' opinions, and further, in forming deputations to any railway company, the desirability of selecting gentlemen who represent some of the principal shows—say one-half should be composed of exhibitors and one-half of promoters. If some such plan as this were adopted I feel assured that success must attend the labours of those who are desirous of seeing this evil of excessive railway charges reduced to a uniform scale. I can only add, I should be at all times pleased to assist in promoting such a result, and to give any information desired upon as subject which all poultry-keepers must feel a great interest in.—*PHILIP WARREN, Hon. Secretary of the Hampshire Poultry Show, Southampton.*

PROPOSED POULTRY SHOW IN GLOUCESTERSHIRE.

It has long been a matter of remark amongst all poultry exhibitors that so few poultry shows have been held in the south of England. This remark I have repeatedly seen expressed in the columns of your Journal by correspondents. To these correspondents and the southern breeders of poultry I would address this letter, as concerning them and their interests most nearly.

I propose with their assistance to institute a poultry show in a town of Gloucestershire. The circumstances connected with this undertaking I will briefly but plainly class under headings as follows:—

1st, There is a sum of money required, say £40, to begin with. This, with the amounts received for entries and the admission of visitors, will be sufficient to allow of tolerably liberal prizes being offered, and to pay the expenses of a country show, such as I would propose.

2ndly, I will undertake the whole of the correspondence and arrangements of this proposed show, and I have no doubt as to its success if proper care be exercised.

3rdly, It would be well if those who feel inclined to assist me in the attempt would communicate with me at the address below as soon as possible. With their assistance I have no doubt this project of a poultry show in Gloucestershire can be brought to a pleasant and most successful issue, although at first it appears an arduous task.—*W. B., Journal of Horticulture Office, 171, Fleet Street.*

HOMOEOPATHIC TREATMENT OF DISEASE IN POULTRY

The German "learned" poultry fancier, Dr. Gauss, a follower of Nolan in many respects, treats at great length on disease in poultry. It is quite a study, but in several cases, after enumerating all manner of remedies, he mentions a way of curing disease in poultry after the fashion of the celebrated Hahnemann, the first discoverer in the realms of homoeopathy. The suggestion may be worth a trial, the physic prescribed being easily procured from any homoeopathic chemist.

In "cold in the eye," one or two doses of aconite have been attended with the best result.

In "inflammatio epidemica" (of the vent), a dose or two of *unx vomica* has been of speedy effect.

In "the pip or thrush," he ridicules the scraping of the tongue, and recommends a few homoeopathic grains of "spongia" as a medicine, which would cure the bird without any operation becoming necessary.

Nothing is said in regard to the way of feeding during the treatment, except to abstain from stimulants.

So far homoeopathy. He says in other respects, "In Germany the swelling of the crop is cured in a few hours by simply rubbing the tongue at night with salt, and giving the bird some pieces of garlic to eat. By swelling of the crop is not meant the hardening of it, but its swelling caused by fluid matter, akin to roup." I treated Crève Cœur fowls in this way, and restored them entirely within two days, repeating the experiment no more than once, their crops having swollen to the size of a man's fist. He gives a caution also against coffee-grounds, thrown away near a sink, as a deadly poison to poultry.

Lice are immediately expelled from the plumage of poultry and Pigeons by letting a few drops of turpentine-oil run through the feathers down from the neck.

Birds suffering from the "worm" [gapes?] are effectually cured in Germany by dipping a few pieces of bread in spirit of turpentine, and forcing them down the throat. The turpentine is absorbed into the system, and destroys every worm without fail. "But," the author continues, "above all, separate a diseased bird at once from the others, and

let it have its full liberty on grass land. There it finds medicine prepared by nature, better than any human help can procure."—F. B.

NOTES ON PIGEONS.—No. 1.

FORMER ENGLISH WRITERS ON THE SUBJECT.

DANIEL GIRTON.

FOLLOWING "The Treatise of A.D. 1765," came the still better known "New and Complete Pigeon Fancier, by Mr. Daniel Girton, of the county of Bucks." This gentleman had a greater love for a lengthy title-page than even the author of "The Treatise," and he had in addition a pleasing self-complacency in regard to his literary labours. He thought highly of his work; this shows that he enjoyed his authorship—as he rounded his sentences he was pleased with them. He says in his title-page (and title-pages are usually, like prefaces, the part of a work last written), that his book is "An useful, instructive, and sure guide to Pigeon-fanciers in every sphere of life, comprehending all that is necessary to be known in the whole fancy of Pigeons." He tells us in his preface, that "the most indefatigable pains have been bestowed to make this treatise equally beneficial and curious!" and that "without flattery or deception he offers to the public the best, the cheapest, and most useful work on the subject ever yet published in the English language." "A Daniel had indeed come to judgment," in his own opinion without doubt, and I am not sure but that he was right, although he should not have praised himself, as our copy-slips told us at school. Self-complacent Daniel, in the title-page, in the preface, and in the body of the work, still praising yourself for looking back upon the part finished! Daniel says, "Having presented my readers with a copious, useful, and entertaining natural history of the Pigeon." Comfortable-minded, self-congratulating Daniel! sitting under the Beeches of Buckingham-hire, feeling certain that on the Pigeon subject you had done your duty.

I have said that Daniel Girton's book followed "The Treatise," and soon after I am pretty sure, but how soon I am, alas! unable to state. I have what I think is a copy of the first edition. The spelling is old, the word fancier spelled thus, "faneyer." The type is poor, and the paper very coarse; indeed, more impure paper to print on can scarcely be seen anywhere. At the bottom of the title-page I read, "London: Printed for Alex. Hogg, No. 16, Paternoster Row," but date I find none. My copy has been closely bound, and a portion of the bottom of the title-page was cut off in the binding. Under the words just quoted I can trace the upper parts of some figures, or letters, but there is not sufficient left for me to be able to make them out. If they are a date, perhaps some one possessing a first edition will kindly furnish me with it.

Girton's book has, I fancy, found far more readers than either "The Columbarium," or "The Treatise." The work has been printed again and again; five-and-twenty—no, eight-and-twenty-years ago (how time flies!). I had a copy lent to me then just bought new. Soon afterwards I saw another, and in 1842 I bought a new copy in Bristol. They were in paper cases, and exactly alike, and like the one now lying before me. Self-complacent Daniel was scarcely just to other people. Unlike the nameless author of "The Treatise," he does not say his work was "compiled," but he calls it "new." Oh, Daniel! this was not quite right. Even when he speaks of his book being "embellished with a set of engravings, elegantly executed from drawings accurately taken from life," if he implies that these were done for him he is hardly correct, for with simply the frontispiece of skinny cat and supplicating mouse notoriety excepted, and the over-gay Mottle, we have merely the old cuts of "The Treatise." The pictures in Girton are printed altogether as a frontispiece to the work, opening out like a map in a school geography. Here we have again the dumpy Powter, the unraucous Fantail, the Almond over-carpet, the inelegant Carrier, the charming Jacobin, and the Trumpeter, &c., all feather for feather like those in "The Treatise." Then when we come to the matter, especially the descriptions of the varieties, we have much of "The Columbarium" and "Treatise" over again, with the sentences a little altered or their order changed.

Girton's "Fancier" is closely printed, and contains 140 pages, and appears to have been well known by even those who were not fanciers. Thus Southey in that curiosity of literature, "The Doctor," mentions, if my memory does not

deceive me, this very book of Girton's, devoting a whole chapter to it.

Although not wholly an original work, yet, I think, there are many good reasons to show that the fancy were wise in accepting it as the standard book on the subject during many years. It was portable, cheap doubtless, and better arranged and more complete than either "The Columbarium" or "The Treatise." Girton is the first writer on fancy Pigeons who gives us the natural history of Pigeons generally. He writes of the Stock Dove, the wild Pigeon, and the Turtle Dove, thus being naturalist and ornithologist as well as fancier, and so commending his book to lovers of birds. He writes, too, pleasantly enough. Then he speaks of the Dove-house Pigeon and its habits, and gives us an anecdote of a farmer who complained to a gentleman of the injury done in his fields by that gentleman's Pigeons, and getting the reply—"When you see them trespassing pound them." Upon which the farmer steeped some peas in an infusion of *oculus indicus*, which peas the Pigeons ate, and soon lay lifeless on the field. The farmer picked them up, put them into an empty barn, and gave the gentleman notice that he had taken his advice and pounded the Pigeons. This first chapter of Girton especially is pleasant reading. Then follow full directions for keeping Pigeons for profit, building their cote, stocking it, laws relating to Pigeons, and methods of preventing them leaving their home; all this, including forty-eight pages of useful matter not in either of the former books, and though not meant for fanciers, yet very instructive, and almost every one begins by keeping common birds, and after a while grows into a fancier.

These useful pages having been given, Girton remarks, page 18—"Having now given full and plain directions for the choice and management of those Pigeons that are most advantageous for country people, or others who breed them for the market, we shall now turn our thoughts to gratify the taste of breeders who delight in the fancy birds." Girton also introduces to our notice two varieties not before mentioned, the Smiter and the Chinese Pigeon. In describing others he not infrequently gives us additional matter. Indeed, Moore was improved upon by the author of "The Treatise," and Girton improved further. If we cannot quite grant to Girton that his book is "new," yet we willingly allow that it was more "complete" than its predecessors. Some may say concerning these three old books, Moore was an originator, the writer of "The Treatise" an improver, Girton a completer, he producing a compendium which was for many years the book for Pigeon fanciers. Some years ago I was in the habit of buying every book on Pigeons that I saw advertised. Many times did I foolishly spend my money; some smart handbook arrived, at the best it was old Daniel Girton over again, much curtailed indeed; or it was evidently compiled by some one who had never kept Pigeons, and with pictures by those who were not fanciers. Buy and burn—this was my plan. Then those excellent books for boys containing a description of all the amusements suited for youth. In these works there were usually a few pages devoted to Pigeons; but if old Girton was not followed as he was in "The Boy's Own Book," a dearly-loved companion of mine in my school days, the information was meagre and valueless.

I have now finished with the writers on this subject of the eighteenth century, and shall next proceed to those of the present one.—WILTSHIRE RECTOR.

DRAGON PIGEONS.

MR. LUDLOW says he was induced in the first place to promote discussion upon the respective qualities of the two sorts of Dragon under notice—viz., those with the blue rump and those with the white rump, so that your readers might judge whether or not it was folly for me to exclaim against the latter without reason or argument. Now, I contend that there is no room for argument as to the relative properties of the two, simply because the one is clearly right and the other egregiously wrong; the one worthy the attention and admiration of the fancier, the other only fit to be consigned to the shop of the poultener.

The superior colour which Mr. Ludlow says the white-rumped birds possess—namely, the light blue, is not at all in favour of the Dragon, which is, or should be, of a totally different blue to the Owl or Turbit. Moreover, when the light blue is found it is almost invariably accompanied by a white beak, equally as objectionable and worthless as the white rump.

Mr. Ludlow goes on to say I came forth without evidence in support of my fancy. Not so. I have offered to refer the matter to Mr. Esquilant, a gentleman well qualified to offer an opinion, from his long experience not only as a Dragon breeder but as a Dragon fancier. But lest Mr. Ludlow may think that Mr. Esquilant is the only gentleman in the fancy to whom I am willing to refer, I beg to mention the names of Mr. Bellamy, Mr. Carroll, Mr. Else, Mr. P. Eden, Mr. Kidpeth, and Mr. Betty, any or all of whom, I am sure, will be willing to point out to Mr. Ludlow the error he has fallen into.

Blue Dragons, Mr. Ludlow goes on to say, are understood to be white-rumped, that it is the exception to obtain them otherwise. I admit that the common white-rumped birds may be obtained much more readily, but surely this is no argument in favour of such being perfect or correct; on the contrary, it only goes to show, as I before stated, the difficulty in breeding to perfection the Dragon as well as all other birds, for where one perfect bird is reared there are fifty imperfect and valueless. What, I ask Mr. Ludlow, would he think of a white-rumped Red, Yellow, or Black Dragon? If consistent or correct in the Blue, he cannot surely disclaim it in other colours.

Mr. Ludlow says he knows of one pen of white-rumped Blue Dragons which have taken fifteen prizes. If this be so, I can only say there must either have been an absence of blue-rumped birds or a great want of discrimination on the part of the judges.—JONES PERCIVAL.

[Here this passage of pens between Mr. Percival and Mr. Ludlow had better close. Each abides by his opinion. We shall be glad to hear, however, from any or all of the gentlemen named by Mr. Percival what is their opinion on the question.—Ens.]

THE MEMORY OF BEES.

I AM able to confirm the statement of your pagan correspondent ("THE BLACKBETHAN"), a week or two ago; having had a very similar case, but extending over a longer period. It has been so repeatedly said that the winter sleep of bees impairs their memory of localities, and allows of their safe removal to a new stand, that I resolved to try the experiment. A strong hive had been unusually quiet all the winter, only turning out on exceptionally fine days, and this I determined to move into an adjoining garden should the opportunity serve. Accordingly after nearly three weeks of cold weather, during which not a bee stirred out, I effected the removal very quietly. This was on the 3rd of March, and for eight days more the bees remained prisoners. On the 11th, being a fine bright day, they were out sunning themselves, and a few went back to the old place. The same thing occurred on the 17th. This I had expected, and I was prepared to lose two or three hundred bees; but, although the numbers were never large at any one time, they continued to visit the place up to April 15th, six weeks after the removal of the hive, and nine weeks after their last flight on the old spot. The hive is now rapidly recruiting, but it has received a check which I did not expect, and I shall have too much respect for the memory of bees to repeat the experiment.—F. H. WEST.

THE TOMTIT A FOE OF BEES.

If the large tomtit is alluded to by your correspondent "R. S." of last week, I reply it is an inveterate enemy to bees in the winter season. On visiting some years ago a friend who kept bees, we noticed a bird of that kind at the apiary, and on closer inspection observed that he came a second time and tapped with his bill at the entrance of one of the boxes, and after waiting a short time knocked again, when one of the guards rushed out in a great rage with wings erect, and was instantly picked up and carried to the branch of a neighbouring tree, from which we noticed the wings of the bee fall upon the snow underneath; and shortly afterwards, the visit by that or another was repeated with a similar result. My friend, being a good shot, stood guard himself, and soon bagged several of the enemy.—Wm. GOODSALL.

EARLY SWARMS.—A swarm of bees came off on the 27th of April. The hives belonged to a blacksmith in a village near Hayward's Heath, Sussex. On the same day I saw some

drone enter one of my hives.—H. D. HARRISON, *Mytlen-Cuckfield, Sussex.*

OUR LETTER BOX.

SENDING FOWLS TO THE ANTIPODES (*Amelia*).—We are unable to give you the exact dimensions of the coop you will require, because you do not state the breed of the fowls you are about to send. Cochins, Borkings, and Brahmas require almost as much again as Hamburgs or Game. The coop must be high enough to admit of a perch; the front closed all but one-quarter space, which should be square and in a corner opening on the water vessel, and affording the means of feeding. The coop should be raised 6 inches from the deck, to allow water to run under instead of through it, and the roof should have a fall to the back of 3 inches to get rid of any water that falls on it. The flooring should also slant from front to back, and there should at the back be an opening of an inch for the facility of cleaning out. If the rise from back to front be 2 inches, the fowls will do part of the cleaning themselves by scratching.

HENS EATING THEIR EGGS (*A Lady*).—Hens will sometimes eat the eggs placed under them, but it is a very uncommon case. It unquestionably arises from a diseased state of body. The habit, however, seems to take such hold of them, that we always advise they should be killed. We recommend you to put a good heap of dust, road sand, and black sulphur—two pounds of the latter to a bushel of the former, close to their sitting place, and before you entrust good eggs to a suspected hen put her on some hard composition ones, at which she can peck till she is tired. Better still, put such a one on none at all. If you have no sitting hens, buy some in the neighbourhood. If they come from a cottager, so much the better. These unnatural appetites generally arise from over-feeding, and that is a complaint to which cottagers' fowls are not subject.

FOWLS SUDDENLY ILL (*Black Bantam*).—It would seem as though your fowls ate something injurious to them. Wherever there is the distention of the crop with the fluid you mention there is disease at work, although the bird may go on for days without showing it. There is inward fever and consequent thirst. This induces inordinate drinking, and lays the foundation of fatal disease. It is not uncommon. The most successful treatment is to purge freely with castor oil, then to feed sparingly on bread steeped in milk if the bird is strong, and on strong beer if it is weak; but the most essential point is to confine them, so that they shall not have access to water. There is no cure while they can have an unlimited supply of drink. They may be allowed a little water three times per day, but when they have seafully drunk it must be taken away. The treatment is helped if the patient be held up by the feet till the crop is empty.

EGG BROKEN AND THEN HATCHED (*H. B.*).—Your man is clever and has his poultry wits about him. The operation of pasting paper over the hole in the egg has been performed before, and we have seen an egg containing a live chicken patched up in all directions. We hope he was wise to the end, and assisted in bringing the duckling into the world, as assistance is generally needed after these accidents. Failing this, the chick dies in the shell. It is a very common mistake for people to forget that Ducks sit longer than fowls.

HEN LEAVING HER EGGS (*Harriet*).—Leaving them for an hour, especially at the very commencement of sitting, will not have the slightest ill effect upon their hatching.

FOOD FOR A CARDINAL (*H.*).—Give it Canary, rape, millet, and hemp seed mixed, but not too much of the latter; and in a separate pan place some oats, German waste, and a large quantity of bread crumbs mixed with it. Keep also the food which the bird has been accustomed to in the cage, it being rather a difficult bird to keep any length of time in confinement. It will pine away, probably, if its regular food be altogether withdrawn. Try for a change a little fine dust, mixed, as to be rather stiff with cold water. The fits and posness have most likely been brought on by not having a change of food. Vary it about once or twice a week.

CANARIES (*J. S. D.*).—You can have Brent's "Canary" from our office post free, if you enclose nineteen postage stamps with your address. You might do worse than apply to Mr. Walters, Bird-fancier, Hyde Street, Winchester.

FRAME HIVES (*T. A. Weymouth*).—We believe no frame hives are more simple and efficient in working than those devised by our correspondent Mr. Woodbury, and named after him.

LIGURIAN BEES (*M. S., Pritham Place*).—The dead bees had all broken loose from their moorings before they reached us, so that it was impossible to identify them. One or two were fairly marked, but we cannot undertake to give any opinion as to the purity of a Ligurian stock from the examination of a few dead specimens.

BEES MISTAKING A HIVE FOR THEIR OWN (*A. S.*).—In your two hives standing together in a wooden house with separate entrances, the bees of which on returning from their work on entering the house are sometimes attacked by several others and killed—this evil arises from the returning bees mistaking their hive, and will probably diminish, if it does not entirely disappear, as the season advances and the bees become more active. It is, however, a very serious evil in spring, and we should suggest as a palliative adding a porch to one of the entrances, which might also be painted a different colour from the rest of the bee-houses.

POULTRY MARKET.—MAY 7.

A good supply, and dull trade.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 66.1°; and its night temperature 42.9°. The greatest heat was 85°, on the 17th and 17th, 1833; and the lowest cold 25°, on the 15th, 1850. The greatest fall of rain was 0.50 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

APPLE AND PEAR TREES IN ORCHARDS.

VENTURE to send you a few lines on the recent discussion which has taken place in your pages on the subject of fruit-tree culture, not with any wish to re-

open the controversy, as it is not in the least my intention to enter into the arena with two distinguished gladiators like Mr. Robson and Mr. Rivers; for though I can hardly regret the controversy when it has elicited so much information on the subject, I still cannot help regretting that a mere difference of opinion on the merits or demerits of any particular method of the propagation or culture of fruit trees should cause a warfare, even on paper, between those who really have but one common interest at heart. I am afraid, however, that "our Chaplain" will think I am trespassing on his province as Mentor to "our Journal." I will, therefore, only now add that my object in making these remarks on the recent discussion is to call attention to the fact that, with truth on both sides of the question (as there undoubtedly is), still the old adage, "*In medio tutissimus ibis*," is true in this particular instance, as in my humble opinion it always is. Put any old saying to the test, there is none which is so universally true as the one of the golden mean. Neither homoeopathy nor allopathy, neither the do-nothing nor the do-too-much system is true, but the practice of the clever physician is the only one which stands the test of common sense, and it is to help Nature to restore herself. As in medicine so in horticulture, the object of the cultivator is not to thwart Nature, but to assist her; not to teach Nature, but to let her teach us. Now, I do not pretend to set myself up in opposition either to Mr. Rivers or Mr. Robson. I am fully aware that they both know a great deal more than I do on the subject, and have had far more experience. I merely wish to take a common sense and practical view of the question, and do not wish to enter into a minute discussion as to the best or perfect way of growing fruit, but to draw attention to the most generally practical way. Apples and Pears are so essential in every family, both for the kitchen and the table, that it really is an eminently practical question; and there is hardly any one who has a kitchen garden who is not interested in the question, "How to obtain most easily a supply of fruit that shall be good in quality, fair in quantity, and not require too great an outlay."

Mr. Rivers is so accustomed to the management of fruit trees, more especially under one method of cultivation, that he does not see difficulties, or thinks nothing of them, which would be great difficulties to the generality of cultivators; for, though Mr. Robson may have over-estimated the value of an acre of Apples or Pears grafted on the Paradise and

Quince, and planted a yard apart, yet I think it would be hardly possible for any gentleman or amateur to plant the trees, or even to plant the stocks and graft them where they stand, at less than 6*l* a-piece, which would make an outlay of about £120 an acre (at a yard apart every way), so that even if it be granted that this system of dwarf and small trees is the best, yet the first outlay is so great as to put it quite beyond the reach of the generality of cultivators.

On the other hand, the system of planting standard trees on grass land at 10 yards apart, leaving the grass to grow over the roots of the trees, and the trees to grow as they like, is really no cultivation at all.

What I would advocate is the bush and espalier systems, both for Apples and Pears, not placing the trees too closely, but planting them in rows, leaving open spaces or plots of ground for vegetables between the trees, according to the size of the garden or the number of trees which may be required. I would in this way have double lines of espaliers wherever the walks are, and grow the trees which are planted in the other lines as bush trees. If the subsoil is bad root-pruning will be necessary, or rather it will be advisable to prevent any too roots running down into the soil; but otherwise, by judiciously forking and manuring the ground, and by not cropping too near to the trees as they grow, they will be induced to push their roots to the surface, and these will come upwards for their supply of nourishment rather than run downwards, and there will be no necessity constantly to lift or transplant them.

Again, as to pruning, a yearly shortening of the summer's growth in the spring of the following year, and an occasional thinning during summer of any growths that may be too luxuriant, will be quite sufficient, the object being not to dwarf or stunt the trees, but to keep them in a compact and bush-like form, and to make them fruit down to the ground. By leaving open spaces for vegetables between the rows plenty of light and air is admitted, and the trees make healthy and strong stems, instead of being drawn-up and spindly. Of course the requirements of different gardens vary so much that it is difficult to lay down general rules; but I am inclined to think, on an average, that bush Apple trees should not be planted at less than 8 feet apart, and Pear trees at 6 feet, leaving a space of from 8 to 10 yards square between the rows, or more, at the option of the planter. Trees treated in this method will, in eight or nine years after planting, yield from five to ten pecks a-piece. I sold last year from two Pear trees adjoining each other in a row of this kind, one a *Bonne D'Inde*, the other a *Van Mons Leon Leclore*, which had been planted eight years, five pecks of saleable Pears from each tree, for which I received 4*s* a-peck. I do not, however, quote the price as thinking the market value of fruit any real criterion of their worth, except, perhaps, in the case of market gardeners, or nurserymen, or any persons who grow a great quantity of fruit for sale, because the size of fruit is much more considered in the market than the quantity; besides, the object of most persons in growing fruit is to supply their own table, and to grow a sufficient quantity of each variety to be able to furnish either the

dessert or the kitchen with plenty of each variety of fruit as it comes into season. I do not wish, therefore, to allude to the cultivation of fruit for commercial purposes, but for the general use of gentlemen's families.

The same system is, I think, however, equally adapted for the gardens of the poor, because the space taken up by the trees is not great, and yet at the same time they soon come into bearing, and yield heavy crops. The quality of the fruit, too, is far superior to that from ordinary standards, and, as far as my experience goes, it keeps much better. I am not by any means pretending to advocate anything new, as this medium system, if I may call it so, of growing bush fruit is one that is now extensively adopted in many gardens. I do not wish to now enter upon the question of wall fruit, because it is not often that really good walls can be given up to Apples and Pears; moreover, I wish to confine my remarks chiefly to orchard and garden fruit grown in the open ground.

I have had a very marked instance of the comparative growth of bush trees in a kitchen garden where the soil was annually forked and manured, and of trees planted in an ordinary orchard. Nine years ago I planted some bush trees in my kitchen garden, and at the same time filled up some vacant places in an orchard. In the latter instance the trees were left alone, and the grass allowed to grow over the roots, and, I am obliged to confess, little or no care taken of them. The soil, however, is very good loam, 3 feet deep, with pure dry sand underneath. At the end of nine years, however, I may safely assert that the bush trees that have been annually pruned in, and the soil around them properly cultivated, are capable of bearing ten times more fruit than the orchard trees. Practically the crop has been more than a hundredfold greater, as I have never picked more than a dish from any one of the orchard trees, and several of my bushes have borne yearly from five to seven pecks a-piece.

As we have had for the last four years a very extensive collection of Apples and Pears sent for exhibition to our York-shire Pomological Society, having had upwards of a thousand dishes of Apples and Pears last year at Whitby sent for comparison, not only from Yorkshire, but from many different counties, not for the sake of competition for prizes, but in order to ascertain what are the best sorts for the north of England, and also the best method of growing them, I have had a very good opportunity, as one of the Committee of the Society, of examining and comparing fruit grown in different ways and from a great variety of soils and climates; and I have been amply confirmed in my opinion that fruit from bush trees does not suffer by comparison with fruit from pyramids, dwarfs, or espaliers, either in size, quality, or flavour. I think decidedly the best general collection of fruit shown last year was from some young bush trees about from five to seven years old. If young trees are over-pruned at first it is necessary to root-prune as well, in order to prevent the disposition to make nothing but wood shoots. I have found not only in trees under my own care, but by observation in other gardens, that where trees are too much pruned when young, instead of inducing them to fruit early, it retards the period of fruiting— unless, of course, Mr. Rivers's system of lifting and transplanting is adopted. No doubt, for Mr. Rivers's own method of cultivation this is the only plan; but I think it so contrary to nature thus to check the supply of sap and to thwart the growth of trees, that it would not be expedient to adopt it except under peculiar circumstances. What I would again repeat is, that in the hands of an experienced cultivator like Mr. Rivers such a method will no doubt succeed; but I have seen rows of small trees treated in this way in some of my friends' gardens, when two or three hungry schoolboys would have cleared the rows. We must bear in mind that amateurs do not plant these trees by the hundred or the thousand, but perhaps will plant ten or twelve, or from that up to fifty, along the walks of a kitchen garden; and it has rarely been my fate to see a good dish of Apples or Pears on one of these trees for the first five or six years of their existence, after which time they begin to fare better, for root-pruning and pinching-in are gradually left off.

I have little doubt that the Quince stock is the best general stock for Pears, and that much has to be done and learnt yet in the way of double-working. So, too, I agree with Mr. Rivers, that the Paradise stock is most suitable for dwarf Apple trees, and that the most essential of all qualities for stocks is that of surface-rooting; but I still contend that if the ground on which fruit trees are planted is properly forked and manured, mulched if necessary during the winter, and forked, not dug,

in the spring, the tendency of fruit trees will be to make surface roots. Sun and air will penetrate to them, so as to help to elaborate and ripen the sap, and improve the quality of the fruit, and there will be no necessity for root pruning, unless canker or some other disease show that the roots have struck into a subsoil which they do not like.

I do not think it wise, on the other hand, to plant standard trees by way of making a permanent orchard; every orchard, however managed, begins after a certain time to deteriorate; of course, it much depends on the nature of the soil, how long trees may continue to improve, and bear good fruit, but it is far better to replant and be content to sacrifice trees after they attain a certain age; and with the system I would advocate of leaving open spaces, these open spaces might be planted five or six years before the other trees are sacrificed. I fancy, with some few exceptions, that after twenty to thirty years, trees become too large and unmanageable, and the fruit begins to deteriorate.

I dare hardly say much on the *verata questio* of orchard-houses, for fear of bringing a hornet's nest about my ears; but unless on a large scale, and in the hands of very competent persons, they rarely if ever succeed. I confess I have never seen a small one in the hands of an amateur that really answered or repaid the trouble or expense. Small houses are liable to such changes of temperature, such alternations of heat and drought, with cold and moisture, that two or three hours' neglect on a sunny day in April or May may ruin all the care of the rest of the year. No doubt large houses in the hands of such persons as Mr. Rivers, Mr. Pearson, of Chilwell, Rev. T. C. Bréclaut, and others, will answer admirably, but in the generality of cases small houses are pleasant toys, and pot trees are like spoiled children that require a great deal of care and attention, and very often after all but little repay the care bestowed. So I am afraid my advice to those who wish to build small unheated orchard-houses would be like "Punch's" advice to those about to marry, "Don't!"

One great objection in my mind to small pyramidal trees, and very dwarf bushes, is that they are so liable to have their blossoms injured by spring frosts; for though Mr. Rivers is quite right in saying that the radiation from the ground is an essential benefit in ripening fruit on dwarf trees, yet the very same causes bring them into premature blossom in the spring, and I need hardly say that on still frosty nights the nearer the bloom is to the ground the more it is liable to suffer from frost, and the smaller the tree the less protection it has from its own leaves and branches against the radiation of a spring frost. On a still night in May, I have known more than 5° difference between a thermometer on the ground, and one 4 feet off the ground. This often accounts, in my mind, for Apricot trees bearing freely at the top of the wall, while they have but few fruit or none low down.—X. Y. Z.

ROSE MILDEW—FRUITS IN NEW JERSEY.

IN your Number of the 1st of May Mr. Badclyffe repeats the remedy formerly given by him for Rose mildew. If it came from any less trustworthy quarter I certainly should hesitate before I allowed so poisonous a salt as blue vitriol to find its way to my Rose roots. Last year I applied the remedy to the leaves of some Nectarines under glass, and it injured them. I had previously tried sulphur, but that had failed to cure. Strange to say, the only plants affected were Hunt's Tawny, which, although it has glandless leaves, never mildewed with me before. Last year three trees out of four were affected.

The above, at 8 feet apart each way and 22 feet between the rows, would represent about one-quarter of an acre, and would take eighty-eight bush trees.

In the same Number was an interesting letter from New Jersey; but your readers should be cautioned that the Peaches which succeed so well in America on sandy soil, are on their own roots, and not on Plum stocks. I am surprised, however, to hear that Melons attain such perfection on similar soil, as all our cultivators here seem unanimous in recommending stiffish loam. I have, however, heard of Melons succeeding in mere leaf mould.—G. S.

INTERNATIONAL HORTICULTURAL EXHIBITION.

It is quite evident that the vast space of nearly four acres which the great International Exhibition is to occupy will be barely sufficient to receive the collections of plants that are entered; and as the arrangement of such a quantity of plants will occupy an unusually long time, and be attended with considerable difficulty, we would suggest that intending exhibitors of hardy trees, shrubs, and such plants as will not suffer by exposure, should send them in as early this week as possible, so that as much of the work of arrangement as can be done may be got over before Monday, the 21st. Every preparation is now made for the reception of the subjects entered, and the sooner they are delivered the better.

FLOWERS OF THE LAST SEASON.

CHRYSANTHEMUMS.

The ever-increasing varieties of this favourite autumnal flower would seem almost to defy improvement; and yet those who narrowly watch, as only connoisseurs do, the varieties that are produced year after year, are able to see that this improvement does take place, and that, while some of the older flowers still maintain their position, by far the greater number are jostled out of the way by the newer sorts; and in size, substance, shape, and colour, each year witnesses some advance. Mr. Salter still maintains the position he has for so many years occupied as the introducer of novelties in this class of flowers; and the following varieties which I have both bloomed myself and seen at Mr. Salter's, were exclusively sent out by him; and as an aid to purchasers I give the following notes.

Albert Helyer.—A large rosy purplish flower, fully incurved. A fine sort for cut blooms.

Blanche of Castile.—A beautiful clear white, thoroughly incurved, and with broad petals.

Golden Ball.—Bright rich orange, with golden orange back and tips. Fine shape, and beautifully incurved.

Golden Dr. Brock.—Fine rich yellow. A sport of that fine variety Dr. Brock, partaking of its good qualities, but of a different colour.

Hercules.—Very large, reddish carmine. Incurved after the style of Garibaldi, but far superior to it.

Lady Carey.—Large, rosy lilac, with silvery back to the petals. Well incurved, and a fine show flower.

Miss Margaret.—Pure white Anemone flower, with fine centre.

Mr. Brantley.—A large flower of an Indian red, tipped with yellow. A fine flower for cut blooms.

Mr. Wynness.—Violet puce. A fine flower, of rich colour, and well incurved.

Mrs. Kaines.—A blush flower, blooming very late, and of excellent quality.

Pink Pearl.—Pink, with a silvery shade. Well incurved.

Prince of Wales.—Dark violet, shaded. A well-shaped flower, with large petals.

Sam Weller.—Indian red, tipped with yellow. Well incurved and good.

Venus.—Large, lilac peach. A beautifully shaped full flower.

Virgin Queen.—Pure snow white. A plant of good habit, making a fine specimen.

POMPONES.

Golden Aurora.—Bright yellow. Sport of the old and well-known *Aurore Borcale*. Of good habit.

White Trevenna.—A fine sport of *Rose Trevenna*, blooming early, and very pretty.

A good deal has been said as to artificial manures and their effect on the growth of various flowers. Having used Standen's manure during the last season, I can bear witness to its efficacy as a most valuable stimulant. Applied to both Chrysanthemums and Hyacinths, its effects were soon seen; and used

according to the directions sent with it, I have no doubt it will be found equally valuable for other plants; but I only speak of it as I have myself experienced its efficacy.—D., *Dial*.

DESTROYING THE GOOSEBERRY CATERPILLAR.

MUCH has been written, and many directions have been given, as to the destruction of the Gooseberry caterpillar through the columns of this Journal, but I have never seen recommended the means that I have adopted with unfailing success for several years. This consists in dusting every bush with powdered white hellebore as soon as a caterpillar makes its appearance. I obtain it of a chemist at the trifling cost of 1s. 8d. per pound, which is sufficient for fifty bushes. It is very rare that there is any need to repeat the dose, as the caterpillars are found dead on or beneath the bushes the next day. The bushes should be dusted in dry weather, as the rain is apt to wash much of the hellebore off the leaves. I apply it by the means of a common sulphurator. Should any one try it, it will be found effectual.—J. S. S.

[The use of fresh white hellebore powder has been frequently recommended in our pages for destroying the Gooseberry caterpillar. It should be washed off the berries before they are eaten, as it is poisonous.—Eds.]

THE LATE FROSTS.

THE first week in May in this locality will not be soon forgotten for the disastrous effect on vegetation of the blighting frost of April 30th and May 2nd. On the 27th ult. the thermometer registered 65° at 7 o'clock p.m., with a gentle shower of rain. The expansion of the leaf was surprisingly rapid, and the atmosphere was suffocating. On the 30th at half-past 5 a.m. the thermometer registered 25° Fahr.; but the night previous being dry, this low temperature did not do so much damage, and that was principally confined to the Potatoes, Asparagus, and Cherries. On the 2nd inst. a.m. it registered 24°; snowing all day on the 1st everything was soaking, so nothing escaped. Nectarines, Cherries, Apricots, and Pears were fearfully cut up; Peaches not so much. The Oak and Beech foliage are frozen black. The Ash and other hardy trees in bloom are completely scorched. The Brassica tribe received a severe check.—P. MIDDLETON, *The Gardens, Wynnstay, North Wales*.

GARDENERS, AND THE INTERNATIONAL HORTICULTURAL EXHIBITION.

THE subject of my letter must be my only apology for trespassing upon your valuable space. The great International Horticultural Exhibition is now at hand. Scores of gardeners, who have not the means wherewith to go, would like to be there. As a class of men they are generally expected to be up with the age, and there are very few ladies or gentlemen who like to see their gardeners behind their fast-going neighbours; but this is inevitable unless they have an opportunity now and then of brushing the nap and rubbing off the rust by coming in contact with the most skilful of their order. When we call on neighbour John across the way, who can boast of having filled the same position for thirty or forty years, and has never been away from the place for a day during the whole time, how we smile at his antiquated notions and his old-fashioned stand-still place. His Camellias and Acacias are pot-bound, and he knows it not; his Geraniums, towering up on a single stem, are 3 or 4 feet high, or thrusting their heads through the roof of his house, and he considers this the way to grow them. As a matter of course we set him down as one of the "old school." There are hundreds of gardeners who wish to go beyond our neighbour described above, and who would gladly avail themselves of the opportunity of visiting the great International Horticultural Exhibition; but the fact is they cannot. Their stipends compared with other artisans are low; provisions and wearing habiliments are dear, and the wants of the family are numerous. What is to be done? Let every lady and gentleman who possesses an intelligent go-ahead gardener who is desirous of taking the lead among his neighbours, send him to the great Show and pay his expenses. I fancy some of your readers saying, "That is a capital idea!" And so it is; but it will be better still if it be put in practice. The description and ground plan which you gave us in No. 265

of the 34 acres, to be devoted to a monster show in London of the best and finest productions from all nations—then, too, the congregation of the cream of horticulturists from the three kingdoms, besides numbers from the continent,—why, when we think of all this it makes us long to be there; but when we talk about it in the family circle, our good and frugal wives say, "No, Robert, you must not think of going. Look at the expense of travelling; two hundred miles there and two hundred back, besides staying in London for several days. There is little Mary wants a new frock, Johnny wants boots, and Joseph, who is to be a gardener, has not yet completed his education." And so there the matter has to rest.

But if our good employers would send us, with the means in our pockets to pay our expenses, v hat a fresh tide of life would flow through our services for the future! I am sure, while we enjoyed the pleasure combined with the profit, our employers would reap the advantage.—P. H. B.

ROYAL BOTANIC SOCIETY'S SHOW.—MAY 9.

The first of the summer shows at the Regent's Park was held on Wednesday last, and was honoured with an inspection at an early hour of the day by their Royal Highnesses, the Prince and Princess of Wales, the Duchess and Princess Mary of Cambridge, and Prince Teck. The display, though scarcely so extensive as at the corresponding shows of previous years, was nevertheless very effective, and had a brightness and freshness which gave it a peculiar charm. The weather, too, so important an element in the success of flower shows—or, indeed, out-door gatherings of any kind, though by no means promising in the morning, became favourable in the after part of the day, enabling the visitors to promenade in the grounds and listen to the lawn to the Life Guards' bands.

STOVE AND GREENHOUSE PLANTS.—Of these, numerous collections were shown, but the plants generally were not sufficiently forward to have reached their full perfection as regards bloom. In collections of ten, Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, had among others a large bush of *Tetralæa cærulea* covered with bloom; *Chorozeina cordatum splendens*, fine; *Cyrtocoma reflexum*, *Pimelea Hendersoni*, *Hedera fuchsoides*, and *Eriostemon intermedium* and *nerifolium*. Mr. J. Wheeler, gardener to J. Philpott, Esq., Stamford Hill, exhibited in the same class *Meliniella magnifica*, *Chorozeina varium nanum*, and *Epaeris nitida splendens* in excellent condition, *Boronia serrulata*, *Azalea Triumphantis*, &c.; and another collection came from Mr. G. Wheeler, gardener to Sir F. Goldsmid, Bart.

Collections of eight were shown both by nurserymen and amateurs. Among the former Mr. Rhodes, Sydenham Park, had a large specimen of *Hedera fuchsoides* in fine bloom, a most excellent example of *Dracophyllum gracile*, by far the best in the Show; *Chorozeina cordatum* in fine bloom, *Eriostemon intermedium* and *nerifolium*, a fine plant of *Erica Cavendishii*, *Erica depressa*, and *Aphelaxis macrantha rosea*. From Messrs. Lee, of Hammersmith, came *Gompholobium polymorphum* splendens with showy salmon scarlet and purple flowers; *Erica verticosa coccinea minor*, in fine bloom; *E. Cavendishii*, a large plant of *Epaeris grandiflora rubra*, *Hedera fuchsoides*, *Stephanotis floribunda*, and *Eriostemon pulchellum*. Mrs. S. Glendinning & Sons also contributed a good collection, in which were the yellow *Azalea sinensis* in fine bloom; *Extranæi*; the white-flowered *Rhododendron Gibsonii* well covered with bloom, but the flowers not individually so large as we expect to see in that species; *Erica suaveolens*, and *Hedera tulipifera*. A collection from Mr. Baxendale, Guildford, included *Chorozeinas*, *Epaerises*, and *Rhynchospermum jasminoides*.

In the Amateurs' class for the same number of plants, Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, had a fine collection consisting of *Epaeris grandiflora*, *Stephanotis floribunda*, in excellent bloom; *Boronia tetrandra* with charming wax-like flowers; *Meliniella magnifica*, with ten spikes of bloom; *Eriostemon linearifolium*; *Adenandra fragrans*, not sufficiently cut; and *Azalea Lateritia*, forming a dense cockscomb-shaped mass of bloom. From Mr. Kemp, gardener to Earl Percy, Albany Park, came *Pimelea spectabilis*, bearing numerous heads of its white flowers delicately tinged with pink; *Boronia serrulata*; the deep blue *Leschenaultia biloba major*; *Diosma speciosa*, and *Chorozeina varium nanum*, in fine bloom; *Ailamaeda nerifolia*, and *Azaleas*. A good collection of eight plants was likewise shown by Mr. Kalle, gardener to Earl Lowther, East Horsley Tower; and one of six, by Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading, comprising excellent specimens of *Chorozeina Thomsonæ*, *Rhynchospermum jasminoides*, *Aphelaxis macrantha rosea*, and *Boronia microphylla*.

The mixed collections of flowering and fine-foliated plants also constituted an attractive feature, groups being contributed by Messrs. Lee, Mr. Gill, gardener to Mrs. Bauley, South Lambeth; Mr. Williams, Holloway; Mr. Carr, Mr. Rhodes, and Mr. Young, of Highgate. In Messrs. Lee's collection were fine examples of *Cyathia Smithii*, *Croton variegatum*, *Theophrasta imperialis*, *Aloe-leaved Yucca*, *Hedera tulipifera*, and *Erica verticosa coccinea minor*; whilst in that from Mr. Gill, *Sphagnum latifolia* though not large

was in a very fresh and handsome condition; other plants in the same collection were *Philodendron crinites*, with the leafstalks covered with curly hair-like processes, *Boronia punctata* in beautiful bloom, *Eriostemon*, &c. From Mr. Williams came *Dracæna lineata* and *Zamia pungens*, very large and fine, *Cordylina indivisa*, the variegated *Aloe-leaved Yucca*, *Eriostemon buxifolium*, and other flowering-plants; and Mr. Carr and Mr. Rhodes contributed well-grown examples of *Sphagnum latifolia*, *Alocaasia metallica*, *Pandanus elegantissimus* and *javanicus variegatus*, *Erica Cavendishii*, *Rhynchospermum jasminoides*, *Chorozeinas*, and other flowering plants.

Awards.—For ten: first, Mr. Peed; second, Mr. J. Wheeler; third, Mr. G. Wheeler. For eight: Nurserymen: first, Mr. Rhodes; second, Messrs. Lee; third, S. Glendinning & Sons; fourth, Mr. Baxendale. For eight (Amateurs): first, Mr. Donald; second, Mr. Kemp; third, Mr. Kalle. For six: first, Mr. A. Ingram. For ten fine-foliated and flowering-plants: first, Messrs. Lee; equal second, Mr. Gill and Mr. Williams; equal third, Mr. Carr, gardener to P. H. Hinds, Esq., Byfleet, and Mr. Rhodes.

FLANS AND FINE-FOLIATED PLANTS.—Of Exotic Ferns a fine collection of twelve from Mr. Barnard, gardener to J. Taylor, Esq., Stoke Newington, received a first prize. It consisted of *Cyathia buconensis*, *dealbata*, *medullaris*, *Cooperi*, and *degenis*; *Cyatium princeps*, *Gleichenia spuloneis*, an *Allophila*, the Bird's-nest Fern very fine, *Eleocharis coreocandens*, *Dicksonia nutantia*, and *Todea africana*. A group from Mr. Young, gardener to R. Barclay, Esq., Highgate, was second. Collections of six fine-foliated plants were contributed by Mr. Donald, Mr. Barnard, Messrs. P. & A. Smith, and Mr. Young, to whom prizes were awarded in the order in which their names occur. Among the subjects exhibited in this class were good examples of *Pandanus*; *Alocaasia minor* in variegated form, the large white-splashed leaves of which were very effective; the Bird's-nest Fern, variegated *Crotons*, *Yuccas*, *Dracænas*, *Pteris crotchalliana*, &c.

LEAVES constituted the grand feature of the Show. Such magnificent plants as those exhibited by Mr. Turner and Messrs. Veitch were alone worth a long, a very long, journey to see; and it was most pleasing to observe that though the pyramidal fashion of training had been preserved, the stiff chaotic character which was so much and so justly complained of in past seasons had been in a great degree avoided, and nothing could have been prettier than the few bright green leaves here and sad green leaves there that now and then peeped forth from among the gorgeous masses of bloom which the entire specimens presented. Mr. Turner's eight consisted of Sir C. Napier, Magnificent, Coronata, very brilliant, Optima, Variegata, Globetaster, Juliana, and Conqueror; Messrs. Veitch's of Extranæi, dazzling in colour; Stella, a glorious flower both in form and colour; Herberthii, white, very fine; Criterion; Præstantissima, Iveryana, Coronata, and Cedo Nulla. In sixes the same two eminent growers were main competitors, and Mr. Turner was again successful in taking the first place with a set of plants nearly equally fine with those which he exhibited in the class for eight. They were Iveryana, Gumb, Iveryana, Etoile de Gand, Globetaster variegata, and Holfordii, the last a brilliant rosy purple, and quite dazzling. Messrs. Veitch had Flower of the Day, and Magnificent, white; Holfordii, *Violaæa superba*, *Rosea superba*, and *Empress Eugénie*, all of which were large specimens and in remarkably fine bloom. Collections were also shown by Mr. Rhodes, Messrs. Dobson & Sons, Mr. Penny, gardener to H. H. Gibbs, Esq., Regent's Park, Mr. Gill, Mr. Peed, and Mr. Wheeler, gardener to Sir F. Goldsmid, Bart.

Awards.—For eight: first, Mr. Turner; second, Messrs. Veitch and Sons; third, withheld; fourth, Mr. Rhodes. For six: first, Mr. Penny; second, Mr. Gill; equal third, Mr. Peed and Mr. G. Wheeler. For six: first, Mr. Turner; second, Messrs. Veitch; third, withheld; fourth, Messrs. Dobson & Sons.

ONCIDIUMS.—In these there was a great falling off in the number exhibited, and the fine collections which Mr. Baker, Mr. Wilson, and Mr. Bullen produced in former years were sadly missed. From Mr. Penny came *Dendrobium Dalhousianum* and *macrophyllum giganteum* with four good spikes, the Fox-brush *Aerides*, *Lælia cinnabarinæ*, *Cypripedium villosum* with ten blooms, *Phalanopsis grandiflora* in fine condition, both as regards health and bloom; the yellow and crimson-flowered *Oncidium sarcodeis*, *Lycaste Skinneri*, and a fine variety of it remarkable for the delicacy of its colour, and *Vanda savais*. Mr. Page, gardener to W. Lum, Esq., had his *Oncidium amplatum majus* noticed last week, the rich yellow *Dendrobium densiflorum*, D. noble elegans, deeper in colour than the common variety, *Saccolabium Blumei* with one fine spike, *Cattleya Skinneri*, &c. In groups of eight, Mr. Peed had the *Aerides Faddineii* with two fine spikes, and crispum; *Lælia purpurata*, with nine large and finely-coloured flowers; *Vanda insensis*, savais, and tricolor; the pretty yellow *Oncidium sessile*, and *Cypripedium lobatum superbum*. Mr. Wiggins exhibited *Trochopala crispata* with nine of its pretty blossoms; *Aeride*, *Warreri*, *Vandas*, *Cypripediums*, &c. Collections of six came from Messrs. Lee, Jackson of Kingston, Mr. Rhodes, and Mr. Bull, and comprised varieties of *Lycaste Skinneri*, *Lælia purpurata*, *Oncidium*, *Dendrobium*, *Phalanopsis*, *Cypripedium*, *Vandas*, *Chysis bincetensis*, and the bright yellow *Tulip-like Angulæ* Clowesii.

Award.—For ten: first, Mr. Penny; second, Mr. Page. For eight: first, Mr. Peed; second, Mr. Wiggins; third, Mr. J. Wheeler. For six: first, Messrs. Lee; second, Messrs. Jackson & Sons; third, Mr. Rhodes; fourth, Mr. Bull.

HEATHS.—Numerous fine specimens were shown by Messrs. Rhodes, Peed, Jackson, A. Ingram, and others, particularly of the following—viz., Victoria, Webbiana, Devoniana, profusa, Spenceriana, ventricosa coccinea minor, Hartnelli virus, Cavendishii, affine, depressa, perspicua nana, mutabilis, florida, propendens tubiflora, and Sundryana, remarkably fine. Spenceriana, fastigiata lutescens, vasiflora, and Alberti major, buff.

Awards.—For eight (Nurserymen): first, Mr. Rhodes; second, Messrs. Jackson. For eight (Amateurs): first, Mr. Peed; second, Mr. J. Wheeler. For six: first, Mr. A. Ingram; second, Mr. Kaile; third, Mr. G. Wheeler.

Roses, as exhibited by Messrs. Lane, of Great Berkhamstead, were magnificent pyramids, standing from 3 to 5 feet in height from the ground, and were covered with blooms individually large and beautifully fresh. Such a fine exhibition has not been witnessed for a long time. The sorts were Paul Perras, splendid; General Jacqueminot, very double; Louis Peyronny with about thirty blooms; Anna de Diesbach, very fine; Senateur Vaisse; Charles Lawson, magnificent; Victor Verdier, Coupe d'Or; Souvenir d'un Ami, and Gloire de Dijon. Mr. William Paul also had a beautiful collection, but there were not so many of the brilliant-coloured varieties. It consisted of Juno very beautiful, Beauty of Waltham, Tea Madame Villeroz, President, and Souvenir d'un Ami; Victor Verdier, Paul Perras very fine, Lælia, Madame Damazin, and Anna de Diesbach. Two or three other collections were shown, but nothing to compare with those above mentioned.

Awards.—For ten: first, Messrs. Lane; second, Mr. Wm. Paul. For six: first and second withheld; third, Mr. Terry, Youngsbury; fourth, Mr. Wiggins.

PELAGONIUMS.—Of these there was a fine bank, and owing to the Show being a week later than that at Leighton, the plants were more fully in bloom. For nine Mr. Turner was first with fine plants of Beacon, Lilacium, Cambrlate, Empress Eugenie, Lady Canning, Desdemona, Celeste, Rose Celestial, and Fairest of the Fair, the last two particularly good; and Mr. Fraser, of Lea Bridge, second with Peacock, Beadman, Fair Rosamond, Osiris, very showy, Fairest of the Fair, Empress Eugenie, Rose Celestial, Cambrlate, and Rosema. In the Amateurs' class Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, was first with excellent specimens of Fairest of the Fair, Spotted Gem, Rose Celestial, The Bride, Lilacium, Peacock, Sir Colin Campbell, Fair Rosamond, and Nestor. Mr. Wiggins also exhibited and received a third prize.

Fancy varieties were also well represented in the collections from Mr. Turner and Mr. Fraser, who were respectively first and second. The former had Evening Star, Lucy, Roi des Fantaisies, Undine, Modestum, and Lady Towers; the latter Cloth of Silver, Maroon, Undine, Arabella Goldard, Clara Novello, and Marionette. Mr. Weir, gardener to Mrs. Hodgson, Hampstead, was the only exhibitor in the Amateurs' class, and had a first prize for good examples of Actæa, Carminatum, Queen of Roses, Madame Sontag, and two others.

MISCELLANEOUS.—Mr. Turner, of Slough, again exhibited a beautiful collection of Acanthas, in Indian, Alpine, one of which, John Leech, reddish brown, received a first-class certificate. Calceolarias, well grown and in excellent bloom, came from Mr. James and Messrs. Dobson & Sons, of Leighton; and Pansies from Messrs. Hooper, James, and Kingston; and a seedling called Princess Helena, from Mr. Hooper, received a second-class certificate. Messrs. Cutbush, of Highgate, contributed a number of small neat plants, consisting of Azaleas, Eriostemons, Heaths, Aplexis, and Rhododendron Cunninghami; Messrs. Jackson & Sons a basketful of Cerodendron Thomsoni; Buffourii, a variety with larger flowers than the ordinary form; and Mr. Donald a fine specimen of Lælia purpurata with a score of blooms. From Mr. W. Paul came a collection of Nosegay Pelargoniums, also Little Gem, an Oak-leaved variety, with deep rose-coloured flowers; and Messrs. F. & A. Smith had variegated and Zonale Pelargoniums, among which Magnet secured a promising broad-petalled bright scarlet variety. A similar collection was exhibited by Messrs. E. G. Henderson & Son, who also had Aver palmatum atropurpureum, a neat bronze-leaved plant, and their beautiful variegated Dog's-tail Grass. Mr. Bryant, Hoanlow, received a first-class certificate for Pansy Colonel Murray, maroon on a yellow ground. Certificates of the same class were awarded to Mr. Bull for Selaginella Martensii albo-variegata, Primula intermedia, and Rhododendron Bianca; and second-class certificates for Abundant vexillaria, Peperomia arifolia, Maranta splendida, and Nidularium Plumii, all of which have been noticed in previous reports. Mr. Bull also showed new Petunias, Pelargoniums, Machærum firmum, and other plants. A brace of a large white-spined Cucumber called Champion of the World was also exhibited by Messrs. A. Henderson & Co.

ROYAL HORTICULTURAL SOCIETY.

WEEKLY SHOW, May 12th.—At this meeting Messrs. Cutbush received a first prize for the best collection of miscellaneous plants, and in the class for the best-arranged basket of flowers Messrs. Lacking were first, and Mr. Young, of Highgate, second. Mr. Young received a first prize for a collection of vegetables. Messrs. Cutbush also received prizes for collections of Caladiums, Anacans, and ten pots of finely flowered Myosotis intermedia. Rev. Geo. Cheere, of Papworth

Hall, had a first-class certificate for a highly meritorious exhibition of Giant Mignonette in pots, and another for a remarkably well-grown specimen of Tropæolum Papworth Scarlet.

CRYSTAL PALACE SHOW—MAY 12TH.

On this occasion there was a brilliant and varied display, though perhaps not quite so extensive as last year, a circumstance no doubt attributable to exhibitors holding back their productions for the great International Exhibition. Following so closely after the Show at the Regent's Park, as might be expected, many of the collections which appeared there were again brought forward, and as these have been already noticed, it will be unnecessary to enter into details respecting them.

STOVE AND GREENHOUSE PLANTS.—Among these were remarkably fine flowering specimens of Dracophyllum gracile, various Chorozeumas, Tetrathecha eriophylla, Eriostemons, Epacris, Erica Cavendishii, Adenandra frœnans, Boronia frœnandra, Lyonia, Gnœthyllis, and Vinca alba; in addition to which there were good examples of Aplexis, Diosma speciosa, and Fimbricars. One collection which would otherwise have taken a higher position in the prize list, was placed fourth because it contained a plant of Dentzia gracilis, which, of course, was not admissible.

Some good mixed collections of fine-foliated and flowering plants were also shown, and included Abocasia metallica, the Variegated Alue-leaved Yucca, Croton variegatum, Sphærogyne latifolia, Cyanophyllum magnificum, the Lemon Grass, which emits a grateful odour when burned; a very fine Pandanus elegantissimus from Messrs. Lee, Theophrasta imperialis, the Date Palm, Maranta zebrina, Gleichenia splendens, &c.

Awards.—For sixteen: first, Mr. Peed; second, Mr. J. Wheeler, gardener to J. Philpott, Esq., Stamford Hill; third, Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, Bart., Regent's Park; fourth, Mr. Kemp, gardener to Earl Percy, Albany Park. For ten (Nurserymen): first, Mr. Rhodes; second, Messrs. Lee; third, Mrs. Glendinning and Sons; fourth, Mr. Bayenline, Guildford. For ten (Amateurs): first, Mr. Peed; second, Mr. Kaile, gardener to Earl Lovelace, East Horsley Tower. For six: first, Mr. C. Smith, gardener to A. Anderson, Esq., Norwood. For twelve, fine-foliated and flower ring plants: first, Messrs. Lee; second, Mr. Young; third, Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet; fourth, Mr. Rhodes; extra, Mr. Barraud, gardener to J. W. Taylor, Esq., Stoke Newington.

HEATHS.—Of these several fine collections were shown, and those from Mr. Rhodes and Mr. Peed were especially good. Coccinea minor from the former was noticeable for the profusion of its richly-coloured blooms; and Devoniana, mutabilis, perspicua nana, Victoria, profusa, Spenceriana, florida, vasiflora, and Sundryana, in these and other collections were excellent.

Award.—For ten: first, Mr. Rhodes. For eight: first, Mr. Peed second, Mr. J. Wheeler. For six: first, Mr. Rhodes; second, Mr. C. Smith; equal third, Mr. J. Wheeler and Mr. Kaile; equal fourth, Messrs. F. & A. Smith and Mr. G. Wheeler.

AZALEAS.—In the Nurserymen's classes Mr. Turner, of Slough, again produced his splendid plants, consisting, with but one or two exceptions, of the same varieties as shown at the Regent's Park, and in equally fine condition. Mr. Penny and Mr. Peed also exhibited some neat pyramidal plants of small size; and there was, besides, a class for twelve plants in 10-inch pots, which drew from Mr. Turner a well-flowered collection, consisting of Flag of France, Ivoryana Improved, Elegantissima, Gloire de Belgique, and Madame Millez, all of them white more or less striped; Duc de Nassau, Kinghorn, and Bernard Andrus, bright rose, the last semi-double; President, Mars, and Comtesse de Hainault, shades of salmon, Mars being the nearest to scarlet; and Charles Emle, rose salmon, bordered with white.

Awards.—For eight (Nurserymen): first, Mr. Turner; second, withheld; third, Mr. Rhodes; fourth, Messrs. Cutbush. For eight (Amateurs): first, Mr. Penny; second, Mr. Peed; third, Mr. G. Wheeler. For six (Nurserymen): first, Mr. Turner; second withheld; equal third, Messrs. Cutbush and Messrs. F. & A. Smith. For six (Amateurs): first, Mr. Penny; second, Mr. J. Wheeler; third, Mr. C. Smith; fourth, Mr. Peed. For twelve: first, Mr. Turner; second, withheld; equal third, Messrs. F. & A. Smith and Messrs. Cutbush.

ORCHIDS.—There was a fine bank of these, and the collections of twenty were especially good. Mr. Bullen, gardener to A. Turner, Esq., Leicester, was first with excellent specimens of Dendrobium noble, tortle roseum, albo-sanguineum, and charnum, Odontoglossum neriium, O. cordatum with two fine spikes, Cattleya Aeklandia with four blooms, C. Mossie, Phalaenopsis amabilis and grandiflora, Cypripedium Lowii, hirsutissimum, a pair of C. barbatum superbum with nearly three dozen blooms, variety, of Lycæte Skinneri, Burlingtonia fragrans, Oncidium, &c. Mr. Wilson, gardener to W. Marshall, Esq., Enfield, who was second, had, among others, Dendrobium tortle roseum, forming a pretty mass of flowers, having rosy-lilac petals and sepals, and a white lip; D. chrysotoxum, several Cypripediums, and Phalaenopsis Luddemanniana with four beautiful blooms; and the same Phalaenopsis, as well as P. Schilleriana and Dendrobium Jenkinsi, a very dwarf evergreen species, which is best grown on a block, came from Mr. Robson, gardener to G. Cooper, Esq., Coburg Road, who was awarded a third prize. The fourth went to Mr. Page, gardener to

W. Leaf, Esq., who would have taken a higher position had his collection not contained three Phalenopsis. In other classes there were good examples of the Feathered Arides, Cypripediums Hookeri and villosum, Oncidium sarcoles, and *Laelia purpurata*. For twelve, Mr. Penny was first, Mr. Peed second, and Mr. J. Wheeler received an extra prize; for six, Mr. Penny and Mr. Peed were first and second, and Mr. Wiggins third.

Roses in pots formed a leading feature; for not only were Messrs. Lane's magnificent plants exhibited, but these were reinforced by other fine specimens from Mr. Turner, Messrs. Paul & Son, and Mr. William Paul. Among specimens in 13-inch pots, besides those shown on the previous Wednesday, there were profuse-blooming plants of Paul Ricant, Niphetes, Madame de St. Joseph, Juno, General Jacquemont, Victor Verhier, and Charles Lawson; and in eight-inch pots, of Madame Beauv, Anna Alexioff, Devonensis, Alba rosea, Madame Falcot, Victor Verhier, Beauty of Waltham, and Alphonse Belin. Awards—For ten in 13-inch pots: first, Messrs. Lane; second, Messrs. Paul & Son; third, Mr. Turner; fourth, Mr. W. Paul. For twelve in eight-inch pots: equal first, Mr. Turner and Messrs. Paul and Son. For six in first withlid; second, Mr. Wiggins.

PELAGONIUMS. There was a beautiful bank of these; but as the names of the varieties in each exhibitor's collection have been given in the report of the Royal Botanic Show, it is unnecessary here to repeat them.

Awards—For twelve: first, Mr. Turner; second, Mr. Fraser. For ten: first, Mr. Ward; second, withlid; third, Mr. Wear; fourth, Mr. Wiggins. For six (Amateur Nurseyment): first, Mr. Turner; second, Mr. Fraser. For six (Amateur): first, Mr. Wear.

MISCELLANEOUS.—Of new or rare plants Mr. Bull, of Chelsea, was as usual a large exhibitor, and the collection which he furnished contained many interesting plants, most of which have been already noticed in these columns. First prizes were awarded him for *Litochia tripartita*, a pretty Fern; *Cycas Ruminiana*, *Plonicophorium sechellanum*, and *Pitcairnia tabula-formis*, now producing orange-scarlet flowers; and second prizes for the pretty white variegated variety of *Selaginella Mertensii*, *Bignonia argyrea violascens*, *Bertolonia margaritacea*, *Cestus zelanicus*, with green foliage longitudinally veined with white, and brown on the under side; *Calamus dealbatus*, *Polystichum anulare parvisinua*, *Eranthis mam argyronerum*, *Marrania splendida*, *Ternstroemia nobilis*, the leaflets of which have prominent purple midribs; *Zamia cycadifolia*, *Cycas plumosa*, the white variegated form of *Podocarpus macrophyllus*, *Trospatia splendens* and *granulif.*, *P. ndaune ornatus*, *Verschoffia splendida*, and a pretty white-striped Mince, for a similar variety to which Messrs. Carter also received an award. Mr. Bull also exhibited the Long-tailed Rabbit, *Raphanus candidus*, of which the pods, though not full grown, were at least 16 inches long. *Nothochloa na cretacea*, from Mr. Parker, Tooting, received a first prize; and from the same came also a new variety of *Fraxinea encyema*, very fine in colour, and a small plant of *Aucuba himalaica*, bearing its large berries. Seedling Pelargonium *Sylvia*, from Mr. Turner, of Slough, was awarded a first class certificate; and of tricolor-leaved and other variegated kinds a very beautiful group, containing numerous fine varieties, came from Messrs. F. & A. Smith, of Dulwich, who received a first prize for them. Awards were likewise made to Mr. Turner for beautiful collections of Tulips and Auriculas; to Mr. James for *Calceolarias*; to Messrs. Downie, Laird, & Laing for Fancy and other Panseys; to Mrs. Glenbuming and Sons for cut blooms of *Rhododendron Fortunei*, rosy pink; and to Messrs. Lane for a fine group of *Rhododendrons* similar to those exhibited at recent shows. Several nice tricolor-leaved Pelargoniums were shown by Messrs. Carter & Co., besides the pretty striped Japanese Mince already noticed, as well as tastefully filled plant-cases. A number of these, likewise neatly filled, came from Messrs. Barr and Sugden. A *Diosphenelia* from New Grenada, with dark green leaves mottled with paler green, was also shown by Messrs. Lee, of Hammersmith; *Petunias* in the way of Mrs. Ferguson by Mr. Bull; and Panseys, both in pots and as cut blooms, by Mr. James.

FRUIT.

The show of Fruit was very small. In Pines, of which there were only nine, a Queen weighing 1 lbs. 5 ozs., from Mr. Cameron, gardener to the Duke of Richmond, Goodwood, was first; an Enville, from Mr. Wallis, gardener to J. Dixon, Esq., Astle Park, was second; a Prickly Cayenne of 6 lbs., from Mr. Pizzo, third; and a Queen from Mr. Carell, gardener to J. G. Riddell, Esq., Hermonston Grange, Worskop, fourth.

In Black Grapes, good well-coloured bunches of Black Hamburgh, from Mr. Osborn, Finchley, were first; and the same kind from F. Smith, Tavchenham, also well coloured, second. Mr. Clement, of East Barnet, was third, but the berries were red. Black Proutizman, well coloured, was shown by Mr. Allport, gardener to H. Akroyd, Esq., Doddington Park. Good baskets of Black Hamburgh from Mr. Osborn and Mr. Allport, received first and second prizes respectively. Good bunches of Muscat of Alexandria, and tolerably ripe for this season, were shown by Mr. Turner, who was first for White Grapes; and in the same class a third prize was given to Mr. Endary, gardener to J. Drew, Esq., Hornsey, for Buckland Sweetwater. Prizes were also awarded to Mr. Teag, gardener to the Duke of Newcastle, Clumber, for Royal George Peaches and for White-Marseilles Figs; also to Mr. Hepper, gardener to C. Cannon, Esq., Hampstead, and Mr. Read, gardener to J. Hunt, Esq., Sydenham, for Strawberries. A fine

cluster of Bananas, as yet only partially ripe, was exhibited by Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet, and was awarded the first prize in the miscellaneous class; and the third was awarded to Mr. Hepper, for a very good dish of Falmer's Black speckled Kidney Bean. Scarlet Nonpareil Apples in good preservation were shown by Mr. Allen, Merton Road; and a brace of Harrison's Reliance Cucumbers by Mr. Reach.

The grounds of Rockhills, the residence of the late Sir Joseph Paxton, were on this occasion thrown open to the visitors, a privilege of which numbers availed themselves.

WALL FRUIT, AND OTHER MATTERS.

I SEE BY THE JOURNAL OF HORTICULTURE and other periodicals that the blossoms of wall fruit trees have not set well, and that a large proportion of them have fallen. I have seen the same with my own eyes, both under glass and out of doors. I have lately visited my old and valued friend Archdeacon Huxtable, of Sutton Waldron, near this place; and I find that the wall-fruit blossoms, both outside of and under glass, have fallen almost to a totality. It is the same in two other large gardens near here. This leads me to speak of my three old Peach trees at Rushton, the united ages of which are little short of 130 years. They have borne in nine consecutive years 1563 Peaches; and I have left them with beautiful foliage, without a sign of curl, and they are bearing 377 fine-growing Peaches in their tenth year. They should have borne 437 Peaches to make up the 5000 in ten years; but, as the trees were cut to a true balance much wall has been lost for a time. I thought it best to put them in good form before bidding them adieu; otherwise, though unbalanced, they would have had wood enough to bear the 437.

I have been told since I have been here, that one of these wall-fruit spoilers, jobbing pruners, has said that had he pruned the trees above referred to, he would not have pruned them as I have done. Perhaps not; and I may say that had he pruned them in his fashion (long-fan fashion), they never would have borne in ten years 1940 fine Peaches, nor would they have been so hale and strong as they now are. There ought to be an act of parliament to coerce such men to pass an examination before the Rev. T. Bréhaut prior to their daily journeys to slaughter the wall trees of England. Peach and Nectarine trees, both under glass and out of doors, are with rare exceptions a disgrace to the science of arboriculture; and so they will remain till men study the use of foliage, and the connection and sympathy between the heads and roots of trees.

I have been a short-pruner for years, and I am persuaded that the days of long-pruning are over—it is at least high time. Lofty walls (14 feet, are incidentally the cause of mischief. I have had a wall built here 60 feet long (three sides of a quadrangle, surrounding a greenhouse), and I am now about to build another of 130 feet long with ten-foot wings at each end. The former is 6 feet high, and the latter will be 7 feet high. They are one brick thick, with nine-inch piers 5 feet apart, the plain surface being southwards. The latter wall will not be filled up till autumn. The former wall is filled up as follows:—Galande Peach and Rivers's Victoria Nectarine. These were brought from Rushton, and have been twice moved this spring. The former has dropped all its flowers; the latter has set well, and will have a fair crop. I recommend to novices the following Nectarines:—Victoria, Pitmaston Orange, Violette Hâtive, and Elruge. As my wall was put up very late I had to hustle in trees from the nearest nursery in foliageed state. Besides the above two, I put in Murray and Violette Hâtive Nectarines; and Royal George, Vanguard, two Violette Hâtive, Salway, and Red Magdalen Peaches. I hope I have not made a bad choice. At any rate I was obliged to obtain what I could. Time is money in England, and delays are dangerous. When my 150-foot wall is up I must ask further advice before filling it up. I hope some one will give me a few hints as to a further selection of Peaches and Nectarines. I do not care about Apricots. The Moorpark is the only good one that I have ever eaten, but the tree is much given to canker. A hint on Plums would be gratefully received. The best I know of are the Transparent Gage, the old Green Gage, and Jefferson's.

To my recently deceased friends Lord and Lady Rivers I am indebted for my residence here. It is a sweet homestead—a fair house, nice green field, nice orchard, two nice gardens surrounded by beautiful Hornbeam hedges, and a nice lawn with small fishpond, and twelve sloping beds for Roses in front of the drawing and dining-room windows. The house is in the Vale of Black Moor, the country beautiful, and the views

are magnificent; still I miss my old friends sadly, removed from me—or from whom I am removed.—W. F. RADCLIFFE, *Okeford Fitzpaine.*

THE PINE APPLE.

AND MR. THOMSON'S TREATISE ON ITS CULTIVATION.

(Concluded from page 341.)

AFTER some prefatory remarks on the introduction of the Pine Apple into this country the author at once proceeds to the subject of Pine-houses, and gives diagrams of those which he recommends. These differ little from the structures often met with. For summer use he recommends a span-roof running north and south, for winter a lean-to, and for suckers a common lean-to pit. Hot-water pipes beneath a bed of rubble are in all instances advised for giving bottom heat, and other pipes to warm the atmosphere. The only feature in construction which Mr. Thomson seems to insist upon is a somewhat steeper roof than is often given, in order to insure all drip being avoided. He prefers a number of small houses or pits to one or two large ones, as the proper culture of each section can then be more effectually carried out; some judicious suggestions are also made with respect to a steaming apparatus, or rather the mode of supplying moisture to the atmosphere. He by no means condemns the old and popular plan of growing Pines on a bed of fermenting leaves and tan; on the contrary, he appears to advocate it but for the trouble it gives. I may add that the pits at Archerfield, or at least a part of them, are so heated, and the fruit produced show that the plan suits them.

In the next chapter are given descriptions of some of the Pines most generally grown, with remarks on their merits. Those most approved of by the author are the Queen, Smooth-leaved Cayenne, and Black Jamaica; but other kinds are spoken of, as Hurst House Seedling, Bennett's Seedling, White Providence, and Charlotte Rothschild. Some other kinds, as the Black Prince, Enville, Antigua, &c., are named as being less recommendable.

Soil is the next subject treated on, and here there is something on which comment may be made. Mr. Thomson advises a soil containing a large amount of sand. What will our London friends say, who have so long been of opinion that Norwood loam was so excellent for this purpose? and what will some of our west-country friends say, who collect their Pine soil from upland moors and the precipitous rocks fringing the coast? while not a few think the compost cannot be too much enriched with sheep and deer-dung, and other substances having a tendency to make the soil retentive, and which are, therefore, the very reverse of sand in their effect, and yet good results follow in each case. The subject of soils, however, is by no means so fully understood as it ought to be, and perhaps the mode in which so many of us describe them may lead to an erroneous opinion. A soil containing a large percentage of sand is regarded as a light soil, and yet sand is about the heaviest substance bulk for bulk of any of the ingredients that constitute fertility. A bushel of pure sand is very heavy indeed; the term "lightness," perhaps, is applied to it in consequence of the small quantity of water which it will imbibe. On that account Mr. Thomson prefers it, or rather the class of soil which contains a large proportion of it, as being the most suitable for the Pine Apple; and the production of fruit of Smooth-leaved Cayennes upwards of 8 lbs. in weight, and of Queens weighing more than 5 lbs., with accommodation that was by no means the best for the purpose, gives his opinions a claim to respect, these weights not being solitary instances, but of frequent occurrence. Now, on soils less attention has hitherto been bestowed than on other points of Pine-Apple management, and great extremes exist in the kinds used. I have seen the best spit of a pasture field carefully selected for that purpose, while a friend of mine in the west of England, who grows very good fruit, obtains his soil in rough tufts (more than four-fifths herbage at the time), from the rocks. I am uncertain what is the nature of these rocks, and this, doubtless, is an important point; but they are either slate, granite, or limestone. I have also seen a mixture used in which chopped moss or sphagnum formed quite one-half the material. So many other points tend to modify the action of the soil in which the plant grows that it is difficult to give a decisive opinion on this matter, but I am inclined to think that Mr. Thomson's views are the best. The mode in which he uses it, and other particulars all invaluable to the grower of this fruit, are well explained.

The author next commences to detail his course of treating the plants, beginning with the sucker, and the modes which he adopts to obtain a quantity of them where an increased supply is needed. A plain and practical essay on their treatment follows, pots being advised even when they are intended to be afterwards planted out. The next stage arrived at is that of succession plants, and the treatment required by these renders a more lengthened narrative necessary in order to fully explain what is likely to be wanted of them in future, whether they are intended for summer or winter fruiting; and the propriety, nay almost necessity, of having separate compartments for them is pointed out, as well as the proper treatment to pursue in each case. A careful perusal of this chapter cannot be otherwise than useful to the young gardener whose experience in the cultivation of this fruit may not have been extensive, while there is much in it well worthy of the attention of those in everyday practice. The condition of the ball of the plant at the time of repotting, and what to do with it, are next dealt with, and the all-important subject of heat, both top and bottom, is fully discussed; then follow remarks on summer and winter management, occupying several pages, in which due attention is bestowed on watering and other points of management, and the reader now arrives at that important feature the treatment of the fruiting plants.

It is more especially at this stage that Mr. Thomson urges the necessity of having two or three compartments, so as to give the different sets of plants the treatment necessary to ensure their fruiting at the proper time; and by doing this Pines may be had all the year round. In most cases Mr. Thomson recommends a sort of period of rest prior to starting each set of plants into fruit, this period differing according to circumstances. The varieties most suitable for starting at different seasons are also stated, and the whole system of management lucidly explained, particularly as regards heat; and directions for the application and withholding of water are given in language that cannot be misunderstood.

Closely following the section just noticed is one on retarding the fruit, and keeping that which is ripe as long as possible—both matters well worthy of consideration, though not more so than that which is treated of in the next division of the work—viz., How to keep up a constant succession of ripe fruit all the year round. The author's observations on this subject are so good that I shall extract a short paragraph. After describing the proper time to secure suckers, he says, "In June and July I always endeavour to start a quantity of the true Smooth-leaved Cayenne. This is a noble Pine when well grown, being unsurpassed for appearance and long keeping after it is ripe, and swells better after October than any other Pine I know. The Black Jamaica is also a most useful Pine for winter swelling, and probably is unsurpassed for flavour at the duldest season of the year. The Queen is comparatively worthless as a winter Pine compared to these two; it does not swell kindly, and is always dry and juiceless compared to them."

Further remarks on the treatment of the sets of plants intended for the different periods are followed by a few notes on such plants as miss fruiting; and then the author gives a notice of the planting-out system, which, although he does not condemn it, he does not altogether approve of. He considers that the limited control which the manager has over the plants in this system is poorly compensated by the less amount of trouble which they give as compared with those in pots. This, doubtless, is true, and may account for there being, perhaps, fewer Pines grown on this principle now than there were ten years ago. At that time I believe those at Trentham were so grown, as well as those at the Royal Gardens, Frogmore, which the author quotes as a good example. However, the mode of management is given that those who may feel disposed to grow Pine Apples on the planting-out system may know how to proceed.

Perhaps the only exceptional portion of the work is that relating to the insects which sometimes attack the Pine—viz., the white and brown scale, and mealy bug. The writer acknowledges never having had to conquer these formidable opponents, and I certainly pity those who have. A remedy, though not Mr. Thomson's, is put forth on good authority, and is said effectually to destroy the white scale and mealy bug without disturbing the plants. I would certainly much prefer clean ones to those so treated; but if the remedy is effectual the discoverer is entitled to the thanks of Pine-growers. I may, however, remark that the destruction of the white scale is not an impossibility, for many years ago a case occurred in my practice which proved that this insect is unable to endure what the plant will do. At a place where Pines were not grown,

but where a mixed collection of plants was kept up, a young lady had three or four Pine suckers given her, and she wished them, for the sake of curiosity, to be kept amongst the flowering plants in a sort of half-stove half-greenhouse, in which were some creepers infested with white scale. I need hardly observe that the Pine suckers were speedily attacked, and the place not being at all suitable to their growth, it was determined to throw them away. This was in midwinter, and some hot dung being fermenting in a heap for forcing purposes, instead of throwing them away I buried one of the best of them in the hot dung, after removing the pot, soil, and a great portion of the roots. It remained there about twenty-four hours, was then slightly washed, potted, and placed in a frame heated by hot water and intended for Melons, which, in fact, occupied the rest of the compartment. The half-starved insect-covered plant speedily showed symptoms of doing better, and grew on rapidly, showing fruit and ripening in the same year one of about 4 lbs. weight, which was very good for a Queen. I mention this case as one that came under my own management, for, like Mr. Thomson, I have never had a collection of plants infested with this insect to deal with, and I confess that I should look with dismay on the appearance of a single scale insect on any one of those I might have in charge.

One further observation is proper to make on the work in question. Mr. Thomson thinks there must be a spurious variety of the Smooth-leaved Cayenne in cultivation as well as the true one, and in describing the kinds which he recommends I promised to allude to this. Having in my own practice always regarded the Queen and Black Jamaica as the all-important varieties, I cannot give any opinion on this subject; but I never saw the Smooth-leaved Cayenne in so good a condition as I did last year at Archerfield, Dalkeith, and one or two other places in Scotland. Mr. Thomson and his brother at Dalkeith grow it more extensively than they do Queens, and they estimate its weight when fully swelled to be about 1 lb. per pip—i.e., a fruit eight pips in height would, when ripe, weigh as many pounds. Queens were thought very good if they weighed half a pound per pip. The Smooth-leaved Cayenne, as grown by Mr. Thomson, of Archerfield, was certainly a very fine fruit, and the plant not by any means unwieldy. Three plants in pots, with fruit not quite ripe, were sent to the Edinburgh International Show last September, and were, perhaps, as much admired as anything there. The fruit would, I believe, average from 7 to 8 lbs. or more, the plants being dwarf and in pots by no means large. Queens were equally good, and I believe, one or more in Mr. Thomson's collection exceeded 5 lbs.

In drawing this review to a close I can heartily recommend the perusal of Mr. Thomson's little work to all practical gardeners. However successful they may have been in the particular branch of culture on which it treats, they will most likely find something fresh; while on the less experienced it has a double claim, as the practice of one of our best Pine-growers is clearly and ably laid down in all its details. If profane were wanting of the good quality of the fruit grown at Archerfield, I would only say that last September several English gardeners witnessed what was to be seen there. I remember meeting at that place a nobleman's gardener of high standing in one of the midland counties, and after looking at the Pines and inimitable flower-beds he cast his eyes around, and then on the ground, and inquired if there was not something peculiarly favourable both in the soil and climate to produce such results, or rather help to do so; yet few places would seem to be less favoured by its situation, which is on a plain of considerable extent, bordering on the German Ocean and Firth of Forth, the latter being only a mile off. That a combination of circumstances favoured in some degree the out-door department would appear certain, but there can be no question that from the truly artificial conditions under which the Pine Apples were placed, they might almost as well have been grown on the top of Ben Lomond as where they were, if managed with the same skill. That Mr. Thomson's Treatise may not meet the approbation of every one is very likely; but I for one would be anxious to see what criticisms are made upon it, and trust no one will be deterred from making such if they deem them necessary. My own views may be gleaned from the preceding observations, which, though directed to the work in question, were, nevertheless, based on a visit to Archerfield.—J. ROBSON.

NEW PLANTS AT MR. BULL'S.—In the account of these, at page 339, by a slip of the pen, *Schistocasia Portei* is placed

among the Orchids, instead of being included, as it ought to have been, among the Aroids.

TOBACCO—ITS CULTURE.

[We have so many readers in America and our colonies, and so many who are emigrating ask from us information relative to the culture of the staple crops of the countries whither they are proceeding, that we purpose occasionally publishing details which will supply the particulars they require.—Eps.]

There are some thirty species of *Nicotiana*, only two of which, *N. tabacum* and *N. rustica*, are much cultivated. Of these two, only one is generally grown—*N. tabacum*. Of this there are several varieties, each of which possesses qualities peculiar to itself, or qualities derived from the different soils, modes of cultivation, curing, &c. Each cultivator selects such variety as he thinks best adapted to his soil, climate, &c. The variety which will be noticed in the following is the Connecticut Seed Leaf. This, when properly grown on suitable soil, attains a larger and more perfect growth than any other known variety; the stem is erect and strong, attaining 7 feet in height or more; the leaves often grow to the length of 4 feet, and 2 feet in breadth. The flowers are trumpet-shaped, and of a rose colour. The seed balls or capsules are ovoid, from one-half to three-quarters of an inch in diameter, divided into cells compactly filled with minute seeds, which, when well ripened and properly saved, will retain their germinative properties ten years, as found by experience. This variety is the one grown for, and the most suitable for wrappers to fine cigars. It also combines the various qualities of hardiness, fineness of leaf, and quick maturity, so desirable in a climate like the northern and western States. Skillfully grown on properly enriched soil, it will yield 2,800 lbs. to the acre, in extreme cases 3,000 lbs.

SPED.—At topping-time let a desirable number of the earliest and best plants go without topping, keeping all the lower branches broken off. When the general crop is ripe, strip the leaves off and tie the stem to a stake. It is ripe when, without freezing, the capsules are quite brown; cut the seed with about 2 feet of the stalk, and hang it in a dry place, where it will not be disturbed. When wanted for use, select the best bolls, rub out the seed with the hands, and screen through a fine sieve.

SEED-BED.—A warm, sheltered situation, a deep, rich, sandy loam, free from weeds or seed, is the best. Plough or spade, in the fall, 10 or 12 inches deep; make level by harrow or rake, and cover closely with Tobacco stalks laid on straight. In spring, as soon as the ground will work well, remove the stalks and plough 3 or 4 inches deep, making a very narrow furrow-slice; and into each furrow, as turned, strew guano or hen manure quite freely; work in on the surface three pecks to a bushel of poudrette to the square rod, and make the soil as fine and the surface as smooth and level as possible. Use a table-spoonful of seed to each square rod of bed; mix it with sand, and sow broadcast very evenly; finish by rolling with a heavy roller. Make the beds 10 or 12 feet wide, that being a convenient width in working; cover with brush to keep fowls off, and to prevent radiation. To weed the bed, remove the brush, and stretch a plank across the bed, using blocks under the ends to prevent the middle from settling on to the plants when you sit on it to weed. The bed should be kept carefully clear of all weeds.

SOILS.—A sandy loam, neither very light nor heavy, is the best; the farther removed from this the poorer the quality of Tobacco. Ground which has been cultivated with some hood crop is the best, and produces the finest-grained leaf; such should be ploughed twice, the first time in April or early in May, the second about the 20th or 25th of May. It should be well done; ploughing deep and with narrow furrow-slices, and, between the first and second ploughing, using the harrow to keep down weeds, &c.

MANURES AND THEIR APPLICATION.—The main reliance is to be placed on farm or yard manure. Tobacco grows quickly, is a gross feeder, and needs large quantities of the best manure to feed on; from twenty to twenty-five cords per acre should be well fined, spread broadcast over the surface (after the second ploughing), and cultivated and harrowed to thoroughly incorporate it with the soil to the depth the cultivator runs; this, with the addition of the fertilisers hereafter mentioned, will, with such careful culture as here recommended, produce the best results. This application of manure should be made about a week previous to transplanting. Lay off your rows with a suitable marker, 3 feet 10 inches apart. Now with a coverer,

which hauls the soil into light ridges, follow the marker; this leaves a place for the row as smooth as a roller would leave the surface. Take a light wheel (or one may be attached to the coverer), and fasten blocks to the outer edge 2 feet apart, and have a shaft and handle for hand use. Go over the ridges with it, marking the place for hills; with the hand hoe open the holes and drop into them guano and plaster, mixed at the rate of 150 lbs. of the former to 250 of the latter to the acre; cover 2 inches deep with fine soil and spat with the hoe, leaving it a little depressed for setting the plant.

TRANSPLANTING.—A cloudy, moist time is the best; although by watering the ground, and again watering the plant after setting, it may be done with safety in very dry weather, if thoroughly done. The plants should be carefully raised from the bed, using care not to mutilate them or break off their roots; a dinner fork, to run down beside the plant, by prizing up will loosen them so that they may be raised by the leaves. Place them in a basket ready to drop out by a careful boy, one on a hill. Care should be used in setting to run the roots straight into the ground without doubling them, to the depth they grew in the bed; the plant when set should be left as nearly as it grew as possible, no pinching of the bud or crowding the leaves together. In pressing the soil down around them a little depression of the plants cannot well be avoided; this is advantageous rather than otherwise.

CULTIVATING.—In a few days the plants will have taken root; the cultivation should then be commenced with the horse cultivator, followed by the hand-hoe, stirring the soil but little close around the plants. The cultivation should be repeated once in ten days, till there is danger of injury to the plants in going among them with the horse and cultivator; then further culture should be done with the hoe, keeping the ground perfectly free of weeds. As the leaves are what the crop is grown for, they should be well cared for, in order that they may not be injured at any stage.

ENEMIES.—First is the cut worm, which eats off the plant; the only remedy is to hunt it out, kill it, and supply a new plant at the first opportunity; this worm will need to be looked after often, till all danger of injury from that cause is over. Next we have the green or Tobacco worm, which commences when the leaves are the size of your hand, sometimes. This worm comes from the egg of the Tobacco-miller—known in different parts as Hornblower, Humming bird miller, &c., a miller about the size of a humming bird, of a dusty brown, with orange-coloured spots on his body, a trunk-like tongue 5 or 6 inches long, and when not in use closely coiled between his feelers. The eggs are a trifle lighter in colour than the leaf, about the size of a pin's head. The worm is very small when first hatched, and very likely to escape unobserved; a small hole like a pin-hole in the leaf will reveal its retreat on looking at the under side of the leaf. The remedy is the same as in the former case, by destroying them and keeping the plants free from them, or they will have a ragged appearance.

TOPPING.—Here is where the best judgment of the grower is called into exercise; experience can only determine the right point, so that all the leaves will mature and none be wasted. After the plants have run up to flower, the tops should be broken off, leaving them uniformly 2½ feet high. All the plants will not be ready for topping at the same time, so some run a little past and others are topped sooner. All should be topped previous to August 20th.

SUCKERING.—This consists in breaking off the shoots which start from the stalk at the axils of the leaves; these should be kept broken off as fast as they make their appearance; the last suckering to be done immediately before cutting.

CURING-BARN.—A separate building, arranged expressly for the purpose, is the best; but stables and sheds can be used for want of better. A building 30 by 32, with 15 feet posts, will hang an acre of good Tobacco, by hanging three full tier and a part tier on the purlin beams. A basement room under a part or all of the building is convenient for stripping, packing, &c. One half of the siding should be hung on hinges, and there should be a ventilator in the roof to admit of free ventilation, &c. The cross beams should be arranged equally distant for resting the poles for hanging on. For poles get straight poles 5 or 6 inches in diameter, or sawed scantling 2 by 5; these are arranged 10 inches apart when filled with plants.

CUTTING AND HOURSING.—The Tobacco upon ripening assumes a thick, harsh, or brittle appearance, turns a spotted-green colour, &c. It should be cut before it become dead ripe, as it wastes less and cures more evenly. A good hay-knife or hacked saw is the best to cut with; the plant is cut close to the

ground by leaning it over a little and placing the knife under the leaves, and by an easy dab the stalk is severed from its roots and laid gently down to wilt; after wilting partly it is turned over to wilt on the other side, when it is ready to cart to the barn. A platform waggon is best to cart on; lay it on crossways, but uniformly one way. To save handling, two teams or waggons are necessary, with sufficient help to hand it from the load to the one who hangs. Commence by tying your twine to a plant, and place it by the side of the pole; on the opposite side, about 6 inches along, place the next, and secure it by a single turn of the twine from left to right, thus placing them alternately till the pole is filled, when the twine is secured. Good strong hemp twine is used. Cutting should be done when the dew is off; and all cut before noon, housed by that time, or it may sunburn. A clear, hot sun will burn it often in twenty minutes. The Tobacco all hung, give it all the ventilation possible in fair weather, without allowing the sun to shine on it directly; in rainy or foggy weather close it in. The sweat or pole burn happens in about two weeks after hanging if the weather be sultry and damp. Clear, drying weather or tight buildings are desirable at this time as a preventive.

STRIPPING.—When the sap is all dried out of the leaf-stem the Tobacco is cured; and when a mild, damp time comes open the barn that it may become moistened; when it can be handled without rustling take it down, carry it to the basement, and bulk it free from the ground, butts out, tips lapping about one-third. No more should be bulked than can be stripped out in three or four days, or it may be injured. It is sorted into two or three lots, according as it is more or less perfect; each sort is kept separate, and done up in hanks of about three to the pound; the butts of the leaves are kept even and bound neatly with a leaf wound round and tucked into the hank; neatness in this part often adds several cents per pound to the value. The Tobacco, after being stripped, should be bulked soon, to keep it from drying out.

CASING.—Most of our large, successful growers case their own Tobacco, after lying a short time in bulk; a mild time is chosen, when it is pressed into boxes 2 feet 4 inches square, by 2½ feet long inside measure; 375 lbs. are pressed in each case, with a lever or screw for the purpose. The hanks are laid in butts to the end of the box, away one inch, to prevent crowding against the end; the leaves are straightened out smooth, to keep them from pressing in wrinkles. The following season the Tobacco undergoes a fermentation or sweat, which makes it Tobacco ready for manufacturing.

By high manuring and thorough culture, Tobacco may be continuously grown on the same ground; but it is generally at the expense of the fertility of the rest of the farm. A better way is to make it one in a course of rotation; in this way an improvement in the fertility of the farm is constantly going on.—(W. H. WURR, in *Albany Country Gentleman*.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CYMBIDIUM HOOKERIANUM (Dr. Hooker's Cymbidium).—*Nat. ord.*, Orchidaceæ. *Lin.*, Gynandria Monandria. Native of the Sikkim Himalaya. Flowers large, green; lip yellow, spotted with reddish purple.—(*Bot. Mag.*, t. 5574.)

THIBAUDIA CORONARIA (Small-leaved Thibaudia).—*Nat. ord.*, Vacciniaceæ. *Lin.*, Decandria Monogynia. Native of the Andes. Flowers dull red.—(*Ibid.*, t. 5575.)

MICROCACRYS TRIRAGONA (Strawberry-limbed Cypress).—*Nat. ord.*, Conifereæ. *Lin.*, Dicoela Monandria. Native of Tasmanian Mountains. Cone fleshy, and brilliant red.—(*Ibid.*, t. 5576.)

IRIS RETICULATA (Netted Iris).—*Nat. ord.*, Iridaceæ. *Lin.*, Triandria Trigynia. Native of Georgia, Persia, &c. Flowers rich purple, and richly perfumed like the *Vicia*.—(*Ibid.*, t. 5577.)

CEROPEGIA SORORIA (Kaffrarian Ceropogia).—*Nat. ord.*, Clethraceæ. *Lin.*, Pentandria Monogynia. Native of Kaffria. Petals reflexed like the Cyclamen's, and streaked with purple. *Sororia* (sisterly) is one of the most beautiful names occasionally bestowed. It was given, because the plant is due to Dr. Harvey by a lady who had received it from her mother's species, *C. Bowleri*.—(*Ibid.*, t. 5578.)

TACSONIA VAN VOLXEMI.—See p. 329.—(*Hort. Bot.*, t. 389.)
ROSE—*Black Prince*.—Flowers dark, single, and of a fine

beautifully blended. Introduced by Mr. W. Paul, Waltham Cross Nursery.—(*Ibid.*, pl. 290.)

RHODODENDRON DENISONII.—Flowers white, tinged and dotted at the base with lemon colour. Introduced by Mr. B. S. Williams, Nurseries, Holloway, who states it to be the progeny of *R. Dalhousianum* crossed with *R. Edgeworthii*.—(*Ibid.*, pl. 291.)

HYACINTH—Sir Henry Havelock.—Lobes of the corolla intense purple, edged with mauve. The colours blending give quite a new tint.—(*Ibid.*, pl. 292.)

PEAR—Van Mons Léon Leclerc.—"This excellent Pear was raised by M. Léon Leclerc, at Laval, in the department of Mayenne, France. It is not known exactly what was its parent, for M. Leclerc had sown seeds of St. Germain, Glou Morecau, and Easter Benré; but judging from the appearances we should be inclined to suppose that it has taken its origin from the St. Germain. The tree first produced fruit in 1828; and in October, 1837, M. Leclerc sent specimens of the fruit through M. Vilmorin to a meeting of the Paris Horticultural Society with the following note:—

"M. Van Mons has not only handsomely accepted the dedication of this Pear in declaring to me that he regards it in all respects of the first rank, but also, by a refinement of *politesse*, he has exacted that the name of the raiser who paid him this compliment should be placed in continuation with his own, for the sake of distinction. This is, then, the Pear Van Mons Léon Leclerc. This explanation was necessary to justify such a designation."

"The fruit is of the largest size of Dessert Pears, and is of an oblong shape, uneven and undulating in its outline. The skin is a pale dull yellow colour, covered with russet dots and traces of russet. Eye open, with spreading segments, set in a very shallow basin. Stalk from 1 to 1½ inch long, set on the end of the fruit with a slight depression, or obliquely without any depression. Flesh yellowish white, buttery and melting, very juicy, sugary, rich, and deliciously flavoured.

"A Dessert Pear of first-rate excellence, which ought to be grown in every collection. It ripens in the end of October and during November."—(*Florist and Pomologist*, v. 89.)

GLAZED AND FLUED WALL.

HAVING seen in "our Journal" some statements by your correspondent "BETA" adverse to protection for wall-fruit-tree blossoms, I have been induced to send you the following description of how I have seen Peach and Apricot blossoms protected at Haggerstone Castle, Northumberland, and the trees successfully fruited about 330 miles north of London.

Fig. 1 is an end section of a Peach wall 290 feet long, which had, some years ago, been artificially heated at no little expense and trouble by keeping sixteen furnaces going, but they have been left unheated for years. *a a* Are smoke flues; *b* is a board 1 foot broad, to which the canvas or hexagon netting is fixed; *d* one of a line of pegs to which the netting, by means of rollers attached, is lightly secured at about 18 inches from the ground.

Fig. 1.

In fig. 2 *a* is an iron stay projecting from the coping of the wall, on which the moveable board, *c*, is fixed by means of iron bolts at *b*. At *d* there is a narrow piece of wood fixed about half an inch from the front of the board; on the face of this the canvas, *e*, is nailed. The water is thus thrown a little over the canvas, which carries it safely to the bottom.

Fig. 2.

The netting is made in lengths of about 10 or 12 feet, and each side is furnished with a number of brass rings, and by running a cord alternately through these

rings they are tightly laced together. Thus fixed, they are perfectly secure from wind, and with some slight exception, perhaps, at the joinings, the covering is waterproof. The openings at the bottom and joinings, and the innumerable meshes of the netting, give abundance of ventilation. There is plenty of room below the net to permit of the cultivator pursuing his operations without its removal. The Peach trees on this wall are supported by means of iron eyes fixed along the lines of bricks quincunx fashion, and pegs made of the young growths of the Privet. This, I think, is a great advantage over nailing, as it does not break up and disfigure the wall, and affords but very little harbour for insects.

The Apricot wall is protected in the same way as that on which the Peach trees are trained, and last year the fruit set very well, but dropped off by the hundred in the stoning process, owing, I have no doubt, to the roots having penetrated so far below the drainage of the border as to come in contact with water stagnant and cold as in winter. Owing to the extremely low and level character of the situation of these walls, it is quite impossible to have drainage perfect; but, notwithstanding, fair crops of fruit are generally taken from these walls.

The canvass is put on when the buds begin to show colour, and is not removed till the fruit is swelling and all danger of frost past. Protection in this locality is not only beneficial, but absolutely necessary for the security of the crop. The spring months are generally cold, with some boisterous, cold, cutting winds from the west directly off the Cheviot Hills, the tops of which are often covered with snow well into the spring months.

This mode of protection offers some advantage to people living in localities where it is desirable to have the trees as much forward as possible with safety, so as to give them all the advantage of the summer months for maturing young wood and fruit buds for another season. I am convinced that with such protection, and shallow sloping borders perfectly drained, and protected from frost and excessive wet during the winter by means of wooden shutters, Peaches might be grown with success further north than they are.

"BETA" seems to attribute the cause of his failure to the protection, when he says "I will protect no more," but I think the extreme wetness of the season is sufficient to account for any failure in fruit not setting. Our trees here (in Kent), were merely protected with Laurel branches, &c. Peaches have set very well. Apricots have not done so well, but they are not at all to be called a failure.—Bon.

A PEEP AT THE WOODS IN ODD PLACES.—No. 1.

WHITE CEDAR, BLACK ASH, AND BASSWOOD.

"What a splendid pile of fencing you have there, William!" I exclaimed to a friend as we stood on the edge of a clearing, looking at a large pile of beautiful, clean, straight Cedar cut down and trimmed, ready for being converted into rails, or, to use my friend William's expression, "hauled and ready for splitting." Before, however, we split and use up these individual trees, come with me (in imagination), and let us have a look at the beautiful Cedar tree in its own habitat; and though we cannot expect to make its acquaintance with dry feet, still I feel convinced that the beautiful object itself, with the delicate perfume it sheds around, will amply repay us for all the trouble we shall be obliged to take to obtain a sight of it.

The clearing, on the edge of which I have mentioned that we were standing, occupied one side of a hill, on the crest of which we were stationed. Looking behind us we saw a piece of brown, cold, untidy-looking land covered with a litter of leaves, small twigs, and chips, with the marks of more than one huge fire; and at every few yards, or feet, as the case might be, a forlorn stump, standing some 2 or 2½ feet out of the ground. This was the clearing, and to help to fence it off the Cedar trees had been chopped (*Anglicè*, felled), and hauled or brought out of the bush to one spot. Looking before us who can describe the beauty of the glimpses, caught between the trunks of some noble timber trees, of a lovely woodland view, in one direction contracted to the distance of a few hundred yards by the richly wood-clothed hill opposite us, and in another stretching away for miles, displaying a glorious prospect of alternating hill and valley, curiously diversified and ornamented by patches of corn, Potatoes, or some other crop, appearing like small islands planted in a lovely green sea of native forest and bush? Between us and the opposing hill

runs the lively, brilliant, and clear river Credit, rapidly, and at times noisily, hastening its way to Port Credit, on Lake Ontario, where its crystalline waters are lost in the waves of that noble, inland, fresh-water sea. Oh, beautiful river! many a musing hour have I spent sitting on the semi-prostrate trunk of some mighty monarch of the forest, which in his palmy days had stood on your bank, and with his huge limbs softened the blustering wind lest it should too roughly ripple the smooth surface of your glassy waters; and now in his hour of age, when his roots can no longer give him support, and the rude wind has conquered and overthrown him, he leans lovingly o'er your stream, and though decaying seems striving to proteet you still. Here have I sat and watched the mingling tints of the foliage of the Cedar and Hemlock, the Elm, the Ash, and the Bass-tree, the tall straight Hickory, and the lofty Pine. Twining amidst these, and adding greatly to the general wildness, luxuriance, and loveliness of the sylvan banks of the river, the elegant Vine casts its graceful arms, embracing and linking together the limbs of various trees, and converting the whole into a closely woven arbour, affording cool and grateful shade during the burning hours of the noon of this climate. But, alas! the truth must be told: this shade harbours swarms upon swarms of those fearful and ferocious creatures of prey and torture vulgarly called mosquitoes, whose venomous stings are more to be dreaded than the surly bear or howling wolf.

And now being on the bank of the river, let us proceed along it, in spite of the mosquitoes, till we reach that low swampy piece of ground which we see in the next bend of the river below us, where the foliage looks so dark and green, though enlivened with the lighter hue of a Birch tree and the curious soft-looking branches of the Hemlock. This is a Cedar swamp; and here, in the fall of the year, and when harvesting work is ended, we shall find the settler, with what help he can raise, hard at work chopping—i. e., felling Cedars for posts and rails. The White Cedar (*Cupressus thyoides*), grows, when not too crowded, as a beautiful cone of darkish-green foliage, the apex of which is of a much lighter green in consequence of the young shoots. It is an evergreen, and varies in height from 20 to 60, 70, and even in very favourable circumstances to 80 feet or more, though this last height is comparatively rare. The lower boughs droop most elegantly towards the ground in graceful sweeping curves, and the whole tree is an object of great beauty, most pleasing to the eye, and on account of its delicious and delicate perfume equally so to the olfactory organs. The tree grows sometimes with a straight grain—i. e., perpendicularly, but more generally spirally. This can at once be detected on looking at the bark, and the straight-grained trees are chosen as more readily split into rails and laid together for that purpose, whilst those of spiral growth are better for posts, and, consequently, where required, reserved for that use. One would imagine, to look at a standing tree, that it would be almost impossible to split any trunk so full of branches; but such, with this tree, is not the case, for it splits, especially such logs as are of straight grain, cleanly and readily, and any one accustomed to the use of the axe and tolerably skilful, can without the aid of wedges split a log of from 6 to 12 inches in diameter, and from 12 to 15 feet long, though, of course, where the grain is spiral there is more difficulty, and wedges would be required for logs not exceeding a foot in diameter. The bark is rather rough externally, of a pale brown colour, and burns quickly, and with a very pleasant perfume. The wood is light and soft, though very durable, long resisting the attacks of the weather, being but very slightly affected by changes of damp and dryness, and is, therefore, invaluable as fencing, especially where the fences are made, as they mostly are in Canada, by merely laying the rails one upon another in a zigzag manner, so that they overlap each other, the lowest rail resting on the ground.

The next most valuable wood for this purpose is very much heavier, denser, and closer-grained, and grows on higher ground than the Cedar; it is called Black Ash (*Fraxinus sambucifolia*). The White Ash (*F. americana*), I will only mention as being very similar, in fact, almost entirely like our own English Ash, and the timber is valuable for similar purposes to those for which we use it at home—viz., cart and coach building, &c., possessing great strength and elasticity. The Black Ash is different, its main value being for fencing purposes, since in other respects it is inferior to the White, being a smaller tree and the timber of greater specific gravity, and with less elasticity and toughness. The foliage is of a dark green and has a sombre appearance, the bark and wood being also of a deeper and duller hue than those of the White Ash.

What a lovely collection of plants is this at the foot of this Black Ash, under the boughs of which I am now standing on the hill side, looking between the trunks of the grand sylvan monarchs surrounding me, at the pure crystal streamlet running from a pretty little spring, which wells up close by and hurries with noisy chattering impatience to join in the dance and whirling race of the river which rolls at the base of the hill. Growing on the bank just over the spring, in a soil composed of decayed leaves, bits of broken twigs, and dead moss, on the top of a stiff clay, we see a beautiful dark green shining-leaved little plant, and stoop to pluck it, but the stem seems tough and not easily broken, and in pulling it away we bring with the leaf a long bright yellow fibre, and on turning up the leafy mould with our hands we are astonished to find a perfect nest of these little yellow fibres. This plant is the Golden Thread (*Coptis trifolia*), and we find it taking a place in the pharmacopoeia of the United States as an astringent, though from my own experience one of very slight value, but still of great repute amongst settlers and backwoodsmen. What is this running away in long creeping shoots, and sending up every here and there, at irregular intervals, most elegant miniature Fir trees with one long top shaped very similarly to a fox-brush, the whole plant being of a beautiful bright green except the top, which shades off gradually to a greenish yellow, and standing from 6 inches to a foot in height? It is a Club Moss, and is, like the Golden Thread, a plant said to possess medicinal qualities, being used in ointments, &c. Now, let us move a little further up the stream, though before we go we will just pluck this pretty, spreading, five-armed plant with its delicate black stem and horizontal fronds; it is one of Florida's fairest productions, and is one of the Maiden-hair Ferns.

As we proceed up the river we come to what in this part of the world is termed a "jam"—that is, the river is blocked up and rendered impassable to any boat or other floating thing, and it occurs in the following manner:—Some tree or log—that is, trunk of a tree cleaned up and ready for use, in floating down the river grounds in a shallow place and sticks fast, generally at one end, whilst the other end swings round and rests against the bank, thus narrowing the river's channel; again, another log comes and may go through and pass on its journey downwards, but most probably is caught by the log already fixed; others, again, come down the stream until another ground or is eanted across the gap between the end of one fixed log and another, or a fixed log and the opposite bank; in this manner the dam across the river is complete, and small bushes, limbs of trees, logs, and trees themselves, are all stopped and woven together in an inextricable mass, which not even the floods of spring, caused by the breaking up of the ice and melting of the snow, can always remove, since on one or two of these jams I found most perfect little gardens, and on one in particular I saw growing, one species of Fern, five kinds of Grasses, the Blue Flag or Iris, the wild Clematis or Old Man's Beard, and the Hop. Under this garden the clear river flowed at the rate of four miles an hour, its soft murmuring ripple and the cool shade of the lofty trees growing on its edges, combining with the marked silence of the woods at mid-day to strike the mind and impress upon the senses that luxurious and delicious feeling of sweet and calm repose, expressed in the Italian words *dolce far niente*.

As, however, that decidedly enervating feeling is hardly compatible with forcing our way along the banks of that part of the river where I now wish to lead you, let us throw it aside, and pushing over the jam follow me into this low piece of ground lying between the margin of the river and a lofty bank some 300 or 400 yards off, and comprising an area of about two acres. Through this, and amidst a dense thicket, run various little gullies, each the bed of a clear streamlet, the whole neither more nor less than a network of small branches running off in various directions from the bed of the river, which is here in no part deeper than 4 feet. Well, we will hop over these little brooks and thrust our way through the bushes, for those who love Black Currants will be amply rewarded with as many as they choose to eat, and all for the trouble of picking, since the greater portion of this plot of land is so closely overgrown with this shrub as to render it a difficult matter to make a passage through the bushes. The fruit, though of small size, is sweet and of good flavour, but still being wild is quite neglected by the inhabitants, for nobody seems to think it worth gathering or preserving. This, however, is not the case with the Raspberry, which grows wild all along the dry banks of the river, in dense thickets; for its fruit is gathered and used in various ways, making a delicious preserve, though requiring more sugar

to enable them to keep than is needed in boiling down the similar fruit of our gardens. By the side of the Black Currant bushes we find two kinds of Elder, a white and a black sort, both bearing enormous bunches of beautiful deep purple, almost black berries, though those of the black Elder are alone used, as there is a prejudice against the white one, the berries of which are considered poisonous; for my own part, however, I could not discover the poison, for being very fond of Elder-berries I ate handful after handful of them without the slightest inconvenience. I may here mention, that I noticed amongst the Raspberry thickets a larger number of humming birds than anywhere else.

Now, kind reader, I have brought you to a pretty little clearing on the margin of the river which here divides to embrace a lovely islet covered with Alder bushes, which are in turn covered with Vines bearing small sour bunches of black Grapes. In the centre of the clearing, which is about 15 yards wide by 20 long, stands a lovely specimen of the Bass tree (*Tilia americana*), tall, straight in its trunk, and with a handsome spreading head, amongst the boughs of which, twining round and supported by them, we see the elegant wreaths of the Virginian Creeper, whose leaves are just beginning to take their autumnal tints of bright yellow and vivid scarlet. The Bass is a species of Linden or Lime tree, growing exactly like it, and only distinguished from it by the size of its leaves. The bark of the tree is highly useful, being employed by the Indians for ropes, and for making baskets, and the inner bark is used to make the well-known bast mats of the gardener; whilst the wood, which is white, soft, and easily worked, is of the greatest use to the coach-builder for panneling, being capable of taking an excellent ground for painting and varnishing, as it is not apt to warp or shrink.

At the foot of the particular tree I here mention, I once spent a very merry afternoon. Some young men with whom I was acquainted, proposed a sort of picnic in this little clearing, and we were all to bring such articles as we could obtain towards a *diner à la campagne*, and meet here to cook and dispose of our various supplies. When the hour arrived at which we had appointed to meet, I was the first upon the ground, but was speedily joined by the others, all variously burdened. For my part I bore a supply of drinkables, in the shape of whisky, also a loaf of bread, some tobacco, and pipes; next came a friend with a quantity of Potatoes; another brought pepper, salt, and beer, and pockets filled with Apples; and now appear two together, bearing with them a goose, and a sucking pig; another brought two chickens; and again another some very fine fresh-caught trout—in fact, all brought something, none came quite empty-handed, and rare fun and boisterous laughter proclaimed each fresh arrival. But, lo! what a mistake, although three or four thirsty individuals had remembered to bring cups, not one in the whole party had thought of table knives, forks, spoons, or plates! Well, well! we are in the lurch, and at least four miles from the nearest log hut, so we must do the best we can, for it will not do to lose our feed for such trifles as these: so, no man being without a heavy knife of some sort, all set to work, one party as plate manufacturers, this article being formed of a square piece of Bass bark cut round with the knife and then pulled off the tree, and another party as cooks. The cooking was done in the following manner, and to any one loving tender, well-cooked meat in which all the gravy is preserved, I can safely recommend this process of cooking. The goose, pig, and fowls were brought just as they were to the margin of the river, and there well rolled in the mud; this mud, with the aid of some clay, was made into a thick paste, and the birds and animal were entirely enveloped in a thick coating of this, and then placed in a good hot fire, and thoroughly baked, after which they were taken out and eaten, and I must say most excellently cooked they were, and most perfectly did we enjoy our picnic, and each other's company, till late in the evening, when by the light of a beautiful moon we all rose, and in company wended our way to the village.—A SURGEON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

By continual surface-stirring weeds will never make their appearance amongst growing crops; but there are some parts of the garden, such as those quarters devoted to Gooseberries, Currants, Raspberries, &c., which, not requiring continual surface-stirring, are apt to be neglected. The hoe should be kept constantly at work amongst these, whenever the sun is power-

ful enough to wither the weeds as they are cut up. *Beet*, the first sown to be thinned-out, and if there are any vacancies the thinnings may be successfully transplanted if they are carefully lifted, a long dibble used, and the root placed perfectly straight into the hole. With such favourable weather as we have had, there ought now to be a good breadth of *Cauliflowers* and *Cabbages*; keep the earth well moved amongst them. Cauliflowers in a forward state must be supplied with liquid manure, even if the ground is wet. *Celery*, a few trenches should now be made ready for the earliest crop. On soil with a wet bottom the trenches should not be made too deep, so that the plants may be nearly on a level with the surface of the ground. A dry bottom with deeper soil may have deeper trenches. In either case give the rows a good width, because the Celery should never be earthed-up until it has nearly attained a size fit for use, and, therefore, the intervening spaces may be cropped with Lettuces, early dwarf Cabbages, and Cauliflowers, all of which would come off before the final earthing. *Carrots*, where young ones are in request another sowing may be made; and advancing crops of the same must be kept well surface-stirred, and thinned-out to from 4 to 6 inches apart, as very large Carrots are seldom required. The ridge for *Cucumbers*, recommended last week, will now be in a proper state to receive the plants; let them be put in without delay, and shade the glasses for a few days. At the same time a few glasses may be sown with seeds of the Vegetable Marrow, and Cucumbers for succession, and for Gherkins. For the latter purpose, on warm soils seeds sown in the open border will suffice; but on colder soils it is better to forward the plants in pots, and have a sloping bank thrown up facing the south. Plant them near the top, and train the vines downwards, stopping them occasionally. Stop the early *Peas* as soon as the first blooms are well set. *Parsnips* require to be thinned to 9 inches or more apart if the ground is rich. Plant-out *Tomatoes* in light compost under a south wall, also *Chilis*, *Capsicums*, and *Basil*; in doing which, if they are at all pot-bound, let the roots be gently loosened and spread out.

FRUIT GARDEN.

During the process of nailing-in the shoots of Peaches, Nectarines, and Apricots, examine if there are any nails so placed as to be likely to injure the swelling fruit, and remove them. In nailing in young shoots use strong cloth shreds of good texture, cut to a sufficient length to allow of plenty of room for the wood to swell. Sometimes short shreds are used, and bound so closely round the wood that at the pruning season shoots are found to have an indented ring, and very often a large piece of gum. Vines will now require constant attention in stopping and nailing-in. It will also be necessary to go over Pear, Plum, and Cherry trees to remove gross shoots, and to stop those not wanted for laying-in. This repeated as may be necessary during summer is preferable to the old practice of allowing the shoots to remain upon the trees until midsummer, and then cutting them back to two or three eyes. Do not forget to use every available means to keep Strawberries in a free-growing state by timely applications of water, and frequent surface-stirring.

FLOWER GARDEN.

Except in favoured localities it will be unsafe to commence planting out the bedding stock until we experience a decided change of weather. In the meantime let the plants be nicely hardened off and arranged, so that when planting-out is commenced it can be done expeditiously. Also decide what is to occupy each bed, and have everything in readiness. Push forward late-propagated stock, and endeavour to keep the whole healthy and growing slowly. Some allowance must be made in regard to the time when it is desired to have the principal display of flowers. If early, the plants will require planting more thickly, and need not be stopped; and if not before a later period in the summer, somewhat thinner; and the flower-buds should be pinched off as they appear till the plants have filled the beds. When a large quantity of hardy shrubs is annually forced, either to decorate the conservatory or drawing-room, it is not desirable to pot a fresh stock each season, as a number of the deciduous shrubs, as *Roses*, *Lilacs*, *Thorns*, *Honeysuckles*, &c., may by proper treatment be made to bloom for several successive seasons. Select, therefore, the most suitable plants when removed from the houses, and give them some kind of temporary shelter to gradually harden their foliage. These cramped for pot-room shift into pots a size larger, using rich turfy loam, and plunge them in an open situation, that the wood may ripen early. These plants, from having been previously forced, will bloom earlier than the new stock.

of which a portion should each year be potted to replace such as become useless for further work.

GREENHOUSE AND CONSERVATORY.

Camellias making their wood should have constant shading, the house to be kept very moist day and night, and the plants frequently syringed. Pay every attention at this period to plants of climbing habit, whether festooned from the roof, up pillars, or on trellises in pots. Let stopping, thinning, training, &c., be attended to as required. Many of these plants are unproductive of blossom for want of stopping the gross shoots. Weed out the inferior specimens and kinds in the greenhouse, so as to give plenty of room to the best, and never allow the plants to touch each other during the time they are making their growth. All plants which are becoming shabby must have the old blooms removed immediately, and, if necessary, be cut back and started into fresh growth. Look well to watering, but avoid saturation, and give abundance of air at all times, unless you like to syringe, and shut up for an hour or two before 4 p.m. Many plants, such as Diosmas, Myrtles, and other things which have done blooming, if cut back and repotted will, with attention, make fine plants by the autumn. These old plants and many more are very valuable in large establishments, where many cut flowers are required for drawing-room decoration.

STOVE.

As regards the plants in this structure, thorough cleanliness, free ventilation, plenty of atmospheric moisture, and slight shading in bright sunshine, are at present the chief requisites. No means should be neglected to encourage a free growth at this period in Orchids, in order to have their pseudo-bulbs firm, well fed, and ripened betimes. Take care to secure cuttings of such plants as Brugmansias, Clerodendrons, Erythrinas, Poinsettias, Eranthemums, and of those useful winter-flowering plants Euphorbia jacquiniæflora and Gesnera bulbosa. Continue to attend to the points of cultivation previously recommended, remembering that now is the period of rapid growth, and for supplying all the encouragements necessary thereto.

PITS AND FRAMES.

These structures will almost be done with for this spring's planting. Cuttings of dwarf Phloxes, Alyssum saxatile, Arabis, &c., must now be put in.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Prepared for trenching-down some of the winter vegetables, as Cabbages, Brussels Sprouts, some being yet good, and Scotch Cabbaging Kale, very fair as respects the young sprouts. Planted out more Peas. Some of our friends talk of thinning the rows before staking. Sowing before staking is with us of no use, and equally so with staking if the pheasants can reach through the stakes. Securely staking at once, even if that were effectual, takes more time than we can spare just now, and, therefore, we have sown a lot more under protection in semicircular drain-tiles and boxes. Those transplanted when about 3 inches in height, and staked at once, are doing well, and neither pheasants nor any other enemies have interfered with them, though hen Pheasants have such a love for us as to be sitting on a dozen of eggs close to these Peas. We have a lot of Scarlet Runners in boxes coming on well, but we sowed several rows in nice mellow soil and staked them at once, putting lushy twigs so thickly at the bottom on each side that it would be no easy matter to get at them. However, staking takes up rather too much time just now. We have also sowed Dwarf Kidney Beans for succession, and lest the seeds should be meddled with, we have a lot in boxes just coming up that will replace them, or come in before them. The gardener will pretty well be a match for any intruding enemy in the long run, but it is the time and extra labour that tell, and throw his arrangements out of joint.

Pricked out lots of Celery plants in fine soil, with a bottoming of rough rotten dung and soil, so as to have balls about the roots at planting time. Planted out Lettuces: sowed more. We like to sow thinly in rows, and not to plant much after this time. Put herb-beds in order; especially planted a bed of Spearmint, and put the tops under a hand-light to strike more plants. Spearmint is with us a shy crop, requiring renewing every year. To suit our purpose the herbs are in a corner rather moist for them, and nothing suffers more than the above Mint. We can only keep it on by fresh planting. Peppermint, on the contrary, seems to look after itself, and not seldom we

have taken the shoots of the latter for the former without any one being the wiser. Made, also, fresh beds of Sage, merely inserting slips some 8 inches long well into the ground. They will be nice plants before the head stuffing-time comes. Divided some roots of Tarragon, and will most likely fit a hand-light in a shady place with cuttings, as some people think a salad poor without a few leaves or sheets of this herb, and a few sprigs of Chervil. Sorrel also requires dividing, which must be done, as a dish of Sorrel depends for receiving approbation, even from those who like it, very much upon being grown in fresh, well-enriched soil. When all such things, and soup herbs in general, are kept in one place, it often saves many a journey and much time. To save both we generally have a little Parsley, Spinach, &c., in the same place, along with Thyme, Pennyroyal, Marjoram, &c.

Looked after Cucumbers. Set those intended for Gherkins and ridges, also Vegetable Marrows, in a frame in the meantime, to grow on until we can find room for them. Threw wood ashes and soot over vegetable seeds, and watered Cauliflowers to hasten them on, as from having our earliest destroyed by rats and mice we shall not be so early as usual. Fortunately good white Broccoli will last some time yet. Sowed the main crop of Parsley, and will sow again under protection in the end of June, and that makes us pretty well independent of the winter. See previous weeks for general details.

FRUIT GARDEN.

Run the hoe through the Strawberry quarters and borders to destroy all incipient weeds, and to give an opportunity for the rains to descend. Will take young plants from a border for the last forcing. Disbudded trees, thinned shoots, and stopped shoots in the Peach-house and orchard-house; further thinned shoots in the Fig-house; regulated the shoots and bunches in vineries—the early Vines, Sweetwaters, in a narrow pit, started at Christmas, came in in the end of April, but the glass was covered with straw covers every night. We have thinned all Grapes that need it, except a few Muscats, and they can wait a few days, as though thick enough they seldom set so very thickly as to injure one another early. Watered fully half of the borders of the orchard-house with manure water. Watered the inside borders of the vineries with drainings from the dunghill, after throwing some soot carefully over the surface. The ammonia from the soot will do good for some time, even as it escapes into the atmosphere of the house. The earlier vinery-borders outside are still covered with litter, and advantage has been taken of the little heat given off to make a temporary bed, with a rail back and front, and old sashes laid on, whilst beneath them are placed Scarlet Geraniums, that need a little strength for beds. The late vinery-border is exposed, only covered with a layer of horse-droppings, and on these, as the showers were coming, we put a sprinkling of soot, for the rains to wash down. These Vines having borne prodigiously for many years, we shall give the borders a sprinkling of guano or superphosphate. We like the latter best, because it is so safe in inexperienced hands.

Gave a good watering to the border of the Peach-house, where the fruit is swelling fast. A little red spider appeared at one corner, and we have had the leaves carefully washed with a brush and sponge. At that place the pipes come almost close to the wood and the fruit, the best of all arrangements for red spider. Here we have placed bricks set in sand on the flat pipe, and poured sulphur on and between the bricks, and also some all along the pipe. We are anxious about this spot, about half a yard, as we know how quickly this enemy spreads, and that prevention is better than cure. With the exception of two or three Strawberry plants, this is the only case as yet in which the enemy has appeared this season. There has been a little sulphur on the pipe almost constantly, at least sulphur mixed with water and a little soot to colour it, for when of a lightish colour from sulphur water alone, or from sulphur and a little lime in exposed places, so as not to be removed easily, the pipes do not throw off so much heat as when they are darker in colour. The first wet day we shall daub sulphur, made into a paint with strong softsoap water, in open places on the back walls of houses where the sun has the chance of striking with full force. Such spots will give off sulphur fumes for a long time. Stopped and regulated Melons for fruiting, being later than usual.

ORNAMENTAL DEPARTMENT.

Out of doors chiefly rolling and mowing the lawn; weeding and rolling walks; digging beds; protecting and exposing bedding plants according to the weather, letting them have all the

nice mild showers, and protecting them from the changes of the night; potting and assisting the latest, and giving a warm syringing to the cuttings of Verbenas, &c., inserted in a bed in a frame as lately detailed, which promise to be all right in a fortnight's time; fresh arranging houses; potting Fuchsias, Geraniums, &c. Some good plants of Rollisson's Unique Geraniums had a few green fly on them; they were placed in a smoking-box and smoked, and kept there for several days, and then were cleaned and well syringed. A box, or a little close closet or room, is very useful for this purpose, as a pinch of tobacco will be as effectual as a pound or half a pound in a larger place, and tobacco is no trifle in some places where large houses are smoked, and then the disagreeable odour of the fumes lingers for days afterwards. Potted many plants, and gave more heat-room, and a little bottom heat to Caladiums in a pit; shifted those in smaller pots, and started Gesnera zebra and its varieties for autumn display. Potted Balsams and Cockscombs, sowed more; and pricked out Stocks, China Asters, and other annuals, &c.—R. F.

COVENT GARDEN MARKET.—MAY 12.

A GOOD supply of out-door produce is now coming in, and that from under glass is also improving, although far from what we usually have at this season. Strawberries especially being very short. A few Peaches, Nectarines, Melons, and Figs of good quality are to hand this week.

TRADE CATALOGUES RECEIVED.

W. Hooper, New Wandsworth.—*Descriptive Catalogue of Plants.*
James Backhouse & Son, York.—*Catalogue of Store, Greenhouse, and Bedding Plants, Ferns, Orchids, &c. Supplement to Catalogue of Alpine Plants.*

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*
N.B.—Many questions must remain unanswered until next week.

CEDEAR OF GOA (C. B. F.).—The Cedar of Goa will not stand frost. It requires protection in winter near London.

STRAWBERRY STEALKS GRUB-EATEN (A. Amateur).—The stalks of the leaves and flower-trusses are eaten through by a grub, called by gardeners the "Leather Jacket." It is the larva of the daddy-long-legs. Scratch away the earth with a knife from around each plant, and destroy the grubs you find.

BOOKS (A Young Beginner).—They treat on two different branches of gardening. The Dictionary enumerates the species of plants and their culture. "The Science and Practice of Gardening" explains all the operations of horticulture. You should have both the volumes. (W. R.).—The third edition of "Hogg's Fruit Manual" is now published. You will have seen it noticed last week. (D. A. B.).—The Cottage Gardener's Dictionary "is not published at our office. No additions have been made to it since 1856. (J. P. G.).—The "Cottage Gardener's Dictionary" not having had any additions made to it for the last ten years, does not include "all flowers now in cultivation."

PROPAGATING BEGONIAS AND GLOXINIAS FROM LEAVES (H. S.).—Fill a well-drained pot or pan (the latter is best for Begonias), to the rim with a compost of sandy peat and loam and silver sand in equal parts, and cover the surface with a thin layer of silver sand. Take a Begonia leaf which is about half or three parts developed, cut away the leaf-stalk to within half an inch of the blade, and insert the remainder of the leaf-stalk close to the rim of the pot or pan. Lay the leaf flat on the surface, and peg it down closely so that its nervures may be slightly imbedded in the soil, and the whole under-surface level flat. For Gloxinias the pots should be prepared in the same manner, only the leaves must be put in around the sides of the pots like cuttings, and with their lower ends from three quarters of an inch to an inch in the soil. Give a gentle watering, and place in a mild hotbed of from 70° to 75°, and a proportionate top heat. Maintain a close and moist atmosphere, and shade from bright sun, keeping the soil moist but not wet. The Begonias will form little plants along the midribs of the leaves, and when of sufficient size the young plants may be taken with their roots, cutting the midribs on both sides, potted singly and retained in heat until established. The Gloxinias will form tubers beneath the soil, and be well rooted in six weeks. They should then be treated as old plants, and dried off towards autumn. In spring they may be potted off singly, and shoots will come from the crown of the roots, and if grown on, flowers will follow in due season.

DESTROYING COLTSFOOT AND WILD GARLIC (J. N. P.).—Your only plan will be to have the ground cleaned by a thorough ploughing and scarifying, and then grow a root crop, as Swedes; or you would do it much better with a year's fallow, frequently ploughing and dragging the ground. If you were to have the field well worked for a year, and in the following spring have it cleaned by manual labour, using steel digging forks to bring up the roots, and then took a root crop which required clean tillage, you would do much to clear the ground. After another cleaning from the roots of the weeds in spring, the land might be sown with grass seeds, or another root crop might be taken.

WIREWORMS (T. P.).—In No. 69 of our Old Series of THE COTTAGE GARDENER are drawings of the wireworm and its parent beetle, with notes on the modes of trapping, &c. These are all very uncertain. The mole feeds on them. If we had a garden much infested with wireworms, especially if the soil were rather clayey, we would pare and burn 2 inches in depth of the whole surface.

LIQUID MANURE FOR CELERY (M. A. H.).—When young the plants should only have water, but that abundantly. When trunched out, as you wish to grow large heads for exhibition, you might apply the drainage from a pig-stye or stable, diluted with an equal quantity of water. In the First Volume of THE COTTAGE GARDENER, page 193, are full particulars of a very successful mode of growing Celery for exhibition.

CUCUMBER LEAVES INJURED (T. H. J.).—We found no insects, but just a possible trace of thrips. We think the markings might be made with sun heat when little or no air was given.

WHITE BEDDING PLANTS (Blumen).—Centaura candidissima and Cineraria maritima are the best white-leaved plants, and the Cerastium tomentosum is the best dwarf. The Cineraria offsets or cuttings, when they become plants, will be richer in colour than seedlings. Brown's "Forester's Guide" will suit you.

INSECT ON PEACH SHOOT (E. S. R.).—Although on your Peach tree it is the Vine scale (Coccus vitis). Brushing it with a creamy mixture in water of soft soap and flowers of sulphur will destroy it.

BLISTERED PEACH LEAVES (Wye-side).—This distortion is evidently caused by a bursting of the sap vessels in the leaves by exposure to the late spring frosts. Peach trees under glass never are affected with blistered leaves. Thanks for the seeds.

GARDENIA NOT FLOWERING (H. G. E.).—The plant is, perhaps, in too high a temperature, and has not been sufficiently rested in winter, for it expands its blossoms very freely if afforded a mild bottom heat. We grow our Gardenias in a vinery and plunge the pot in February in a bed of tan, and they bloom freely. They require an abundant supply of water when expanding their blossoms, and should be kept dry and cool during the winter; at that season they do well in a greenhouse having a temperature ranging between 45° and 50°.

EVERGREEN OAK NEWLY TRANSPLANTED (E. M.).—We fear you will only save the tree by reducing the head considerably, and this should be done at once. That, and copious waterings during dry weather, are the only measures calculated to keep the tree alive, and we think that the manure will not be of benefit, but, on the contrary, hinder the formation of fresh fibres. No young growths ought to be removed.

SHRUBS FOR PLANTING UNDER FIR TREES (Idem).—The following we find do fairly:—Berberis repens and Darwinii, Berberis or Mahonia aquifolium, Laurustinas, Aunba japonica, common Laurels, Privet, Snow-berry, and Yew, also Rhododendrons, none of which are of very quick growth.

PEACHES AND APRICOTS NOT FRUITING (A Constant Reader).—The cause of your trees not fruiting is the imperfect ripening of the wood, which may be occasioned by the roots being in a cold, wet, rich, deep border. If the trees are not old we advise you to take them up next autumn and replant, not covering the roots to a depth of more than from 4 to 6 inches. The very rich and heavy soil put on the bed would do harm by placing the roots farther from the surface. Bad pruning would not hinder the fruiting, and the frost you say did not injure the fruit. Look to the roots.

WATER MELON CULTURE (A Novice).—Sow the seed now in pots filled with rather strong loam, and place in a mild hotbed of from 70° to 75°. When the rough leaves show put off the seedlings and grow them on treating them in the same manner as Melons.

INARCHING BOWOOD MUSCAT VINE ON WEST'S ST PETER'S (*A Lady Subscriber*).—The flavour of the Bowood Muscat would not be altered by inarching it on West's St. Peter's; but it would not force so well as if it were inarched on the Black Hamburgh, for West's St. Peter's requires nearly, if not quite, as much heat as a Muscat. The Bowood Muscat would do well on the Black Hamburgh for forcing or any other purpose, and its fruit would keep as well as if West's St. Peter's were employed as the stock.

PLANTING VERENAS (*F. J.*).—The Verenas, to make a line in a ribbon-border from 9 to 12 inches wide, should be planted at these distances apart, according to size.

HYACINTHS IN BEDS (*Item*).—Your soil being light and well drained the Hyacinths would not be in the least injured if left in the ground. In autumn you may take them up, remove the small offsets, dress the bed, and replant on the same day. If the soil be wet you may take them up immediately after the foliage has turned yellow.

COCA-NUT FIBRE REFUSE AS A MULCH (*Item*).—The cocoa-nut fibre refuse, and not the fibre, should be put around Rose trees. It resembles brown sawdust. Do not use the fibre, which resembles bristles. The refuse dust would form an excellent mulch for Carnations.

CUTTING GRASS WITH A MACHINE (*Item*).—The grass is best cut when dry, or when the dew is off in the morning. A slight amount of damp is not objectionable. We have not used the machine in the evening with advantage, for the labour power then lags.

CANNA INDICA (*R. H.*).—The soil most suitable for this out of doors is a moderately light loam, enriched by a dressing of leaf-mould and well-rotted manure; but any description of soil will do if it is in good heart and not a stiff, cold, wet clay. The situation should be warm, and, though open, it is best if sheltered from westerly winds, which injure the foliage. Well-laden off before planting out.

DATURA METELOIDES FLOWER-BUDS FALLING (*Datura*).—We think that the flower-buds fell from warmth and dryness inducing red spider, and from want of sufficient moisture in the soil. A moderately light and well-drained soil enriched by a good dressing of well-rotted manure or leaf-mould is best. During dry weather, and particularly when swelling their buds, the plants require to be well watered. The plants which you keep in a greenhouse should be well syringed to keep down red spider, giving a light and airy situation.

CANNA TUBERS NOT GROWING (*Item*).—The Canna tubers have probably lost the eyes; but they will sometimes not start until late in May. They ought to have started before this in a hotbed.

CHARLES LEFFEVRE ROSE WEAK (*Item*).—The plant is very weak. You will do well to cut it and the dwarfs in pots closely to two eyes, and when these break retain the stronger, rubbing the other off.

DECIDUOUS CYPRESS (*Item*).—The deciduous Cypress is *Taxodium distichum*, and the specimen you sent belongs, as you suppose, to that species. The Evergreen Cypress is the Upright Cypress of the south of Europe, and is known as *Cypripis sempervirens*. The Deciduous Cypress, or *Taxodium distichum*, is a native of North America. *Taxodium*, or Sequoia, sempervirens, is the Redwood or Bastard Cedar.

ORCHARD-HOUSE ASPECT (*Inquirer*).—For a span-roofed house let its sides face as nearly as possible east and west. For a lean-to, the nearer one side faces the south the better.

GOLDEN-LEAVED IVY GERANIUM FOR EDGING (*Hedera*).—Plant 14 inches from the edge, and the plants from 9 to 12 inches apart.

ARRANGEMENT OF A GREENHOUSE (*John Bull*).—We approve of your raised border at the back of your house, and the planting it as you propose with six Camellias; but you will injure your Camellias by having creepers above them also on the wall, which is only 12 feet in height. The *Stephanotis* will not do in winter in a temperature of less than from 55 to 60, and that would be too much for the Camellias. You might have two brick pits, say 18 inches square, at each end of the border at the back, and in these plant *Pasiflora Colvilli* and *racemosa caerulea*, and take them along the top of the wall until the Camellias filled the place. The other trailers you may want we would put against the rafters of the roof of the house. The house would be best with a walk all round, the border at back and shelf in front, which would leave you room for a three-feet bed or stage in the centre.

STRAWBERRY FOR AN EAST BANK (*W. B. W.*).—Most varieties would do well on the bank if the soil is good. We have had Black Prince, Keen's Seedling, and Carolina Superior doing well on not very steep slopes. For a very steep and dry bank the most suitable are the Alpine Strawberries.

PURPLE SPINACH (*Item*).—The name of Purple Spinach is *Atriplex hortensis ribes*. It may be sown now in drills as for Spinach, and the seeds covered with light soil. When up thin out to 6 inches apart. To become bushy it requires to be frequently stopped, though when allowed to grow it forms a fine plant 4 to 6 feet in height on good soil, and is very handsome, having a sub-tropical appearance. The inflorescence is curious, and equally ornamental with the foliage.

LOBELIAS FALLING (*J. C. M.*).—We can only account for the Lobelia cuttings falling from your putting in the flowering parts, and we have not the least doubt they dropped off from keeping the soil very wet. We find that old plants do not give cuttings that take root so freely as those from plants a year or so from the seed. Our practice is to save the best of the plants raised from seed in the spring, colour, size of bloom, and compactness of plant guiding the selection. If taken up with bulbs in autumn they winter more safely, and give stronger and better-growing cuttings. Lobelias may be continued by cuttings from year to year, but the plants wear out, and most of the failures of Lobelias are to be attributed to this. Put in more but strong cuttings of the parts not showing flower. They will grow well.

ANTS—WIREWORMS (*J. P. E.*).—For ants, see what we said in our last Number, page 353. For wireworms, see what we say to-day in answer to another correspondent.

NAMES OF PLANTS (*J. B. B.*).—1. *Drymoglossum piloselloides*; 2. *Asplenium marinum*; 3. *Athyrium Filix-foemina var. cristata*; 4. *Asplenium eborense*; 5. *Nipholobos Lingia* (*Barbarea*);—*Daphne ponicica* (1012).—1. *Polypodium vulgare*; 2. *Saxifraga crassifolia* (*H. G. E.*).—The shrub is *Forsythia viridissima*, and the bulb a variety of *Narcissus pseudo-Narcissus*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 12th.

DATE.	BAROMETRICAL.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY AS A SOURCE OF INCOME.

POULTRY is something more than it appears to be in the show-yard. Without desiring in any way or measure to take from the pleasure of exhibiting, or to deprive it of its character as a hobby, we cannot but think of poultry also as an article of food, more especially now when the subject seems to be forced upon us.

Carried to the full extent of its capabilities, poultry would contribute largely to the food of the country, while rearing it might eke out a scanty income; but we are afraid we must give up the last. It would almost appear that those who suffer from the most inconvenient ailment of small incomes are also subject to constant attacks of false pride, which forbid them to use any efforts to increase their means, except such as come within the scope of positive gentility. When a subject like that we are writing upon is mentioned, they rejoice in their ignorance, and protest "it is a thing in which they do not take the slightest interest," while they wonder at opulent neighbours who follow such things zealously. As indications

of character, perhaps the fact that they do may also explain the difference in the means of the two parties.

There is, however, another class who have made a feeble attempt, and given it up at the first disappointment. There is in this, as in everything else, something to learn from those who do for a livelihood that which is followed as a hobby by others.

We often think it would be wise if poultry-keepers followed the example set them by the gentry and many of the nobility, who, at Covent Garden, become the rivals, and often the successful rivals, of the professional growers of forced fruit and vegetables. We know a titled lady in the midland counties who pays all her poultry expenses, and has a profit left from the sale of eggs alone. We will grant this may be an exception, but we look with the greatest pleasure on the practical utility of the balance-sheets that appear from time to time in our columns. A paragraph of practice is of more worth than a volume of theory. Every one of these balance-sheets will make a convert, and each of the latter will add to our stock both of food and knowledge.

What is the cause of the disappointment of those who have given up keeping poultry after one failure?

First, Having heard that spring chickens are unusually dear,

and having three hens that have promising broods, there is a sort of Alnaschar calculation—"Each hen has ten chickens, and these are worth at least 4s. each. For thirty chickens this will be £6; the hens will lay again directly, and second broods may not make us much, but they will sell well—say half price, that will be £3; extra eggs will pay expenses, and my three hens will pay £9, £3 each." This dream is not realised, and then the pursuit is thrown up in despair, and that which affords a pleasant employment and will realise a small but almost certain return, is relinquished, because it will not carry out an ideal profit.

As market poultry will be that which finds a certain sale, we would speak of it. It is with poultry as with everything else, that which is produced in advance of its regular season is the most remunerative, but there is one universal condition tacked to all—it must have maturity. Thus, in the month of April, there are tens of thousands of spring chickens about; they are spring chickens, inasmuch as they are hatched in the spring; but they are not saleable for lack of size till the summer; they are not fit for market till June. The spring chicken that is valuable must be mature and fit for table purposes in April and May. It must be of good size and fit for sale in the spring, being as large as it would naturally be in the summer. This quality makes its value. The small spring chicken, so called because it is hatched in the spring, does not bring the largest price because there are thousands like it; but that which is hatched between November and February, and fit for market in April and May, having all the quality of the spring chicken and the size of a fowl, is valuable, and realises a large price because it is rare. Size is gold when joined to youth and good quality. We believe this will give the key to many past disappointments and prevent future ones. Those, however, who cannot give the attention necessary for rearing and fattening spring chickens, will find summer fowls remunerative. The demand for eggs and poultry generally increases yearly, and there is no doubt it will find a ready sale at all times. The fact of supplying the market does not interfere with exhibiting. On the contrary, the winners of the winter may often be chosen from among the market chickens of the spring.

SOUTHERN POULTRY SHOWS.

This is a subject which possesses peculiar interest to the exhibitors and lovers of poultry residing in the part of England south of the midland counties. The different letters which have appeared concerning poultry shows in the south have, I am thankful to say, ended in something better than words. Permit me a little space about a show that is to take place near Bristol in August next. I ask this, as our good friends in the north can walk alone, nay, do run alone, on the poultry show subject; but in the south there needs every encouragement and help, even the little my pen can give.

There is, then, to be a Show on the 22nd of August at Kingswood, near Bristol, attached to the Cottagers' Horticultural Society, which it appears comprises six parishes. This Society was only formed in 1864; but it is not only youthful but vigorous. It has this year been determined "to add to the attractions of the Society's programme an exhibition of domestic poultry; and to enhance the value of such exhibition, and to enable the cottager, for whom this is more particularly intended, to judge of the merits of first-class poultry, it has been resolved to offer prizes open to all England." This is well. In other respects all seems promising. Patrons, Vice-Presidents, and Committee are numerous and influential. There are special prizes for the cottagers' flowers and fruit—sensible useful prizes; among them "a pair of boots [I hope they will fit the winner], a set of garden tools, a spade, and a prong for working potatoes." May it never turn up a diseased one! Now, these prizes are a thousand times better than useless things. When I turn to the poultry part of the schedule I find for the cottagers of the district suitable money prizes, with an extra 10s. for the best pen. Then come prizes of 10s. and 5s., first and second class respectively, for amateurs; and "open to all England," first prizes of £2 2s., and second of £1 1s. These will doubtless draw together some excellent birds. But this is not all. Mr. Rodbard offers "two prizes of the value of two guineas and one guinea for the best cockerel of any variety, to be exhibited separately." Thus, then, all appears very favourable. May it be fine weather, may there be plenty of birds and plenty of visitors; and then I am sure

we shall enjoy Wednesday, 22nd of August, at Kingswood.—
WILTSHIRE RECTOR.

As one who has repeatedly grumbled at the non-existence of southern poultry shows, which, in the words of our Prime Minister, have indeed been "conspicuous by their absence," allow me to congratulate my brother fanciers that "the old order changeth," and that henceforth we have the promise of a better state of things. I take up the last Number of "our Journal," and instead of having my bile disturbed, as the "WILTSHIRE RECTOR'S" was by reading with dismay a long list of Yorkshire shows with outlandish names, culminating in that crackjaw name of Heckmondwike (!), I now see with a gradually broadening smile of satisfaction a goodly list of southern, eastern, and western cities, shortly to echo with the "cock's shrill clarion." There is Woodbridge, in Suffolk, with its working Secretary Mr. Dallenger; and a "genuine fellow," a thorough poultry-fancier, is Mr. Wright. Then there are Bury St. Edmunds, and Chelmsford, and Ipswich. Bravo! say I, to the pluck of the East Anglian fanciers! Turning southward—we will not stop at Maidstone, a "close borough," I fear, as regards poultry, limited with sundry other restrictions to Kentish fanciers; and Poking, where they only show Dorplings!—we pass with a sigh the Crystal Palace, scene of former glories, tempting one to paraphrase Moore's lines, for there, indeed—

"We seem like one
Who treads alone
Some poultry show deserted;
Whose guests are fled,
The chickens dead,
And the manager departed."

Proceeding southward Brighton offers a more cheering spectacle; and though last year the cattle show there, given up on account of that delightful "rinderpest," carried with it in its ruin the poultry show, still we have reason to hope that another Brighton show will rise like the phoenix from the collapse of the old one. The "South of England," at Shoreham, greets us with a high-sounding title. May it float as lightly on the waves of success as the name of its projector, Mr. Cork, would bid us augur! But, Westward, ho! for the stately spire of Salisbury attracts us to that ancient city. There in a few weeks will be gathered such a "cock parliament" from all parts of England, as to make old "Mother Birmingham" herself jealous! But from the more distant west we hear of other shows. Kingswood by smoky Bristol has raised its standard. Cidne has a well-earned name for the love of fowls, and a Gloucestershire show blooms in the future! Southampton, too, is "no mean city" for a gathering of the feathered tribe. Lastly, I must not pass over one of, if not the very best of, southern shows, and which may be pronounced in the language of the poultry judges, to be "good at all points!" Thrice in three consecutive years has the writer journeyed, on a pleasant summer's day, to the annual gathering of the North Hants, now the "Hants and Berks Agricultural." Twice at quaint old Basingstoke; once at scholastic Winchester did we show our respect for the Show, and give ourselves a treat.

"Hæc olim meminisse juvabit."

We will not say "what our birds did," as we wish to be modest and leave all the "crowing" to them. But we will say, that though our day at Winchester followed the day upon which, like all the world, we kept what "Punch" calls "the feast of Darbee" upon Epsom Downs, yet the Winchester day was to us as jolly as the other! Remember that we (for there were a party of us), were poultry fanciers! Now, Mr. "WILTSHIRE RECTOR," we all owe you a good turn, for "many's the time and oft," that you have entertained us; so here is a winkle for you in return. Go and see the "Hants and Berks" Show at Reading next month. If it is at all like its predecessors, you will find your fare from Wilts a good investment, repaid in what I know you like—seeing folks enjoy themselves wisely and well! To my brother fanciers let me say, You have a liberal prize list, good accommodation for birds, a first-rate Judge, and in Mr. Henry Downs, the "Head Centre" of this (not Fenian lot), Poultry Brotherhood, a most obliging and able Manager. A good list of prizes calls for a good entry, and a good entry or collection is well worth looking at. So when the 15th of June arrives, may the weather be "royal," and may I with all who love poultry "be there to see!"—
BRAMMA PONTIA.

We, southrons, must rejoice in the prospect held out in your

last week's Number by "W. B." I trust that all of us will try by good entries to make the show a success, and then probably we may have it annually. How our friend "Wiltshire Recror" must rejoice at the prospect! His "grievance" seems really to be dwindling away. Why, here, he will have Salisbury and Reading, and now a show proposed in Gloucestershire! Still, much of the success or otherwise, must depend on southern exhibitors coming forward freely as competitors. I trust "W. B." will be able to induce our local railway, G. W. R., to be "moderate."—Y. R. A. Z.

RAILWAY CHARGES.

I SHALL have altogether about 110 names to append to the memorial; all, with the exception of those subjoined, having already appeared in the pages of "our Journal," it is useless occupying the space by again inserting them or the memorial.

I have to thank your correspondent Mr. P. Warren for a very valuable suggestion; and I will immediately put in hand another memorial, to be signed by officials of poultry shows. I should only be too glad to receive the names of persons who would undertake the presentation of these memorials, but as yet I have only heard from one person; in default, I must be content with the post-office. It is only since I have been mixed up with this effort that I have learnt the great value of birds to railways. Why, on some lines they are far more valuable than passengers. One exhibitor writes me that if he goes by third class from his place to London he is charged 1*l.*; if he takes a bird with him the bird is charged 3*l.*; if he sends the bird and books it, 9*l.* Under such circumstances the shareholders possibly sing, "Would that all passengers were birds!" "Punch" may well dress the Cochins up in trowsers as men, they are more valuable sometimes.

The following are the additional names;—

- | | |
|------------------------------|--|
| Rev. H. J. Bailey. | Mr. Charles Cowlam. |
| Mr. Wilfred Bowly, 5, p. 11. | Rev. G. Raynor. |
| Capt. H. B. Lane. | Mr. Matthew Dimsdale. |
| Mr. Wm. Herdby. | Mr. E. G. Phillips. |
| Mr. Francis Bromel. | Rev. F. Taylor, 10s. 6 <i>s.</i> paid. |

—JOSEPH HINTON (Y. R. A. Z.).

EPWORTH SHOW OF POULTRY, &c.

ON Friday the 4th inst. the first Exhibition of Poultry, Rabbits, Pigeons, Canaries and other Song Birds was held at Epworth, in a large marquee, on the premises of Mr. T. Dunbar, of the King's Head Inn, who kindly lent his paddock for the occasion. The Show was a complete success, and even exceeded the most sanguine anticipations of the promoters. Being the first of the kind held in the town, it was partially speculative; but through the indefatigable exertions of Mr. W. N. Hudson, the Honorary Secretary, and Mr. J. C. Adley, the Treasurer, the experiment was crowned with success. The Exhibition was open to all England, and the number of entries was two hundred, several of them from distant parts of the country.

SPANISH.—First, W. H. Wheeler, Carlton, Notts. Second, R. Newbitt, Epworth. Commended, R. Newbitt.

DORKINGS (Any colour).—First, —Sleadmore, Epworth (Grey). Second, A. M. Aspinall, Athorpe, Grey. Highly Commended, —Sleadmore (Grey); W. Harrison, Belton; R. Bentley, Hatfield Moors. Commended, T. W. Dawson, Epworth (Grey).

GAME (Any variety).—First and Second, F. Styles, Crowle. Highly Commended, W. Harrison (Black Red); J. Hodgkinson, Hull; R. Bentley.

COCHIN CHINA (Any colour). First, W. H. Wheeler. Second, W. F. Josling, Maltesse Cottage, Chelmsford, Partridge.

HAMBURGH (Any variety).—First, C. Marsden, jun. Second, W. Harrison (Golden-spangled). Third, S. Gray, E. Lond (Golden-pencilled). Highly Commended, J. F. Loweridge, Newark, Notts (Silver-spangled). Commended, C. Marsden, jun.; C. Hincliffe, Keadby (Silver-spangled); R. Bentley.

BANTAMS (Any variety).—First, E. Toder, Little Carlton, Newark (Black Red). Second, Messrs. S. & R. Ashton, Mottram, Manchester. Highly Commended, E. Toder (Dorkings). Commended, F. Styles.

ANY OTHER VARIETY.—First, J. Hodgkinson (Brahmas). Second, G. Oldfield, Epworth.

ANY BREED.—Cock.—First, J. Hodgkinson (Pile). Second, J. Rowbottom, E. Hon (Black Game). Third, E. Hensley, Doncaster (Game). Highly Commended, E. Styles (Brown Red Game). *Hens.*—First, —Sleadmore (Grey Dorking). Second, H. Chesman, Epworth (Dorking).

DUCKS.—First, Mrs. Charlton, B. Hon. Second, A. Fallowfield, Epworth. Highly Commended, J. Hodgkinson; R. Bentley.

TWELVE EGGS.—First and Second, J. W. Taylor, Coven, Haxey. Third, E. Nicholson, Epworth Turbury. Fourth, Mrs. E. E. Basing, Epworth. Commended, M. Brandell, Epworth; Mrs. Chas. Holmes, Epworth.

RABBITS (Any colour).—First, Messrs. Hanson & Wagstaff, Thorne. Second, C. Gravel, Thorne. *Back.*—First, Messrs. Hanson & Wagstaff (Black and White). Second, E. E. M. Roys, Ightheld, Whitechurch.

Doc.—Second, Messrs. Hanson & Wagstaff (Sandy and White). *Weight.*—Highly Commended, E. Newbitt.

PIGEONS.

CARRIERS (Any colour).—First and Second, H. Yardley, Market Hall, Birmingham. Highly Commended, R. Bellamy, Leven, Beverley (Black). Commended, Messrs. Hanson & Wagstaff (Black).

POWERS.—First, F. Key, Beverley. Second, E. Brown, Sheffield. Highly Commended, C. Adley, Epworth (Red). Commended, C. Adley (Black).

TEMPLERS.—First, E. Brown (Almond). Second, R. Bellamy (Almond). Third, C. Gravel. Highly Commended, —Lowther, Doncaster. Commended, —Lowther.

FANFALES. First, F. Key. Second, H. Yardley. Highly Commended, —Taylor, Middlesborough. Commended, —Lowther.

JACOBS.—First, Messrs. Adley & Brock, Epworth (Buff). Second, H. Spenshall, Gedney. Highly Commended, Miss Taylor, Temple Belwood (Yellow). Commended, H. Yardley.

BARRS.—First, G. Woodley, Thorne. Second, H. Yardley. Highly Commended, E. Brown, Sheffield. Commended, C. Haverfort, Thorne.

ANY OTHER VARIETY.—First, F. Key (Trumpeters). Second and Fourth, H. Yardley. Third, C. Adley (Owls). Highly Commended, E. Brown, (Swiss). Commended, Messrs. S. & R. Ashton.

SONG BIRDS.

CANARIES.—Cock.—First, G. Crosby, Epworth. Second, Miss M. Hunter, Thorne. Third, R. P. Read, Epworth, (Marked). Highly Commended, J. Smith, Epworth (Yellow); W. Harrison, Belton (Yellow). Commended, Miss S. Hurtle, Leeds (Green); J. Smith, Epworth (Yellow).

GOLDFINCH.—First, J. Wrigley, jun. Thorne. Second, D. Daulmey, Sandlot. Highly Commended, Miss A. Hudson, Epworth.

LINNET.—First, Master W. H. Butterfield, Epworth. Second, J. Wrigley, jun.

ANY OTHER VARIETY OF SONG BIRD.—Cock.—First, T. W. Dawson (Goldfinch). Second, J. Lindley, Epworth (Thrush). Third and Fourth, T. H. Cope, Epworth (Ring Ouzle, Tree Pipit). Highly Commended, L. Clarke, Belton (Mule).

JUDGES.—W. Wood, Esq., of Sheffield, and J. Morton, Esq., of Hull.

IS RYE MEAL A SUBSTITUTE FOR POLLEN?

SOME eighteen months ago I was not a little amused by a discussion which took place in this Journal regarding the carnivorous and omnivorous propensities of bees—whether they could, like "the lords of the creation," dine on roast beef, and breakfast on mutton chop or tender chicken. This grave question having been referred to your valued correspondent "E. S.," was by him subjected to the infallible test of experiment, and the result was a complete acquittal of our little favourites of the gross charge so unjustly preferred against them. Since then, the gustative predilections of bees have again been the subject of calumny, originating, apparently, from an Italian source. In the beginning of the present spring a small parcel was forwarded to me by a friend, containing three very curious-looking cakes. On opening the accompanying letter I was informed these were specimens of rape oilcake for feeding bees, recommended by M. Masso, an Italian apiculturist, who, according to the newspaper paragraph enclosed, made the rare discovery that his bees collected therefrom "balls of provisions which they stowed away, and so continued until the flowers re-appeared in the spring." Very wonderful! thought I; but I shall soon see. I hastened to the apiary, tried it in all forms, but found that my Italian bees had no liking for such bovine food. A few after boggling at it for an instant retired, seemingly much affronted at the indignity offered them.

"But what has all this to do with rye-meal as a substitute for pollen?" asks my reader. "Have you tried it?" Yes, I have, and, like M. Masso's rape oilcake, my bees will have none of it. It is quite true numbers became as white as millers by traversing through it, and several got themselves loaded with regular pellets, the dust having accidentally collected in the little baskets on the thighs, so that to all appearance they looked like bees covered over and laden with the natural pollen of flowers. As these entered the hive I could not help smiling at the completeness of the illusion. I fancied a few tried to nibble at it, but they soon left off, being unable to discover its use.

Such being my experience, I would feel obliged, by any of your correspondents who have tried this alleged substitute for pollen kindly favouring us with the results of their experience regarding it. Dzierzon, I believe, was the first to make the discovery, and so distinguished an apiarian could not, I imagine, be well deceived in the matter. Several other German bee-keepers are also said to have used rye-meal, and likewise wheat, with good results; and Langstroth, too, has indorsed it with his recommendation, though it does not very clearly appear that he himself practically tested its value.

In a spring like the present, unparalleled for its unpropitious and ungenial character, when little or no pollen could be collected from flowers, a substitute, if such there be, would be an invaluable adjunct to the usual kind of feeding resorted to, and, therefore, it is desirable that apiarians should know how far, and in what way, Dzierzon's discovery may be made available, and if yemenal can be really appropriated by bees, and used as a substitute for the pollen of flowers. — J. Lowe.

A BEE-KEEPING NOVIATE.

I PURCHASED A SWARM in a common stock hive on the 4th of June last year. It swarmed on that day, and weighed, with hive and floor-board, 15 lbs. About a fortnight later I cut a hole in the top of the hive, and put on an adapter, as directed in Payne's "Bee-keeping." The top of the hive being round, I had to use some mortar to get a level surface; the mortar and adapter weighed 1 lbs., making the whole weight of swarm, hive, floor-board, and adapter 19 lbs. I put on a super, but the bees did not work in it, and after removing it in September the hive weighed 37 lbs. Whenever I speak of the hive please to understand I mean the whole together, hive, board, and adapter. I now wanted to increase the weight to 42 lbs. by feeding; but now came a difficulty, for I dared not lift up the hive to put food under. I made a small box with one end of glass to put over the hole in the top of the hive. I then took an empty sardine box, which held just half a pound of syrup, and cut a very thin piece of deal to fit it, boring it full of holes. This piece of deal floats in the box, and rises and falls with the syrup. The small box being full, I one evening, with trembling hand, pushed it under the box on the top of the hive; it was soon black with bees, and on looking through the glass in the morning I saw the food was all gone. I at once took it out, and filled it again. But now I found a fresh difficulty. After one or two feeds I found that as soon as I withdrew the box to fill it the bees came pouring up, and when I wanted to push it under again I dared not do so, being afraid of hurting the bees, but considerably more afraid of their hurting me. I then managed in this way: After waiting a few hours I put the box under, and then bored a hole through the top of the large box, directly over the centre of the small one. I then pushed through a piece of indian-rubber tubing, and by means of a small funnel I could then fill the box at pleasure. By these means I fed my hive up to 43 lbs. On the 24th of December it weighed 41 lbs., on January 29th 37 lbs., on March 29th 34½ lbs., on April 16th 32½ lbs., on the 20th 31 lbs., on the 23rd 30½ lbs., on the 25th 30½ lbs., on the 28th 31½ lbs., on the 30th 31 lbs., on May 2nd 30½ lbs., on the 3rd 29½ lbs., on the 4th 29½ lbs., and down to the 8th the weight has been stationary.

Will you inform me whether it is usual for bees to lose weight so late in the season, as I expected them to gain long before this, and whether you think mine are going on all right, also when you think I may put on the super? I wish to prevent them swarming this year. — J. R. BAYTON.

You evinced considerable ingenuity in overcoming the difficulty which you experienced in feeding your bees; but all and more than all the advantages of your apparatus are obtainable in a much more simple and convenient form by the use of an inverted bottle. All that is necessary is a common pickle-bottle, filled with food, and tied over with a bit of cup net, and inverted over the central aperture in the top of the hive, which should be previously covered with a piece of perforated zinc. A perforated block of wood about 5 inches diameter, and fitting closely to its neck, is an important adjunct to the feeding-bottle, obviating, as it does, all risk of a capsise, and effectually excluding marauders.

The recent unfavourable weather is the cause of your bees remaining stationary, and we should regard the first favourable change as the signal for putting on a super.

We know of no work exactly answering your description. Most bee-books give more or less reliable particulars of the natural history of the insect. Much information may also be derived from a perusal of Kirby and Spence's "Entomology," and there are good articles in the last editions of the "Encyclopædia Britannica," and Chambers' "Information for the People." Huber's "Observations on the Natural History of Bees" is still most valuable to the scientific inquirer; whilst full information on the more recent great discovery of parthenogenesis in the honey bee may be found in Mr. Dallas's translation of Von Siebold's work on that subject, published by Van

Voorst, as well as in articles from the pen of Mr. Woodbury, the first of which appeared in our 25th Number, and which were afterwards continued from time to time.

NORTH BRITISH COLUMBIAN SOCIETY. — One of the most liberal prize lists for Pigeons is offered for competition on the 20th of December by this Society. The prizes vary from two guineas downwards, and there are many silver medals in addition.

OUR LETTER BOX.

POULTRY BOOK (*A Beginner*). — If you send seven penny postage stamps to our office with your direction, and order "The Poultry Book for the Many," you will have it sent to you free by post.

REARING BLACK BANTAMS. *Eboracum*. — Feed your Bantam chickens well, nothing is ever gained by starving chickens. Good and proper growth with symmetry are, as necessary and essential as small size. May chickens are often successfully shown in November, especially Cuckins.

DUCKLINGS WITH CONTRACTED FEET. (*Constant Reader*). — The only advice we can give you about your ducklings, hatched with contracted feet, is to give up breeding from the stock, as there are no means of preventing that which happens before birth. Adult fowls seldom or never die of rages. It is very fatal among chickens. Pills of camphor half the size of a pea, given at six or eight hours' interval till the gaping ceases, will cure them, and if the water they have to drink is strongly impregnated with the same drug, it will prevent them.

TURKEYS HATCHED BY A HEN. (*J. M. L.*). — Keep the hen under a rip with bars wide enough to allow the poults to run in and out. Be sure to put it in a sheltered place, so far as cold wind is concerned, but also in one where advantage can be taken of the sunshine. Feed as with chickens, adding to the bill of fare paste made of pea, bean, and oat meal staked with milk and with green onion tops chopped fine and mixed with it. It is essential to keep young Turkeys dry, and beer is a good thing for them.

CHICKENS DURING COLD WEATHER. (*H. B.*). — Good feeding is the only thing we can suggest as the antidote for the cold weather. Beer is much better drink for chickens than water, when the atmosphere is damp and chilly.

COCKS-CHINA PELLETS NESTING WITHOUT LAYING. (*J. J.*). — Her egg-organs are most probably inflamed, and we anticipate that she is too fat. Give her a dessert-spoonful of castor-oil twice after a day's interval. Keep her on mashed potatoes with a very little barleymeal added, but no whole corn or flesh food. Abundance of green food, especially lettuce leaves, is desirable.

INCUBATOR. *T. E. Partridge*. — The temperature should be 104° or 105°. We have not heard recently anything about the Grape you mention. It will be advertised, probably, in due time.

DOUBLING CHICKENS DYING. (*L. B. D.*). — The symptoms are those of rages. Give each chicken a pill of camphor, as directed for another correspondent to-day.

POINTS OF ROVEN DRAKE. (*J. H. C.*). — The bill should be of a yellowish green without any other colour, except the black beam at the tip; long, broad, and rather wider at the tip than at the base. Head, in-troons, green, and purple; distinct white ring round the neck, not quite meeting at the back; rich brown or claret breast, reaching low down to the water line. Back, dark green; body, soft, grey, almost white near the tail; tail, dark green, and curls firm and black; wings, brownish, with broad ribbon mark of purple and white; white flight feathers are a fatal defect; legs, orange, or brown and orange; weight about 8 lbs.

GUINEA FOWLS. (*J. Richardson*). — The eggs require from twenty-eight to thirty days for hatching. If you send seven postage stamps with your address, and order "The Poultry Book for the Many," it will be sent to you free by post. It contains the information you mention.

FRAME HIVES—GUIDE-COMBS. (*F. H.*). — In the absence of guide-combs a very efficient substitute may be found in the German artificial combs or impressed wax sheets sold by Messrs. Neighbour. These should be cut into strips of 1½ inch in width, and fixed on edge to the under side of the bars by means of melted wax. The best means of doing this is by making incisions a quarter of an inch deep and about 1 inch apart along one edge of the strip of wax, which should be held between two slips of wood with the incised edge projecting and slightly warmed by a fire; then gently bend the incised portions at right angles in opposite directions right and left, rapidly wax the bar with melted wax, and quickly press the bent portions of the incised edge upon it. If properly managed these strips of artificial comb will adhere firmly and form most efficient guide-combs. When natural combs are used for the purpose they should not be old, and all drone-combs should be carefully eschewed. The latter end of April is usually about the time for putting on supers, but no exact period can be named, as it is always varying with the season and the state of the stocks themselves.

POULTRY MARKET.—MAY 14.

In common with other markets, extreme dullness causes unsatisfactory trade, and lower quotations. We do not recollect so bad a trade in the month of May.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 66.9°; and its night temperature 43.9°. The greatest heat was 91°, on the 23th, 1817; and the lowest cold 25°, on the 23rd and 26th, 1863; and 23rd, 1864. The greatest fall of rain was 0.97 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

PLANTING OUT SUB-TROPICAL AND OTHER HANDSOME-FOLIAGED PLANTS.

LONGST my regrets is the very great one that I have not had the pleasure of seeing the results accomplished in this way at Battersea Park—results which, in their mag-

nitude and the harmony of their arrangement, seem to have eclipsed all that has been done in that way formerly. I trust that this season I may be able to admire and take notes of such arrangements, and also learn whether I have before met with Mr. Gibson, to whom the public are so much indebted for bringing together such fresh combinations of the beautiful. Perhaps I could value such combinations all the more, though as yet depending on mental vision, as, though of late years I have done little in this way, and this year will be likely to do little or nothing, it is more than thirty years since I noticed what might be done by planting out greenhouse and the hardiest of stove-plants in summer; and for a period of some fifteen years I did less or more of this every year, when such combinations were not at all common. Then, as now, what I did, even on a limited scale, was much noticed by those who admired beauty in form as well as in brightness of colouring.

In answer to the many inquiries why I do not continue a system the full value of which no one would be more ready to recognise, I will not enter into the economical questions involved, but will content myself with stating that our little space under glass began to be more occupied with the useful as respects the table instead of the merely beautiful; that our lawn is so open and exposed to winds, that all large-leaved plants, as *Cannas*, *Brugmansias*, *Castor-oil plants*, &c., even with the greatest care, were liable to have the foliage cut into unseemly ribbons; and that the position formerly appropriated chiefly to this purpose became by degrees too shaded to suit the original intention, and other places that would have been suitable have for the present been devoted to other objects.

The place where the sub-tropical plants thrive admirably was enclosed by raised banks, running chiefly east and west, though bounded also on the east and west, the banks crossing each other so as to permit of suitable entrances. These banks were planted with Laurels, *Pinus*, &c.; and as long as they merely kept out the winds and admitted the sun, the plants did remarkably well. The beds in the centre were raised chiefly by flints; and a sunk fountain or cistern in the centre was made with flints set in cement against brick. Most of the flints round the beds and round the boundary that supported the banks were covered with *Mesembryanthemums*, *Sedums*, *Saxifrages*, &c. No doubt

the flints helped to absorb and retain heat in these elevated beds; but to increase this heat before planting out, from the middle to the end of June, we used to turn in the soil a spit deep in the afternoon after a sunny day and for very tender plants, in addition to this, we used to take out a good hole, and fill it with hot fermenting dung and some 6 inches of rotten dung over it, and then the soil, in which we either planted at once or plunged the pot or tub. As the place gradually became more shaded these sub-tropical plants were confined to the sunniest spots. The whole effect, even on a limited scale, was very good; the tallest and freest-growing plants being placed far enough apart, either singly or in groups, to show themselves off well; whilst those of less growth were placed in smaller groups or singly between the tallest, and the ground was carpeted with *Rock Roses*, *Sedums*, *Cerastiums*, *Cineraria maritima*, &c. But for the general flower-beds being so open, the fine-foliaged plants might be mixed with good effect in the combinations of the bedding plants; but to show how windy the place is, *Colerus Verschaffeltii* was torn into ribbons, and *Cannas* and *Ricinus* were so nicely fringed that a person would have imagined it was their natural condition.

That others may have the opportunity of doing what at present I cannot do myself, and thus give a sub-tropical appearance to a part of their grounds, I will subjoin the following list of what I have either used myself or seen successfully used, with some short hints as to their treatment, merely promising that much of the success will depend on having plenty of sun heat, protection from winds, and the ground in a warm state, by whatever means accomplished, before turning the plants out; and also, that though many will do well in pots plunged, with outlets for the roots, the greatest vigour will be obtained, and less trouble will be required in watering, when the plants are turned out into the soil, merely breaking the outsides of the ball a little.

1. *ACACIA*.—Several of the fine-foliaged ones, as *mollis*, *pubescens*, *decurrens*, *lophantha*, are very useful and effective when so treated. I used to plant them out into rich compost, train them to a single stem 6 or 8 feet in height, and let them branch there; in October raise them, squeeze the roots into a large pot, cut in the head, water well, set the plants in a shady place until the roots began to run, and then house them for the winter in a shed where there was a stovehole. I pruned in the head pretty closely in spring, and exposed the plants in a sheltered place in April. In this and all similar cases the plants should not have much artificial heat before being planted out.

2. *ARALIA*.—The beautiful *Aralia papyrifera* I had not the chance of so using. It would make a fine centre to a group. The hardy *spinosa*, which grows 8 or 10 feet high, has an effective appearance. The pretty *Sieboldii* is very effective, and in a dry place would need only a little protection in winter.

3. *ARTUSIO*.—*A. donax* is one of the finest Reed-looking plants, throwing up stems strong enough for stakes. It is very shy of transplanting. This is best done just before it

begins to move in spring, and people must generally be content if it keep alive the first season. It likes rich loamy soil and plenty of moisture. *Arundo donax variegata* is pretty, and nearly as strong-growing. *Arundo versicolor* is a universal favourite, as the striped Grass called Gardeners' Garters; and one of the most wonderful things about them is, that though I have carefully examined some thousand blades, I never could find two striped alike. The Garters make a good edging to tall plants, and by frequent cutting and plentiful watering they will retain their freshness to the end of the season.

4. *AMARYLLIS*.—Of this there are three sorts worthy of attention—*melancholens*, the common edging or bedding soft purple leaved plant; *bicolor*, with two colors in the leaves; and *tricolor*, with three bright colours, one of the prettiest plants we have. I never did any good with it out of doors, except in the bank-protected place alluded to. The seed of all should be sown in March in a hotbed, and the seedlings be pricked-off, and hardened off for planting out in June.

5. *BRUGMANSIA* OR *DAKOTA*.—Perhaps of the best are *succulens*, with large green leaves, and large trumpet-shaped single white flowers, and *Knightii* the same, with double flowers, and both sweet-scented. The next best are *lutea* with yellow flowers, and *atropurpurea* with dark crimson flowers, and the foliage of both less attractive. These may either be grown as bushes or as short standards, with stems from 1 to 7 or 8 feet in height. In this last style the large flowers show to the best advantage. In May turn out into rich compost, and water during the season. In autumn take up, prune in the shoots to half their length, and in spring, after keeping the plants in any place recover from frost, prune back within a few buds of the base of last season's shoots; expose by the beginning of May where protection can be given them, and when turned out in the end of the month they will produce their flowering shoots from the middle of July and onwards.

6. *CENTAUREA CANDIDISSIMA* AND VARIETIES.—Beautiful for edgings, and for blending with scarlets, crimsons, and purples. Take cuttings in July, or put in small bits in heat in spring. Treat as respects protection like other bedding plants, giving little pot-room, and little water in winter.

7. *CHEXORODIUM ANPLEX* AND *PURPURESCENS* do best when sown under glass, potted-off, and planted-out in May, and make strong plants of a purplish hue.

8. *CINERARIA MARITIMA*.—Fine for edgings and undergrowths for *Coleus*, *Cannas*, &c. It is most easily propagated in spring from short stubby shoots or suckers, in a little mild heat. In rather dry ground it is usually hardy, but young plants generally answer best, as they do not so readily throw up their flower-stems, and, therefore, they are more compact.

9. *CASSIA COBYBOSA*.—In addition to the splendid yellow masses of bloom and the fine green foliage, this furnishes a good example of leaves folding themselves back and sleeping at the approach of evening. It is treated like the *Araucias* and *Brugmansias*, only it requires a little higher temperature in winter, but it does best when not too far advanced when it is planted out. It succeeds best every way when planted out.

10. *CALADIUM ESCULENTUM*, *CALADIUM*, &c.—The safest plan would be to turn them out in July in heated soil, and take up and keep in a dormant state all winter; but I should like to try *esculentum* in the ground with a large hand-light over it, and a hood of straw in severe weather. However, that would be more trouble than taking it up. The bulk of the family will neither stand much cold nor damp in winter, or, if damp, they must not be cold. A temperature of about 65° is safe.

11. *CANNA*.—The varieties and so-called species are innumerable, and all bear bright flowers peeping out through large foliage. The plants grow from 18 inches to 3 and 5 or more feet in height. Perhaps the finest for foliage are *bicolor*, *discolor*, *nigricans*, *zabrina*, *Livardi*, *Lamberti*, *mutabilis*, *mus-folia*, *hybrida*, &c., but all are beautiful when grown in a warm sheltered place where they can have plenty of sun and little wind. They do best when planted out in June, when they have not grown much to make them tender, and by the end of October they should be taken up and potted, some leaves left to encourage rooting, and then have all the stems cleared away and the roots plunged in dry earth in a shed by Christmas, and there they may remain until April. They merely need to be protected from frost in winter when used for out-door work.

12. *COLEUS BLUMEI*, *VERSCHAFFELII*, &c.—Beautiful plants for a warm place. In cold open places they rarely do well. They make nice bands for *Cannas*, &c., and blend well with *Cineraria maritima* and *candidissima*. They do best when raised

from cuttings every spring in a hotbed, and then hardened off gradually until June, and turned out into earth well heated by the sun.

13. *DICKSONIA ANTARCTICA*, &c.—These fine Ferns do best planted in their pots, or tubs, with drainage below to prevent stagnation, and the surface covered with moss or *Selaginella*. Thus treated many Ferns might ornament our flower gardens, and especially the sub-tropical department, in summer.

14. *DROSERAS*.—These must be lifted in time.

15. *EPICAMPYRUS ROBUSTA* and other Gum trees present a singular appearance from their foliage, &c. I am not aware that any will stand our climate without the protection of a wall, but they do pretty well when treated as described for *Araucias*.

16. *ERIANTHEUS RAVENNE*.—This ornamental Grass will look after itself when established, and like the *Pampas* Grass shows best by itself.

17. *FICUS ELASTICA*.—The Indian-rubber plant is not half so common as it ought to be. Plunged in pots, or planted out and carefully taken up in October, it may do for many years, if the temperature in winter is rarely below 10°, and never at freezing point. Propagated by cuttings and suckers. The juice should be allowed to dry before inserting the cuttings, and the plant should be dry before they are taken off.

18. *GYNERIUM LANTANUM* does well with its hoary leaves and shoots for edgings and carpeting the ground. It is propagated by cuttings, and should be kept in a pit or greenhouse in winter.

19. *GYNERIUM ARGENTEUM*.—All the varieties of the *Pampas* Grass will take care of themselves in ordinary winters. Propagation is effected by seeds and division of the plant. It is seen to most advantage when planted by itself on a knoll with its pendent grass sweeping over it, and the flower-stems standing alone in their glory.

20. *IBIDEXIA*.—All the variegated and the smaller-leaved Ivies are useful for edgings and carpeting the ground in such places.

21. *HELVETIUM*.—I have never done much with coronarium out of doors, but have had fine spikes of bloom and noble foliage of *Gardnerianum* in a sheltered place, when planted in rich soil, with two or three barrowloads of good hot dung beneath it. The roots were taken up and treated only a little better than those of the *Canna*.

22. *IRISIN HERBERTI*.—A good edging plant, or for small groups between larger plants, as recommended for *Ananthurus tricolor*; cuttings strike freely in heat.

23. *LOBATIA FERRUGINEA*.—A protected plant with fine foliage, of which I have had a good account, but which I have never had the chance of trying.

24. *HELIANTHUS MAJOR*.—The flowers seldom show, but the leaves have a graceful heaviness about them, and smell when touched much like peas-meal. I have seen good plants stand some years against a wall, and a plant did well for a time in our little protected place. We took it up in October and kept it in a cool greenhouse in winter. This grows from 8 to 10 feet in height. *Minor* is a dwarf variety.

25. *MESEMBRYANTHEMUMS*.—Many of these are very beautiful for setting on decayed stumps, rotten stones, and also, like the pretty Californian *Honsleek*, will make nice edgings for small, low-growing groups.

26. *NEOTIANA*.—Most of the *Tobaccos* have fine foliage, and the aroma given off is very grateful to the lovers of the weed. The new *Neotiana wigandioides* is very attractive. They are raised from seed sown on a hotbed in March, and the seedlings hardened off before planting out.

27. *NERIUM* (*Oleander*).—The white, pink, single and double green, and variegated, do better in such a sheltered place as described than in pots. If plenty of shoots on large plants are encouraged they bloom well every year. The taking-up, and moderate dryness afterwards, seem to secure the free-blooming in the following season. The plants must be kept rather dry and free from frost in winter. In fact, where much of this planting-out of large plants is resorted to, houses like our old granaries are wanted merely to preserve the plants in life rather than to grow them.

28. *RICINUS* (*Castor-oil plants*).—This is one of the most effective families for the purpose where there is room to display them, and the wind is kept from tearing and ribboning the fine parasol-like leaves; many kinds, such as *bourbonensis*, have fine shaded foliage as well as coloured stems and fruit. Among the best are *communis*, *macrocarpis*, *spectabilis*, *variabilis* *splendens*, *sanguineus*, *tricolor*, &c. These may all be grown to a good size, say from 5 to 8 feet. There are also dwarf varieties of less than half that height, as *viridis*, *spino-*

sus, niger, &c. I have taken up these splendid plants and tried to keep them over the winter; but unless a warm place can be afforded them, the trouble is next to wasted, as in a cool place they will always be getting less and less. I have found this plan of keeping them over the winter suitable when, instead of a plant with one strong stem, I wished to have a bush with five, seven, or more stems, for by cutting back the kept-over plant, say a foot or 15 inches from the ground, growing it on vigorously in spring, and hardening it off, a fine massive bush might be obtained. For general purposes—that is, to have stout single-stemmed plants with huge healthy leaves, the best plan is to sow the beautiful bean-like seeds early in March in a hotbed, pot off the plants when a few inches high, and keep shifting into larger pots until May, then begin to harden off by giving more air, and plant out in rich soil in June, and let them alone until the frost kills them. Of such kinds as *Ouermanni*, I have obtained splendid purple-slaked leaves, much larger than the fancy parasols, by placing a large barrowload of hot dung below the rich soil. When this hot dung system is resorted to for rather tender plants the dung becomes valuable for the surface compost in the following year.

Fine effects might be produced with these plants:—*Cannas*, *Coleus*, *Centaurea*, or *Cineraria*, either when regularly planted in belts and the ground carpeted, or in large beds when these are grouped in masses, with smaller groups of dwarfier plants, as *Amaranthus tricolor*, *Coleus*, &c., and all the open spaces covered at back with *Cineraria maritima*, and in front with yellow Ivy or yellow-leaved *Geraniums*. Splendid beds of foliage and flowers may also be made with *Ricinus* at the back, and *Cannas* and *Gladiolus* mixed all over until near the side, where a belt of *Fesine*, or *Coleus*, and *Centaurea* would make a fine termination. In fact, grant warmth, shelter, and labour power, and these fine-folaged plants would soon do away with the stiffness of our flower gardens.

29. *Solanum*.—A few of the annuals, as *Wrightii* and others, sent out by our seedsmen, are very pretty when raised in a little heat and then planted out after being hardened off to suit the open air. A group of *Solanum lycopersium* (*Fouquet*) would be attractive when in fruit, and so would smaller groups of the white and purple *S. melongena* (Egg-plant); but for ornamental foliage and rich-coloured spines, as well as large flowers, we must resort to such kinds as *Solanum marginatum*, white-edged, from Africa; *citrullifolium*, large pinnated leaves and large spines; *aculeatissimum*, good leaves and very prickly stems; *pyracantha*, with very large orange prickles and singular foliage, from Madagascar; *Balbisi*, with large leaves and whitish midribs, and white flowers, from South America, &c. All the spined kinds should have room enough and to spare, and, judging from my experience, should be plunged in their pots in moss or earth, so as to get at them with the least trouble. Except in very warm places they should be returned to a cool stove in the end of September, unless, which would be best in most cases, as they grow with great rapidity, a young stock is kept up and the older plants are allowed to perish.

30. *SPIRÆA*.—A few of these, as *Douglasii*, *Lindegana*, *fissa*, *thalictroides*, &c., may be used, and will take care of themselves.

31. *SPERMATNA AFRICANA*.—This yields fine foliage and huge corymbs of its singular flowers when planted out. It hits well, and may be kept almost dormant during the winter in a shady, cool place free from frost. It should be little excited before it is exposed in May, and planted out in June.

32. *SIACHYS LANATA*.—This woolly-leaved hardy plant would be chiefly useful for carpeting the ground in such a garden—a mode of ornamenting flower gardens that is yet in its infancy. The noble pyramidal circle I saw some time ago at Woodstock, in Ireland, would have lost a portion of their attractiveness if deprived of their carpeting of moss, as close and compact and green as we could make it here with such *Lycopods* as *Selaginella apoda*, *denticulata*, &c., under glass and shade. If ever I be privileged to see Woodstock again I hope that, under such an enthusiast as Mr. McDonald, and such encouragers of the beautiful and progressive in art as the worthy proprietors, I shall see much more of this carpeting system carried out. What I did in this way used to please me much, even when using such plants as *Verbena pulchella*, *Lobelia* of the *speciosa* section, variegated *Alyssum*, *Gnaphalium lanatum*, and the *Cerastium*s, *Sedums*, *Crassulac*, &c., with harmonising or contrasting colours, standing in little groups above the ground carpeting, and far enough apart for the beauty of all to be seen. I used to call the plan "spotted ribboning" and "raised carpeting." For instance, how beautiful a close

carpet of *Cerastium* looks, with little groups of dwarf scarlet *Geraniums* spotted over it; and then strong plants of even the beautiful *Mrs. Pollock Geranium* are not lessened in their attractions when set on a carpeting of a dense blue *Lobelia*, and a few flowers of the *Lobelia*s just peering through the foliage, as well as beneath and around the leaves.

33. *STIPA PENNATA*.—The Feather Grass is a general favourite. To make it thrive to perfection it requires frequent mowing. It is, of course, perfectly hardy. Some variegated Grasses might be introduced with propriety.

34. *SPRELETZIA REGINE*.—Several times I have had this old resident of our stoves in good order out of doors. It does best plunged and well mulched with rotten dung.

35. *TERRAZIA* would be beautiful with its masses of flowers and Sedge-like foliage. The roots might be protected with moss in winter, in addition to the withering leaves of the plant, which should not be touched.

36. *VIVIP*.—*V. major variegata* and *elegantissima* should have a place; and the green, yellow, and white variegated varieties of *minor* would be useful for edgings and carpeting the ground, especially in shady places.

37. *WIGANDIA CARYOPHYLLA*.—I never had the privilege of trying this fine plant from the *Caraccas*, but some scores of enthusiasts have told me how well it does under Mr. Gibson's management. I presume it is kept in a rather warm house in winter. In fact, the winter and spring treatment of such plants is most important, if we cannot rest them in a shed, or place them under a stage, like *Cannas*, or raise them annually from seed like *Castor-oil* plants.

38. *YUCCA*.—Who does not admire the *Adam's Needles*, with their rough picturesque attractions, in bloom and out of bloom? From *filamentosa* to *gloriosa*, through *recurvifolia*, *angustifolia*, *albifolia*, and others, they would lend their grotesque attractions to such scenery, and in ordinary winters would require no more attention than tying their leaves together by a band, that snow, or even much frozen wet, should not lodge in the heart of the plants. The tying also protects the leaves from the wind at a time when it is presumed it would try them the most.

39. *ZEA CRUENTA*.—There is a striped Japanese variety of this Indian Corn advertised. The commoner kinds make a fine appearance in a sheltered place. Most seedsmen, out of the varieties grown, can select some of robust growth for purchasers. In such a place as described we have had strong plants from 8 to 12 feet in height, with long broad leaves and with feathery crowns, besides the fruitstalks, beating out of the field all the *Arundo donax*s that were ever grown. A few of the varieties of *Holcus* should also be grown, though they are pygmies beside some of these large Indian Maizes. To have them fine sow single seeds in a hotbed in separate pots in April, repot as necessary, harden off, and plant in rich soil in the beginning of June or towards the end of May.

I thought of concluding this article to mentioning some two score kinds of plants suitable for sub-tropical out-door decoration; and amongst those occurring as worthy of being named with the others at present, I will select

40. *ACACIA ARABICANA*, the green and variegated varieties of which, if large specimens and plunged, would add much to the grotesque interest of the scene. In such a garden I would show neither pot nor tub, so that in this respect the natural should have full sway. And

41. *RHUS COPPINUS* (The Venetian Sumach), for its masses of feathery bloom, *Rhus typhina*, the Stag's-horn Sumach, and a few plants of *Ailanthus glandulosa*; the first, the Stag's-horn, for the grotesque appearance of the leafless shoots, and both it and the *Ailanthus* for the fine tropical-looking foliage. These, with common treatment, will look after themselves.

At another time I may add to what is here hinted at, as to the combinations of such plants. Meantime, as the subject seems to interest many of the readers of this Journal, I would respectfully solicit help and information to correct what is crude and to supply what is deficient in this merely pioneer article, confident that where house-room, time, and labour, and a suitable protected position can be commanded, sources of enjoyment will thus be opened up, to which even the greatest admirers of vegetable loveliness have hitherto been strangers.—R. FISH.

PROTECTION AGAINST RABBITS.—After having tried, in vain, many things strongly recommended as preventives against the gnawing of the bark of young fruit trees by rabbits, I find the

mixture of slacked lime with a strong decoction of tobacco, applied with a brush to the lower part of the stems, a most sure and reliable means of keeping the rabbits away from the trees.

—A. FOSTER in *American Gardener's Monthly*.

MONOCLETUM ENSIFERUM CULTURE.

This very fine winter-flowering plant is deserving of a place in every collection, however select. It cannot be ranked as a stove plant, for it grows too lanky in a stove heat, neither will it thrive in an ordinary greenhouse, but it requires the temperature of an intermediate-house, or from 45° to 50° in winter from fire heat.

Cuttings are to be taken from the free-growing shoots, their upper part with three or four joints and the growing point. The shoots should be about half ripe, or with their base a little hard and brown; they will, therefore, be from 3 to 4 inches in length. Cut them transversely below the lowest pair of leaves, remove these as well as those on the next joint, and insert the cuttings round the sides of a 4½-inch pot. Drain the pot to one-third of its depth with potsberds, on these place a thin layer of moss, and then fill up with a compost of sandy peat and loam, so that when the cuttings are inserted their bases may be within the least possible distance of the soil; the pot is then to be filled up with silver sand. Place this pot inside one of larger size, and so that the rims of both may be on a level. Fill the interval between the pots up to within an inch of the rim with small crocks, and the remainder of the space with silver sand. Insert the cuttings up to the lowest leaves, and not so closely as to crowd them. Give a gentle watering, and, when dry, cover them with a bell-glass resting on the sand between the pots. Place the cuttings in a mild hotbed of from 70° to 75°, shade from bright sun, and tilt the bell-glass an inch or so on one side at night, but keep it close by day. Be careful not to make the sand very wet, otherwise the cuttings will damp off, and yet it must be kept moist. The present is a good time to put in the cuttings. They will be well rooted in six weeks, and, having been hardened off by removing the bell-glass gradually, they should be potted off singly into small pots, using the same compost as for cuttings. After potting, the plants will require to be slightly shaded, and to be kept in a rather close atmosphere until established; they should then have a light and airy situation in a house, such as a greenhouse during the summer, having a temperature of from 55° to 60° at night.

When the plants fill the pots with roots, shift into 1½-inch pots, and by September, if they have grown well, they may be shifted into pots a size larger, but this will scarcely be necessary, and should not be practised later than the beginning of the month, so that the roots may take firm hold of the soil and reach the sides of the pots before dull weather set in. The soil for these pottings may consist of one-third turfy sandy peat and two-thirds turfy loam, broken and made rather fine, with the addition of one-sixth of silver sand. It is imperatively necessary to drain the pots well, for though the plant is as free in growth during the summer months as a *Fuchsia* it is by no means so easy to winter. Provision should therefore be made to keep the drainage free by placing over the crocks a thin layer of moss, or the turfy parts of the compost with the soil knocked out. In all pottings, the neck or collar of the plant should be kept slightly elevated in the centre of the pot. In winter the plants should have a position near the glass in a light airy structure having a night temperature of from 45° to 50°, and be very carefully watered.

By the following March cuttings treated as above will be sturdy compact plants in 4 or 6 inch pots, though equally good could be obtained at most nurseries for less than half the cost of making them. However, in whatever way obtained, if in 4½-inch pots they should be shifted into 6-inch ones, and if in the latter size into 8-inch pots, using a compost of sandy turfy peat one-fourth, leaf mould well reduced one-fourth, and the half turfy loam of medium texture. The pots should be of a porous nature, and well washed inside and outside. Place a rather large crock over the hole; some of less size above it; then others broken smaller still, so as to fill altogether one-fourth of the depth of the pot; an cover all a thin layer of moss or the rougher parts of the compost. This, previous to use, should be chopped rather fine, but not sifted, and mixed with a good proportion of silver sand. Having placed a little of the compost over the drainage, the pot is prepared for the plant, then turn the latter out of its pot, remove the drain-

age, and pick away the old soil from among the roots; or, if this cannot be done without injuring them, loosen the sides of the ball with a pointed piece of wood, and remove the soil from the surface down to the roots. Pot rather firmly but not very lightly, and keep the collar of the plant rather high, yet not more than half an inch or so above the surface. Give a gentle watering, and place in a temperature slightly warmer than before for a few days, or keep rather close and slightly shaded for a week or ten days until the roots are working in the new soil. The plant will be much benefited by a gentle syringing, and any shoots that grow irregularly should be stopped up to the end of June, when no further stopping should take place. The growth should be regulated by stopping and tying out the shoots so as to form an evenly balanced cone. The watering should not be at any time excessive; no water should be given until really wanted, then sufficient to show itself at the drainage; but although the plant is not to be deluged with water, it must not be allowed to suffer through the soil becoming dry. A free and sturdy growth can only be secured by the plentiful admission of air, and an abundance of light.

In June, if the pots are full of roots, shift the plants into 12-inch pots, and when the roots take hold of the fresh soil stop the shoots for the last time, for it must be remembered that the flowers are produced from their points. In August expose fully to light, and afford abundant ventilation, so as to harden the wood well, and the harder it is the better will the plants winter; their tendency to go off after blooming is a great drawback.

In September, if the plants have been grown in a warm greenhouse during the summer, or in one not very highly ventilated, nor shaded by climbers, they will be nice cones a yard or so high, and stiff and compact in growth. A cold pit would be a much better place for the plants from May to September, than any house, for then the requirements of individual plants can be better provided for, and I find that small plants do much better in small than in large, lofty houses.

Place the plants in their winter quarters by the middle or end of September, and avoid a place overhung with climbers, and the ventilation distant. Give a light and airy situation near the glass. Do not wet the foliage after this, nor preserve a close atmosphere, otherwise the leaves will become brown at the ends, and avoid watering more than can be helped—that is, give no water so long as the soil appears moist, and the plant does not show the want of it. I find the most suitable temperature to be 50°, and not less than 45°. In a higher temperature it grows, and the leaves have a sickly hue. The surface of the soil should be kept free of moss by frequent stirring, and be careful not to overwater, and then there is no danger if only the drainage be good. When in flower the plant requires more water, and also when expanding and swelling the flower-buds, but any excess at these times ends in the plant going off at the collar after flowering. It is, therefore, well to have young plants in store.

After flowering keep the plants rather dry, and do not encourage growth in winter, but cut them in early in spring, and when the growths are a few inches long repot, picking away the old soil, then shade and keep close for a few days. The shoots may be stopped up to July, but only those which are strong; the weaker ones will not require any stopping.—G. ABBEY.

QUEEN VERSUS SMOOTH-LEAVED CAYENNE PINES.

In order to prevent a wrong impression, will you allow me to offer a remark on what your able correspondent Mr. Robson has said about these two varieties of Pines in his criticism on the little work on the Pine Apple which I have recently published? He says that Smooth-leaved Cayennes are more extensively grown in Scotland than Queens; and that here and at Dalkeith, as two instances, the Queen is not so extensively grown as the Cayenne. Doubtless this conclusion has been arrived at on the part of Mr. Robson from the fact that at the time of his visit the whole of the early Queens had been fruited and used. At Dalkeith Queens are far more largely grown than any variety; and here the two varieties in question are fruited in about equal proportions, from the fact that there is most demand for ripe Pines during the London season, and from October to March. It is for winter supply that the Cayenne is so much appreciated, and of sixty Pines that will be cut here for the next three months only three will be Cayennes. I am sure Mr. Robson's well-known regard for truth and facts

will lead him to look on this correction with pleasure. He, I am sorry to say, saw our Pines under very unfavourable circumstances, for, as all who visit here annually know well, our autumn and winter Pines of 1855 were at least 30 per cent. below their usual mark, which arose from their being started without first making an early summer growth—a circumstance over which unfortunately I had no control.—D. THOMSON.

EVERGREEN SHRUBS.

At page 312 Mr. Robson invited attention to a subject which has not received generally the consideration which it deserves. I fully share in the regret there expressed, and hope that he and others will again advert to the subject; by doing so, they will at least bring under notice objects worthy of attention, and it is to be hoped that such notice may tend to promote an extended distribution and culture of shrubs not at present so well known as they should be. I shall be happy to add my mite of information to the contributions of other correspondents.

There are many beautiful plants attainable that will afford not less pleasure, and, at the same time, cost less trouble than most of those which require the protection of a glass structure; and to those who have not the luxury of a greenhouse, but wish to cultivate a taste for plants, and to seek amusement and instruction from them, there are abundant materials to repay their care. Among them evergreen, deciduous, and flowering shrubs are distinguished for their beauty, duration, and easy culture; for, after all, the greatest pleasure of the garden is to be found out of doors.

Although new plantations are being constantly made everywhere, and grounds laid out, the subjects used to ornament them exhibit a sameness that seems to ignore the existence not only of the many beautiful and interesting shrubs recently introduced, but also of some that have been long known. It is only when plantations have been superintended by persons of experience, and possessing a knowledge of what is available for adding some new and interesting feature to the shrubbery and kept grounds, that objects now too rarely seen are met with, and when met with are not always passed by unobserved. It is an additional instance of the sound judgment that has marked the proceedings of the Committee of the International Horticultural Exhibition, that by introducing classes for hardy trees and shrubs an important item of out-of-door gardening will be there represented.

I subjoin, so far as my experience goes, a short notice of the subjects of Mr. Robson's inquiry, with the addition of a few others not mentioned by him, in accordance with the expressed invitation to correspondents to record their views.

SKIMMIA JAPONICA.—I have had this shrub about five years; it appears to thrive best if peat be mixed with the common soil in which it is planted. My first plant was too much exposed to the sun's rays, which had the effect of discolouring the foliage and rendering it unsightly; upon removing it to a more shady situation it failed to produce berries, although it bloomed freely, but its growth is slow. Other plants grown in pots, and kept in a cold frame during the winter, produce berries.

DESPONTAINIA SPINOSA did well here for two years after it was planted out, it also produced bloom; it then retrograded from a cause which I was long in discovering; being placed in a favourable spot near the corner of one of my borders, I at length found to my great annoyance that a neighbour's dog had made it a special object of attention. Removal to another place is restoring it. I am inclined to think that the *Desfontainia* will do well as an out-of-door shrub, if planted in rich light soil sheltered from the north and east.

EUGENIA UONI has stood out during the last four winters; the flowers are pretty but not conspicuous; the fruit is edible, but too small and of insufficient flavour to be of service. *E. apiculata* I have not tried.

COTONEASTER SIMMONSII has retained its bright orange scarlet berries all the winter nearly up to the present time. The great drawback to this shrub is, that as soon as the berries begin to be well coloured, the leaves become shabby and fall off. The erect habit of *Cotoneaster rigida* renders it distinct from *C. microphylla*.

PERNETTYA MUCRONATA grows rapidly out of doors here, planted in a mixture of peat and common soil. Like *Skimmia japonica* it blooms freely but does not produce berries, a circumstance I am unable to account for. It is, however, a

beautiful shrub, its glossy deep-green foliage contrasting well with the reddish purple wood of the young shoots. *P. speciosa*, more compact and with smaller leaves, is also well worthy of a place.

GRISELINIA LITTORALIS proves hardy here thus far; I have had it about two years and a half. When Mr. Robson first pointed it out to me at Linton some time ago (it was a stranger to me then), I was at once convinced that it ought to be more generally known. Its habit and cheerful appearance fully justify the occasional favourable mention which Mr. Robson has made of it. It might be taken for *Majorea* Box but for the slight turn of its leaves. It is, however, quite distinct.

COLLETTIA PICTONENSIS is an interesting curiosity; its prominent triangular spines give it an appearance quite unlike any other hardy shrub. It grows well in rich light soil.

CLEANORHUS RIGIDUS will withstand any of our ordinary winters. The severe winter of 1860-61 was fatal to it here, but other plants of it have done well since. Its delicate blue flowers are very pleasing; and as it blooms freely when young, and is easily propagated by cuttings in the autumn, there appears to be no obstacle to its being more frequently met with. It is best planted in a sheltered situation, and allowed to grow freely, not trained against a wall or otherwise.

EGONYMUS JAPONICUS is a neat compact shrub, with elongate oval foliage; it looks well in winter, and thrives in almost any soil. There are two or three variegated forms of it, but neither of them so good, in my opinion, as the green kind. They are useful for variety.

BUXUS SEFFUTICOSA ELEGANS should have a place where small and compact shrubs are desirable. It should not be planted in the shade, or the markings of its foliage will be rendered less distinct. This is an evident instance of the influence of direct solar rays upon the variegation of plants. *B. balearica* is probably better known than any of the preceding; it is worthy of a passing notice.

ILEX DIFFRENA is one of the most distinct of green Hollies—but I am getting into an extensive field—this and *Ilex opaca* ought to be in every shrubbery.

It would not be difficult to extend the list. Before concluding I wish to ask for information respecting *Chamaerops Fortunei* and *C. humilis*. I have not yet ventured to give them full exposure during the winter. Has any one done so?—and how do they comport themselves? Should they prove capable of bearing our climate they will indeed be valuable acquisitions, giving quite a new feature to the garden. I should also be glad of any information respecting *Escallonia montervidensis* and *E. pterocladon*, do they approach in excellence the well-known *E. macrantha*?

Our old favourite the *Laurustinus* is found in different species. Does *Viburnum macrocephalum* form a good shrub, or rather tree? The subject of this article constitutes a wide field of inquiry, and this, if directed in a proper spirit, cannot fail to be useful and interesting.

The common *Aucubas* here are covered with bloom; as this is probably the case generally we may expect in time to hear of some fine berried specimens.—ADOLPHUS H. KENT.

ORIGIN OF THE HAGUE AND LAPSTONE KIDNEY POTATOES.

IN PERUSING THE JOURNAL OF HORTICULTURE for March 20th, my attention was drawn to an answer by your correspondent, "UPWARDS AND ONWARDS," to "D. Deal," respecting the origin of the Hague and Lapstone Kidneys. Your correspondent has been misinformed, and I beg through your Journal to inform him and the public accurately.

These Kidney Potatoes were propagated by Major Hague, but they were raised by his son Joseph, the particulars of which are as follows.

I (Joseph Hague) in the year 1827, then residing at Thorne, near Leeds, planted two pecks of Potatoes, which I had sent me from Clap Gate, near Harewood. Those Potatoes produced an extraordinary quantity of fine berries, which induced me to try to raise seedlings from them. In that I succeeded, and selecting the two best from among the quantity, I again planted the seedling tubers, but subsequently removed to Bramham, where I now reside. Having no garden connected with the house I then occupied, I took my seedlings over to Bardsey, and they were planted in my father's garden, and as he was the first to propagate them, the general impression was, and is with many people to this day, that he raised them himself; but he never

at any period of his life attempted to raise seedling Potatoes. I have five brothers, who can all testify to the accuracy of the above statement. Mr. Fuller, Florist, &c., Headingley, near Leeds, but at the time gardener to G. Lane Fox, Esq., of Bramham Park, gave the Lap-stone Kidney its name.—JOSEPH HAGY, *Bramham, near Tadcaster.*

INTERNATIONAL HORTICULTURAL EXHIBITION.

TO-DAY OPENS the grandest horticultural Exhibition ever held in this or any country; for extensive as were the kindred gatherings of Brussels and Amsterdam, and rich and varied the treasures there displayed, they each must pale in grandeur before that which has just commenced. Never before have such glorious examples of the beautiful in vegetable life been gathered together in such number, and it may be—nay, most likely will be—that those living will never have an opportunity of seeing such a display again. Let all, then, who can by any possibility visit the Exhibition, do so; for whether they be practical horticulturists or simply lovers of the beautiful in Nature, be it in form or colour, in foliage, in flower, or in fruit, they will have their tastes gratified to the full, and, we repeat, such a chance of their doing so, and on such terms, may never occur again.

In our Number for April 22nd we gave a plan of the way in which the ground is laid out; but no one can realise in imagination the effect produced upon the eye on looking upon a garden of nearly four acres of the rarest and most splendid of cultivated plants, all in the subdued light secured by the canvas roofing. The breadths of relieving shade caused by the groupings on elevated terraced beds; the avoidance of monotony by such variation of surface, by the not-excessive fragments of rockwork, and by the cascades; and the relief to the eye given by the turf facings of the terraces, must all be seen to be appreciated. The impression on entering from the Cromwell Road, when the groups of mingled flowers and foliage are first seen, and the broad walks only just sufficiently seen to awaken imagination, is most striking. Nor when the details—the groups—are examined is the first impression weakened. All is artistic, and not an interruption mars the beautiful. To the right is the Orchid-compartment, 500 feet long by 40 feet wide, heated by 3200 feet of four-inch piping, connected with one of Ormson's multitubular boilers of great power. At each end are groups, consisting of multitudes of Conifers, Taxads, and hardy shrubs; and at that near the Cromwell Road entrance Rhododendrons, Agaves, Yuccas, and other natives of the New World prevail. Then the eye encounters in the distance lofty tree Ferns, such as the *Cyathea medullaris*, one of which stands 25 feet high, Palms, Dragon Trees, lofty specimens of *Heritiera macrophylla*, *Sireltzia angusta*, and many more; whilst grouped at the sides are plants remarkable for the beauty of their foliage, relieved by others in flower, placed at conspicuous points. Those grand Azaleas, the splendid flowering specimens from the stove and greenhouse, such as are seen in no other country, the Heaths, the Pelargoniums, and a host of other floral gems, we cannot now do more than mention; but the whole constitutes a scene of beauty that the imagination may picture, but which words cannot adequately describe. Next week we shall publish a full report of the Exhibition, Banquet, and Botanical Congress.

We have much pleasure in being enabled to state that the Council of the Royal Horticultural Society, at their last meeting, passed a resolution, opening the Chiswick Gardens free to strangers during the week of the International Exhibition.

THE CÉLINE ROSE AS A STOCK.

MAY I ask your readers what is their experience of the Céline Rose as a stock for Perpetuals, &c.? I have been trying some experiments in a small way with it, and am inclined to think that in some respects it has advantages even over the Manetti. It roots quite as freely, and is inclined to throw its roots more up to the surface, and, therefore, for some soils it would have great advantages. Its roots, however, seem to spread much farther, and not to be so bushy as the Manetti; but it is far more vigorous, and quite as hardy. I should, however, like to know the experience of other cultivators. I

fancy it will be especially suited for the less vigorous class of Hybrid Bourbons, such as Louise Margottin, Modèle de Perfection, Mlle. Emma, Emotion, &c.—C. P. CREAVEN.

ROYAL HORTICULTURAL SOCIETY.

MAY 15TH.

FLORAL COMMITTEE.—Messrs. Osborn, Fulham, exhibited six very fine specimens of Heaths in full flower, also a beautiful plant of *Acrophyllum venosum*. These were awarded a special certificate. Messrs. Veitch sent some fine specimens of the double *Deutzia crenata*, *Anthurium Scherzerianum* with its brilliant scarlet spathe, and three seedling *Gloxinas*—one, Lady Cremorne, an erect white flower with deep violet markings; the great peculiarity of this plant was its tendency to produce double flowers, a second series of petals being formed towards the base of the calyx. For this variety a first-class certificate was awarded. The other two varieties were Madame Smith, a deep purple, and Lady Lyons, a deep rose.

Mr. George Scott, gardener to J. S. Gower, Esq., sent a seedling *Calceolaria*, Mrs. Scott, of the herbaceous section, bright yellow with numerous dark spots. The blooms were ill-shaped, not having the circular outline so essential in this gay and attractive flower. From Mr. Keeler, gardener to J. Todd, Esq., came a seedling *Zonale Pelargonium*, Rose of Dulwich, very far behind this class of flowers; and from Mr. Herr, Hammersmith, seedling *Zonale Pelargonium* Lady Smart, of the marbled section, but of no merit. Mr. Bull, Chelsea, sent *Castanea vesca marginata*, an old and well-known plant, and *Picea-nia tabula-formis* in flower. The Rev. George Cheere, Papworth Hall, exhibited six well-grown specimens of the large-flowering variety of *Mignonette*. These plants were grown in No. 48-pots, and were considered a great success in good cultivation. A special certificate was awarded them. From the same gentleman came also a seedling *Tropaeolum* called Papworth Scarlet, with very brilliant deep scarlet flowers. Messrs. Cutbush sent four pots of *Myosotis intermedia*, both the blue and white varieties; James Bat-man, Esq., cut specimens of *Dendrobium Devonianum*, *Urochloa Lindenii*, and an *Acerides*, producing its flower-spire from the extreme point of the shoot of the plant; and the Rev. M. J. Berkeley, a cut specimen of a seedling *Rhododendron*, with white flowers, deeply spotted, probably a sport from *guttatum pictum*.

From the Society's gardens came a very fine specimen of *Rhododendron Nuttallii*, covered with a profusion of blooms, to which a special certificate was awarded. *Epidendrum aromaticum*, *Cyrtocidium filipes*, six plants of the new variegated *Zea caracana*, or variegated Indian Corn, which, if it retain its variegation, will prove a very useful and ornamental decorative plant for the borders; a *Lilac*, called Dr. Lindley, very similar to the cut specimens of Charles X., which were brought from Chiswick; the clusters of flowers are very large, and conspicuous from the dark colour of the unexpanded buds. A large collection of small well-grown plants of variegated *Zonale Pelargoniums* from the Society's garden at Chiswick, consisting of Mrs. Pollock, Sun-t, Gaiety, Beauty of Oulton, General Longfellow, and many others, were much commended for their extremely healthy condition and good cultivation. Mr. Proctor, Clifton, exhibited a curious specimen of a Holly branch, which had assumed the stag's horn or branching form of flattened shoots, and which the common Ash tree and others are subject to.

Owing to the very cold weather many plants intended to be sent for exhibition were kept back, and the necessary preparation for the great International Exhibition next week most probably deprived the meeting of very many interesting subjects. It is most gratifying to observe how well these Tuesday meetings are kept up, and how much interest is displayed by the attendance of so many Fellows, whose thanks are due to those exhibitors who so liberally furnish plants for these meetings.

FRUIT COMMITTEE.—The only subjects exhibited were a brace of Champion of the World Cucumbers by Messrs. A. Henderson & Co., and several Citrons by Mr. Scott, of Knaith Hall.

FORTNIGHTLY MEETING.—His Grace the Duke of Buccleuch, K.G., the President, in the chair. The awards having been announced, and eighteen new members elected, the Rev. M. J. Berkeley remarked that the plant shown as *Psychotria macrocephala* at the meeting of April 17th, though figured by M. Lemaire under that name, proved to be *Rudgea macrophylla* of Benth. A *Rhododendron* shown by Mr. Johnson was then stated to be nearly allied to *Keiskei*, of which the flowers bear considerable resemblance to those of a *Thibaudia*, and one sent by Mr. Lascombe to the last meeting, to be merely a form of *R. niveum*. It was also mentioned that several of the blooms of the fine example of *Rhododendron Nuttallii*, which came from the Society's garden, had been fertilised with the pollen of other kinds. The *Morrel* exhibited at the meeting of May 1st had on further examination proved to be *Morchella crassipes*, a species larger than the common *Morrel* but of inferior merit, for though it may be used when young, it soon decomposes. Attention was then directed to a cut specimen of *Acerides Warneri*, flowering in an abnormal manner; and Mr. Bateman stated in a letter that *Jonesia asoca* is now coming finely into flower at Chatsworth, and he hoped to be able to produce it at the next

fornightly meeting. Mr. Berkeley having remarked that *Brownea grandiceps*, which he had once seen in flower in Wiltshire, is quite as handsome as the *Jonesia*, passed on to *Gloxinia Lady Cremorne* exhibited by Messrs. Vetch, which might be compared to the *Hose-in-Hose Primula* in appearance, but differed from it in not having a coloured calyx like the corolla, but a corolla in two separate divisions occupying the same relative positions as the two divisions in *hose-in-hose* flowers. *Lilacs Charles X.* and *Dr. Lindley* then came under notice, and the former was described as being by many degrees the finer; also the *Long-podded Radish*, the *Raphanus caudatus* of Linnæus. There are, it was stated, two perfectly distinct varieties—one the *Rat-tailed Radish* of Madras, the other that sent out by Mr. Ball, of which the pods attain a much greater length. A branch of *Holly* sent by Mr. Procter, of Clifton, was the next object of attention. It was in that peculiar state known as fasciated, which is very common in *A. paraguay*, and arises from several stems becoming united or grafted together during their growth. The efficacy of sulphur as a remedy for the *Hop-mildew* was then touched upon, and although a prejudice had existed among cultivators against its use, and the *Hop-factors* had by their refusal to purchase *Hops* from grounds where sulphur was employed prevented those willing to use it from doing so, the factors were now convinced that it exercised no prejudicial effect on the quality of the beer, and Mr. Berkeley added he was happy to hear that they had withdrawn their opposition.

PEACHES AND PEARS IN NEW ZEALAND.

We have received from Mr. Swale, of the Avonside Botanical Gardens, a dozen of Royal George Peaches grown by him. They are of very large size and weight, and fully equal to any grown in England. These specimens show what can be done here for the cultivation of the Peach. The soil and climate of New Zealand are admirably adapted for this purpose, and it is a subject of regret that gardeners do not pay more attention to the culture of this fruit. The bright sunshine we enjoy here is eminently favourable to their growth. The gardeners and amateurs, in too many instances, are satisfied with Peaches, the ordinary production of the ground. Now, the climate is almost similar to their natural habitat, Persia, and with a little care and attention it is possible to raise Peaches equal to those grown on walls in England. The chief requisites are to thin out the crop, and by judicious pruning to admit a free circulation of light among the trees.—*Lyttelton Times, Feb. 23rd.*

[NOTE FROM THE GROWER.—One dozen of these Royal George Peaches weighed 4½ lbs. good weight, and in circumference the average size of the Peaches was 8½ inches. In this instance I may mention a Windsor Pear tree, about six years old, which produced me in this unfavourable season with us for Pears a crop weighing nearly 2 cwt. (within 4 lbs.), of good-sized fruit, a register being kept of the weight each time any were picked for sale. The crop of Windsor Pears does not ripen here all at one time. They are in great demand at 1s. per pound.—W. S.]

ENTOMOLOGICAL SOCIETY'S MEETINGS.

THE APRIL MEETING was presided over by the new President, Sir John Lubbock, Bart. Amongst the donations to the library were the publications of the Royal Society, a monograph of the *Platypedes*, by M. Chapuis, &c.

Mr. W. W. Saunders exhibited a remarkable group of eggs of some unknown insect (most probably a species of *Hemiteobidae*), from Australia, affixed in a row on the bark of a tree by slender peduncles, which were alternately directed in opposite angles; the eggs also, which are oblong, being alternately placed longitudinally and transversely. Also, the larvæ of a Beetle, probably belonging to the *Lamellicorn* tribe, which exhibited an elongated fungus of the genus *Sphaeria*, growing out of each side of the neck like a ram's horn. Also, four larvæ of a species of *Locust*, from Australia, about half an inch long, attached to a twig; one of them was tightly held head downwards by the other three, which were themselves so locked in a close embrace, and had their legs so intricately entangled, that it seemed as if they had been unable to extricate themselves and thus had died.

Mr. Rogers sent for exhibition specimens of *Pimpla oculatoria*, one of the *Ichneumonidae*, which he had reared from the egg-bag of a Spider found under the loose bark of an Oak fence. The species had previously been reared on several occasions from Bramble sticks, which had been bored into by other insects in order to build their nests therein.

Mr. F. Smith exhibited a specimen of *Bembex olivacea*, which was stated to have been taken many years ago by Dr. Hicks, near Gloucester. It had been figured by Donovan as British, under the name of *B. octo-punctata*, but as no locality had been recorded, it had been subsequently doubted whether it is a truly British species.

Mr. J. J. Weir exhibited some larvæ supposed to be the common Mealworm, which had been found in a wine-cellar, where they had done considerable damage by eating through the corks of port wine

bottles, so that the wine had escaped, the sealing-wax with which the corks had been capped not having proved a preventive against their entrance into them. They had only partially attacked the corks of sherry bottles, which had consequently escaped, probably in consequence of the flavour imparted to the cork by the wine not proving palatable to the larvæ. It was suggested, as a probable cause for their incursion into the cellar, that bran might have been used in packing the wine instead of sawdust.

Mr. W. W. Saunders said that numerous instances of the injury done to wine corks by various insects had been brought before the Society. He remembered a case in which a number of larvæ of *Dermestes lardarius* (which had been brought into the Docks with a cargo of skins), made an incursion into a neighbouring warehouse, in which were stored some manufactured corks, which they perforated and rendered useless. Large damages were claimed against the Dock Company, and a lawsuit seemed imminent, but the matter was finally compromised.

THE MAY MEETING of the Society was held on the 7th inst., the chair being occupied by W. Wilson Saunders, Esq., F.R.S., &c., Vice-President. The donations to the library received since the last meeting were very numerous, including the publications of the Royal, Linnæan, and Royal Agricultural Societies, the Entomological Societies of the Netherlands and Stettin, and an extensive series of entomological works presented by the Secretary, J. W. Denning, Esq.

Mr. McLachlan exhibited some galls found on Ground Ivy at Lewisham, supposed to be those produced by *Aylax Glehonia*, which, however, occur singly, whereas those now found formed a cluster of four.

Mr. Bond exhibited a fine variety of *Cabera exanthemaria*, reared by the Rev. M. Horton.

Mr. Newman exhibited some larvæ of *Hepialus lupulinus*, destroyed by a fungus (*Sphaeria*?), which occupied the whole of the interior of their bodies, sending out its mycelia in all directions through the skin, whilst in some specimens a stout capitate column rises from the neck of the larvæ immediately behind the head, evidently the fructification of the fungus. This curious formation is well figured in the "Entomologist" for the present month.

Mr. Stainton exhibited some Dipterous larvæ, sent from Alloa by Mr. Berthwick, which had entirely destroyed the main stems of young Wheat plants in that neighbourhood.

Mr. Saunders, however, stated that the habits of this insect had been previously well observed, and that its result was the throwing out of an abundant supply of lateral stems, no more injury being done to the crop than by pasturing sheep upon Wheat when growing too luxuriantly at the beginning of the season.

Mr. Stainton also exhibited a number of drawings of the larvæ of various species of *Microlepidoptera*, made by Miss Wing, from specimens which he had collected at Mentone and Cannes, amongst which was *Prays oleella*, which is as injurious to the young shoots of the Olive as *P. curtisellus* is to those of the Ash; also, a drawing of a true gall formed on the shoots of *Gypsophila saxifraga* by a small *Lepidopterous* larvæ (*Gelechia* sp.?). The only other instance hitherto observed of a true gall formed by a *Lepidopterous* larvæ is that produced upon *Polygonum aviculare* by *Asychmia aratilla*. He also exhibited a drawing of another larvæ (*Gelechia* sp.?), which he had found feeding on the bark of the Spindle Tree, beneath masses of excrement of *Yponomeuta corymella*.

Mr. Janson exhibited specimens of *Throsens clateroides*, a species of small Beetle, new to Britain, taken by Messrs. Brewer and E. Smith, near Rochester.

The Chairman exhibited some interesting nests of Spiders and *Oiketicæ*, from Australia; and

Mr. E. L. Layard gave an account of the manner in which the caterpillars of the last-named genus (also found at the Cape of Good Hope, Ceylon, &c.), construct and enlarge the curious sack-like cases in which they reside.

Mr. Howard sent a small collection of insects of various orders, from Port Natal.

Mr. Layard called the attention of the Society to the fearful ravages of a small species of White Ant at St. Helena, which had been introduced into the island about twenty years ago from the west coast of Africa, and which threatened to destroy every portion of timber-work in the island. Already James Town may be said to be devastated by it. The Cathedral was entirely destroyed, as was also the Library and its contents. Teak is the only kind of wood they will not eat, although they freely bore through it. He also gave an account of the habits of Honey Bees at the Cape of Good Hope, where, although they sometimes took up their abodes in caverns, &c., where they had abundance of space, they swarmed as often as our domestic Bees confined in hives, and that, too, notwithstanding various means had been tried, including the use of Nutt's hives, without any satisfactory result in preventing the swarming.

The following papers were read:—"Notes on Collecting *Lepidopterous* Insects during the Spring of 1866 at Hyères," by the Rev. Douglas Timmins, M.A. "Descriptions of New British *Ichneumonidae*," by Mr. Thomas Desvignes, in which nearly thirty new species belonging to *Gravenhorst's* genus *Tryphon* were described.

The Chairman announced that the part of the Society's "Transactions" containing Dr. Wallace's prize essay on the culture of the *Ailanthus* Silk Moth, was ready for distribution among the members.

HEATING BY GAS.

DURING a conversation relative to the modes of heating applicable to garden structures, one of the Editors of this Journal stated as his opinion that "there is no mode either more effective or attended by so small an amount of trouble as heating by gas." He qualified his opinion afterwards by reminding his auditors that he was talking to amateurs who managed their own small greenhouses and conservatories. He was asked to furnish a plan, and he endeavoured to escape by referring to the back volumes of this Journal. That, however, was not considered satisfactory, and eventually he promised that, if he thought it would be useful, he would gather together the statements and illustrations scattered through the volumes to which he had referred.

For the use of new subscribers he had arrived at an affirmative conclusion, when a letter from a correspondent, "J. P., Northampton," inquiring how he could best exclude frost from a small conservatory, now erecting, prompted to the speedy publication of what follows.

The simplest mode is using a gas stove. We have employed such a stove, merely to exclude frost from a greenhouse, and it answered very well. It was a small circular stove, with one Argand burner, and an iron tube instead of glass round the burner. An iron chimney carried off all the noxious gases.

A modification of this is the following:—

Fig. 1.

This apparatus (*fig. 1*), consists of a burner, *a*—a ring of brass tube—5½ inches in diameter, pierced with fifteen small holes, placed 4 inches above the level of the floor. Over the burner is what may be described as an inverted galvanized iron trough, 9 inches wide, 7 inches deep, and 5 feet long, resting on four legs 4 inches high. The burner is placed under one extremity of this trough; from the other end runs the chimney, which is of three-inch galvanized iron piping, the joints of which are not cemented. This rises 5 feet, and is then carried across the house 12 feet, and finally makes its exit in the kitchen chimney. It must either be carried into a chimney, or, if this is not possible, it should, after being carried across the house, rise 5 or 6 feet perpendicularly. Placed on the top of the trough over the burner is an evaporating-pan, *b*, containing about three gallons.

This arrangement, if not ornamental, is cheap and useful, and, with a little expense, may be made more elegant; at any rate, it is entirely removed during the season when the more attractive flowers of summer invite visitors.

The house is a lean-to, 14 feet square, and 13 feet high at the back.

If hot water is employed to diffuse the heat, then the amateur has the following modes to select from. The laudations of each are the inventors', not ours.

The greatest advantages the following mode (*figs. 2 and 3*), offers are the facts that it requires no expensive brick fixing, that it can easily be moved and adapted to another greenhouse in case of removal; it is clean, can be set in action in a moment, and is easily regulated even by a lady, and, where

there is gas, may be kept for any time at a comparatively small cost, when the great expense and trouble of the old mode is considered. There is no risk with gas of losing your plants in consequence of the fires going out, and no time lost in attending to them.

Fig. 2 is a sectional view of an apparatus in a cellar, from which the pipes are led to the greenhouse. *A* is the boiler, composed of two galvanised iron bowls, which may be bought

Fig. 2.

Fig. 3.

Fig. 2. Sectional view.
Fig. 3. Inner tube, kept in centre by stays.

for 1s. 6d. each, and which are soldered together an inch apart by means of a circular ring of No. 11 zinc. *B* is a flow-pipe, with *c*, a small tube (an inch clear), running through a good part of its length, and communicating as a chimney with the hot-air chamber *F*. *C*, Return pipe, galvanised iron, 3 inches in diameter, and connected to boiler. *E*, Ring-burner to be bought for 1s. 3d. *H*, Circular tube of sheet iron, same size as outer edge of boiler, and made to take away. There must be a small swing-door for lighting gas. *I* Are holes at bottom for the admission of air. *J*, Stay from one pipe to another. *K*, Union joints. These union joints can be in any part of the return-pipe, but can only be beyond the chimney on the flow-pipe. As a matter of course, the farther this inner tube goes through the flow-pipe, the greater afterwards is the facility for heating rapidly. For some time after heating there can be no heat felt issuing from the tube *c*, proving that the cold water is abstracting all the heat. When the water becomes heated then the warm air escapes; but, by lowering the burner, and a little attention at first to test its capacity, the loss of heat can be brought very low.

Fig. 3 is a section of the flow-pipe, showing how the inch tube is retained by stays in its place within it.

One advantage, and it is especially an advantage in a small structure, arises from the whole of a gas-heating apparatus being removable when no longer required. If there is a tap close to the wall on the gas supply-pipe, and the pipe attached to the gas-burner is connected with that tap by a galvanised indian-rubber joint, then the tap may turn off the supply of gas, and the stove, boiler, &c., be disconnected from it and removed at any time.

A correspondent states that for the last three years he has

used indian-rubber tubing alone, for jointing both hot-water and gas-pipes. After a severe test, it answers the purpose admirably.

A piece of galvanised indian-rubber tube, of a somewhat larger diameter than the pipes to be joined, is passed over the end of each. The vulcanised tubing is then encircled with stout string (S), at a distance of half an inch from the termination of either pipe, and tied up strongly and neatly. The junction presents the appearance represented in *fig. 4*. Though

Fig. 4.

so simple, this is a most effectual joint. Taps can be inserted in a similar manner.

The next (*fig. 5*), is in a greenhouse, span-roofed, with glass on all sides, and which is small, being only 12 feet square.

From the outside is laid a wooden box, 10 inches by 5, opening under the gas-burner.

To prevent any smell at lighting there should be a continuation of pipe beyond the burners, opening externally. Letting the gas escape from this for a minute ensures the pipes being

Fig. 5.

Wooden trunk for admission of air.

- A. The boiler.
- B. Chimney of two-inch screwed gas-pipe leading through the water.
- C. Steam safety-pipe opening externally, being of one-quarter-inch pewter-pipe.
- D. To supply water, kept close.
- E. Two gas-burners in rings. One has been sufficient at present.
- F. The door to pass in a light. This is a brass screw plug. Such can be bought at any brassfounder's. The centre has been cut out, and a small piece of tile inserted, as it is satisfactory to see the light. The door has a cross handle.
- G. Is a circular addition to the boiler, and ought to have at least 6 inches of ground round the bottom.

full of gas, and, consequently, it is quickly lighted. This addition is important, as mixed air and gas might puff out in the face, besides vitiating the atmosphere of the house. The boiler, &c., is all of copper, except the chimney, which is gas-pipe, and cost altogether about 70s. Three-quarter-inch pipe is recommended, as after midnight the pressure is only small, although quite sufficient. The apparatus is placed under a stage, and when not in use hidden by a pot of Ivy flat-trained on purpose.

Lastly, there is the following (*fig. 6*), patented by Mr. Clarke, Eagle Foundry, Liverpool. In this the boiler is formed of seven tubes, with a ring of jets of gas beneath. There are seven small burners, one fixed exactly under the centre of each tube. The boiler is made of copper, and is 12 inches high by 9 inches in diameter; and the water-space is between the tubes upon the same principle as in the locomotive engines. The whole is enclosed in a sheet-iron case just the shape of the boiler, made to fix on the top, and extending down the side nearly to the bottom. This case confines the heat to the outside of the boiler, and to prevent the cold air getting between this casing and the boiler a flange is fixed.

In the above drawing, *AA* are two cast-iron boxes about 9 inches long, and of just sufficient width and depth to admit of an inch-bore pipe being screwed into them. The top one, of course, forms the flow, and the bottom one the return. *B* is another box which answers for the return; *c* is a small airtube; *D* the supply-cistern, which may be placed wherever most convenient so long as it is above the highest point of the pipes, which should be the box *B*; and *E* is where the supply-pipe, which need not be more than three-eighths of an inch thick, is generally put in.

There are four flows and four returns, the surface of which is a little more than two rows of four-inch-bore pipes; for the circumference of a four-inch-bore pipe is about 14½ inches, while that of four one-inch-bore pipes is better than 16 inches. Sometimes only three rows are used, and sometimes only two, according to the size of the house. *F* is a slide for lighting the gas, which can be opened and shut at pleasure. There is a tap for drawing the water off at any time. *H* is a two-inch sheet-iron tube for carrying off the burnt gas.

This boiler may stand in the greenhouse and the fine-pipe be taken through the roof, or, what is better, if practicable, put into a chimney-shaft. This boiler contains about three quarts of water.

Neither two nor three-inch pipes ought to be used for gas, if economy is to be considered. Supposing, for example, the circumference of a three-inch pipe is 9 inches, 1 foot in length would contain 81.82 cubic inches of water. Now, if we use three one-inch pipes instead of one three-inch pipe, we obtain the same heating surface, and have only 28.27 cubic inches of water to heat; consequently a great saving in gas is effected. With this gas boiler one-inch bore wrought-iron pipes are used, and the frost is kept out of a greenhouse 20 feet long by 15 feet wide for something like 3s. 6d. or 4s. per week.

Fig. 6.

THE MANGOSTEEN.

"AGAIN [at Singapore] I tasted the Mangosteen; and I now boldly record my opinion that this much-vaunted fruit is inferior even to a Banana, and not to be compared with the Mango."—*Mutcr's Travels*, vol. ii., p. 181.

I have often closely questioned a naval friend, who has eaten

this fruit at Penang, a place in which alone it is said to be quite perfect. He always talks about it in a sort of rapturous way; but when I have given him a very fine well-ripened Nectarine, and have said, "Well, what do you now say about the Mangosteen?" he has paused and said, "This is quite as fine;

and if the weather were as hot as at Penang I should, as the Chinese say, kick up a bobby about it, equal to what we do at Penang about the Mangosteen."—T. R.

PROFIT FROM FORCING PEACHES.

The erection of orchard-houses has now become so general, that a word in favour of their adoption would be unnecessary; but any facts which tend to illustrate their value must prove acceptable to all interested in the cultivation of fruit trees.

The rapid mode of transport which has originated within the last quarter of a century, has brought easily within our reach the productions of the gardens of our foreign neighbours, and in many cases within a few hours of such being gathered and packed; yet with all these advantages I am inclined to assert that the produce furnished by the forcing-houses and gardens of Great Britain has not decreased in value by reason of such competition.

The following facts will, I think, prove this; and similar evidence I believe is often obtained under similar circumstances, but passes unrecorded. If a debtor and creditor account of the marketable value of the produce were kept, it would afford evidence that the cultivation of fruit trees under glass is anything but unprofitable; though it is in many instances difficult to convince the grower to the contrary.

But to proceed. In a lean-to house, 38 feet by 16, we have here planted near the centre—that is, within the fourth of the distance of each end of the house, one Royal George Peach tree and one Nectarine. The two occupy the whole area of the house. The growth of the former exceeds the latter by one-fourth. The Peach tree has been planted twelve years. It was removed from the garden wall, against which it had been for some years previous to its removal. Every precaution has been taken to confine the roots to the border prepared for them inside the house, so that they may be entirely subjected to the heated air. The house is heated by means of three rows of four-inch pipes, one flow in front, and two return midway. The trees have been under my care since the autumn of 1861; and as we annually dispose of the fruit, of course a faithful account is kept of the sums obtained. That your readers may form a somewhat accurate idea of the value realised I here subjoin the details.

Year.				Sum received.		
				£	s.	d.
1862	Ripe June 15th Peaches 421 dozen 42	10	0
1863	Ripe May 25th " 48 dozen 48	10	0
1864	Ripe May 1st " 42 dozen 67	0	0
1865	Ripe April 21st " 27 dozen 65	0	0
1866	Ripe May 10th " 38 dozen 50	0	0

The Nectarines yield annually about twenty dozen, and the sums obtained average about 15s. per dozen.

In deducting the expenses of labour and fuel, it should be considered that the house is but one of a range in which Grapes are forced, and that the whole of the compartments are heated by one of Weeks's No. 4 tubular boilers.—MICHAEL DAVIS, *Gardener, Rockampton Park.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

DURING showery weather, such as we have lately experienced, it is difficult to keep down effectually the seedling weeds; no sooner does the bright sunshine tempt one to cut them up than down comes a shower, and starts many of them into renewed activity. To remedy this it is advisable, after hoeing through such crops as Onions, Carrots, Parsnips, &c., to choose a fine day soon afterwards, and go over the whole with a long-toothed iron rake. The disturbance is generally effectual in killing the weeds, and is, moreover, of great benefit to the crops by scarifying the surface, and throwing it open to receive the full benefit of atmospheric influences. In deep, retentive, and cold soils it is advisable, in order to attain anything like success, to forward early crops by artificial means, and transplant. This practice is very essential, whatever the nature of the soil may be. One general effect of transplanting is to give the plants a check, which throws them sooner into bearing; at the same time, if the ground is in good condition, and well trenched, they are as productive as if sown in the open ground. Beans, make another sowing of Longpod if they are much in request, and take off the tops of those in blossom. Broccoli, make another sowing of Miller's Dwarf White Russian, these will come into bearing in the end of April and beginning of May.

Prick-out the Cape Broccoli and Cauliflowers, and keep all seedling crops of this kind well dusted with quicklime, otherwise you will have to repine over the loss of most of them from snails and slugs. Dwarf Kidney Beans, sow the dwarf sorts for success on, also Scarlet Runners, and transplant those which have been forwarded, if not already done. Sow also Jerusalem Kale, and the old English Colewort, both are very useful for planting after Potatoes. Peas, sow in smaller quantities for a succession; the north side of sloping banks is well adapted for these sowings, being generally cooler and more retentive of moisture. Keep the surface well loosened amongst Peas just coming up, and earth-up and stake others as they become ready. Spinach, keep up successions. Turnips, sow another good breadth, and thin-out those advancing; endeavour to keep them in a healthy growing state, which is one of the best preventives against the early-sown ones running to seed.

FRUIT GARDEN.

Peach and Nectarine trees infested with green fly, and having curled or blistered leaves, should be well syringed with strong lime water from a garden engine. Continue to nail-in the young shoots of all kinds of fruit trees as they become sufficiently advanced, and keep the finger and thumb at work amongst superfluous shoots. Give the Strawberry-beds a final stirring, and have some available material at hand for laying about the plants, to prevent the fruit from becoming dirty. Keep a number of figure-4 traps constantly set about the beds, as there are no greater destroyers of Strawberries than mice.

FLOWER GARDEN.

Recently-transplanted trees and shrubs must be carefully attended to with water until fairly established. It is frequently the case, however, that too much water is given at the root, thereby softening the soil, and rendering it ungenial to the young rootlets and the after-growth of the plants. The soil should be kept moist, but not to the extent of saturation, and the plants should be watered overhead with the engine on the evenings of bright days, which will be of more service in repairing the loss sustained by evaporation than if given in excess to the soil while there is a deficiency of active rootlets to absorb it. When Roses are infested with the grub, it will be necessary to go over the plants frequently to destroy this pest. Green fly is also sometimes very troublesome at this season; a good washing with the garden engine on two or three successive evenings will greatly assist in exterminating it. With the wind east, and a fair prospect of a sharp frost any night, there is no great inducement to commence bedding-out in earnest. It is to be hoped, however, that we shall have experienced a favourable change before the appearance of this notice, and that the planting of all properly-prepared stock may be proceeding under favourable auspices. Begin with Calceolarias, Verbenas, and Scarlet Geraniums, leaving Heliotropes, Lantanas, Anagallis, and such things as are easily injured by frost, until planting the more hardy shall have been completed. Branches of evergreens are easily enough obtained in most places, and a sprinkling of these stuck into the beds after planting will be of great service in protecting the plants from the drying effects of bright sunshine, and will also ward off a degree of frost which to unprotected plants would be destructive. All shoots which are long enough to be injured through being blown about by the wind, should be pegged down immediately on planting out, and a good watering should be given to settle the soil about the roots. This, however, will be better done early in the morning, if there is any reason to fear frost. Auriculas should now be placed on a north border, the seed will ripen there very well; if the pots are well drained, and placed on a layer of ashes to prevent the ingress of worms, the plants will sustain no injury from exposure. Polyantheses require more shading than the Auricula, otherwise they are liable to the attacks of red spider. Carnations and Picotees are growing fast, so are weeds, which must be taken from the pots as they appear. Cut over those which are spindling without showing increase. Do not delay putting down the sticks to which they are to be attached. Pansies may be shaded, and not too many pods of seed allowed to ripen. Tie up Pinks as they spindle.

GREENHOUSE AND CONSERVATORY.

Some of the earlier-flowering New Holland and other greenhouse plants will soon be past their best, and a judicious amount of foresight and care will be necessary to avoid being short of specimens in bloom with which to supply their places. Many subjects in the stove, as Achimenes, Gloxinias, &c., should now be in a forward state, but these must be carefully prepared for removal to the cooler and drier atmosphere of the

conservatory, otherwise there will be great risk of injuring the foliage, &c. When circumstances will admit, plants that have grown in a moist, warm atmosphere should be removed to an intermediate-house about a fortnight previous to their being taken to the conservatory. Clerodendrons, Allamandas, &c., will continue growing slowly and blooming for three months at a time, whereas if this is neglected, their beauty may be very short-lived. Aim at maintaining an even temperature in the conservatory after removing plants thence that have grown in the stove, and furnish a little shade on bright sunny days; also, see that every plant is perfectly clean before placing it in this house, and that the creepers, &c., are not infested with insects. To the last named class of plants should be added the charming Bougainvillea, and the beautiful Lapageria rosea. For the former the warmest part of the house should be selected, and if possible its roots should have a little artificial heat. Young stock in pits will now be making rapid growth, and must be carefully attended to as to watering, stopping, training, &c. Examine plants frequently for mildew, and apply sulphur the moment it is perceived, some of the softwooded varieties being very liable to be attacked by that pest at this season.

STOVE.

The plants here will be growing very freely, and will require frequent attention as to training, stopping, &c. Keep them properly supplied with pot-room, and afford them all the sunshine that they will bear without scorching, with a moist atmosphere, admitting air on mild days. Go over creepers frequently, so as to direct their growth, and prevent their becoming entangled, which without attention will soon be the case. Syringe and shut up early in the afternoon of bright days, and be as sparing as possible of artificial heat. Afford *Osculids* in growth a thoroughly moist atmosphere, giving them a good steaming every bright afternoon, by syringing and shutting up early. Admit air in moderate quantities on mild soft days, but carefully avoid currents of drying winds. Examine the plants individually every other day, and water such as require it, but be careful not to give too much to those starting into growth, and a cool atmosphere will greatly assist in prolonging the beauty of those in bloom.—W. KNAPP.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Took the opportunity of the dry days to run the Dutch hoe among all growing crops, as Cabbages, Cauliflower, Onions, and Potatoes. Pricked-out Lettuces, Cauliflowers, &c., and planted beds of Mint and other herbs, as these little matters are often of more consequence than greater things. A celebrated gardener told us that the greatest annoyance he ever endured was to be almost without Parsley, and that season, do what he would, it would not grow, and he only succeeded at last by raising it in boxes, and transplanting it into fresh soil obtained from the sides of the highway. We have heard often enough of land being Clover-sick, but never before of ground being Parsley-sick. Ever afterwards our friend turned his soil intended for Parsley deeply, in order that there might be fresh soil for it to root in. Previously the Parsley flourished well enough at first, but then the roots would all rot and damp away without any apparent cause.

Fresh soil may remedy the evil complained of by our correspondent "VEXED." What seems to vex him chiefly is the supposed fact that Parsley is so much more in demand now than that he is short of it. We say supposed, as it may only be a supposition, because, though there is a natural tendency in us to value most that which is scarcest, there is also a tendency to think that people are taking advantage of our deficiency, when really they are only taking the usual supply. However, in all such matters it is generally sound policy to say as little as possible of being short of anything, as that may give it a value to the consumer which it never had before. On the other hand, the best things will pall on the appetite if presented too often. Only give a lady Kidney Beans every day in December, and they will come to be no more valued than they would be in August.

Dwarf Kidney Beans.—Sowed out of doors in rows 2 feet apart; turned a lot out of four-inch into ten-inch pots, and set them in the front of an orchard-house. Thinned those standing behind the standard trees in the orchard-house, as they were rather too cool and shaded to open their bloom so fast as we wanted. By moving one half to a pit we set the rest in the

open spaces, and they will thus form successions. Those early fruiting ones that, after bearing heavily, had been cut back and planted out in an earth-pit with a little protection, are breaking and showing well, so that at farthest there will only be a few days when we cannot gather. We might have continued with a bed of Newington Wonder, but this small kind is not so good for late as for early forcing, as the Beans are apt to form so quickly even in young pods. We wanted the room very much for Strawberries, and as the leaves were becoming a little shabby from frequent pruning, we pulled them out, and prepared the place for Strawberries, which see.

Potatoes.—We still have a few to plant. Gave plenty of light and air to those under protection. Dug up some beds that have been exposed for some time, and brought back frames again to be placed over Strawberries, lifted and planted out in the soil in which the Potatoes grew. We allude to the matter chiefly to chronicle how well the Potatoes in seven-inch and twelve-inch pots did this season. We have found, after several years' experience, that much more produce in the same room may be obtained from pots than from planting in a pit and frame in the usual way. In the smaller pots we generally put one set, and mostly obtained from six to eight good-sized Potatoes, and from the larger pots nearly as much in proportion. Besides, the pots could be moved from place to place, a matter of importance where there is little room under glass. We used also to be fortunate when placing a set in a four or five-inch pot, and when the stem was 6 inches high, plunging the pot and 2 or 3 inches of the stem in leaf mould. The Potatoes then lay generally on a level with the surface of the pot, and without the plunging the new Potatoes would have been greened. Counting glass light for light, and under pretty similar conditions as respects artificial heat, we obtained fully one-third more produce from those in pots, and when the pots are not large the Potatoes may be fingered to obtain a few of the best, with less injury to those remaining than when planted out in beds.

Cucumbers.—Pruned severely the earliest three lights that bore heavily, to give them a chance of fresh growth, and if they do not come strong will replace with plants now rooting from cuttings. Volunteer we consider one of the best Cucumbers to bear of the rather smooth-skinned kinds. Telegraph is also very good, and grows longer. Conqueror of the West has a nice bloom for those who wish the Cucumber to appear whole on the table. Ayres's Perfection, a small variety of the Kenyon or Lion House race, is a fine bearer, and useful for those who want a small fresh Cucumber every day. It is generally very crisp and sweet, when 1 inch, or rather three quarters of an inch in diameter, and 6 or 7 inches long. In front of those in frames, we have applied a lining chiefly of mown grass after it had lain to heat, taking care that no fumes from it should find their way inside the frames. This would not have been wanted but for two circumstances: The beds originally, from shortness of material, were made shallow, and the heavy rains running down the glass had soaked into the front and cooled the beds there. We used to prevent this by one of two simple modes, and we have been going to do it every day: but though a small job, every day brought so much work, that it is not done yet. The simplest mode is to have boards 1 inch thick, and from 9 to 12 inches wide, to place in a slanting position in front of the frame, so as to catch all the rain that comes from the glass, and throw it all that farther away from the bed. This is a very quick and simple mode, where you can be fortunate enough to lay your hands on the boards, and this we could not manage. The boards will be sure to warp in such a position if let alone; but they will be serviceable for this purpose for a long time, if the person who uncovers or looks after the frames would just turn the boards upside down every second day or so, which, notwithstanding sun and weather, would keep them straight and level. Such boards placed close to the frame would also be so far a safeguard against steam rising and penetrating into the frame from the linings. Wherever linings are used, and these are not wrought sweet previously, which we never could think of, care must be taken that no effluvia from them pass into the frame. Some leaves were sent to us the other day that were thoroughly destroyed by rank steam from dung linings. We did not need to be told, that in giving air the sash had been slid down, and thus the steam rising had free access to the interior. If such sashes had been tilted up at the back, the steam from the front linings, however rank, might have risen, but it would not have passed into the frame. It is just such simple matters as these, when the roughest materials must be used without much preparation, that make all the difference

between success and failure. The sliding down a sash for air, and the tilting it up behind, may thus be attended with very different results. In all cases where particular care is required, tilting is the safest, not to speak of deleterious steams entering from the front; no fresh air can then reach the plants at the back without first passing through the warm, moist air issuing out.

Under such circumstances, even the covering-up at night is a matter of importance. One man will throw on a mat and tuck it in nicely back and front, so that not a bit of it shall extend beyond the glass sash. Another will throw it on and let it hang over back and front—a matter of little moment if there is no lining, or if that is perfectly sweet, but likely to cause very injurious consequences indeed if rank steams are rising from the lining, and these by means of the overhanging mat are encouraged to find their way into the atmosphere of the frame, through every chink, opening, and lap in the glass.

Our readers will excuse with their usual kindness this digression that has taken us so far from the second mode of keeping the rain falling on the glass from passing into the front of hotbeds, and thus soaking and cooling them, and that is the fastening a small spout in front for the purpose. Tin, zinc, or anything would do, the simplest of all, perhaps, being two slips of wood three-quarters of an inch thick, and 3 inches wide, bevelled and fastened together by the edges so as to resemble the letter V, and one side fastened in a sloping direction to the frame, some simple means being provided to take the water away from the lowest end. A little tar, or pitch, run along the angle of the V makes all water-tight. Such a simple plan saves the front of a hotbed from becoming cooled and drenched.

FRUIT GARDEN.

Strawberries.—These, if gathered in bright weather and before watering the pots, we always consider at this season to be preferable to those obtained out of doors. It always goes so far against the grain to gather Strawberries for table, and even more so to pack them for sending away, immediately after the plants have been watered. They travel worse, and the flavour is not so good. There is almost as much difference as between gathering a dish out of doors in bright sunny weather, and gathering a dish after several days' rain, and little or no sun. The end of May has always proved with us the most troublesome period as respects Strawberries, and chiefly because then we are generally obliged, much against our will, to give a portion of them a place to themselves, instead of continuing, as at other times, to make them merely a subsidiary crop. As yet in a lean-to Peach-house about 11 feet wide, with trees on a front trellis, and trees against the back wall, we have still four rows of Strawberries which receive justice—that is, a row suspended about a yard from the back wall, another row suspended about the middle of the house, a third ripening its fruit between the two—at the top of the trellis—and a fourth row near the front. These receive all justice from free exposure to every ray of sunlight; and as we can bring a circulation of air all over them and near the glass, we can set the fruit in this house at an angle of 45°, as we can do nowhere else with so little trouble. As soon as the Peach-house is started, we therefore set the fruit of Strawberries here, and take them into other places, warmer or cooler, according to circumstances, to swell and ripen. As the Peaches, however, are swelling to ripening, we must take all these pots gradually away, so that the fruit, and the wood, too, of the Peaches may have the advantage of the full sun unobstructed by these suspended shelves.—R. F.

COVENT GARDEN MARKET.—MAY 19

Among our imports this week we have received, in addition to those named in former reports, Apples and Strawberries, neither of which, however, came to hand in good condition. Cherries also have been very damp. Peaches and Netaines are improving. The supply and demand are about balanced, with the exception of Strawberries, which have maintained a high price during the week.

FRUIT.

TO CORRESPONDENTS.

INSECT ON VINE (T. Haeckel).—It is the Vine scale (*Coccus vitis*). You may destroy it by brushing it over with a creamy mixture of soft soap and flowers of sulphur in water.

MRS. FOLLOK GERANIUM BECOMING GREEN (Y. Y.).—All variegated Geraniums have a tendency to return to the green state. If the plant is kept in a shady place there is a greater tendency. It is just possible that there might be a mistake as to the plant in your case. The *Trifolium repens* is the hardy creeping white Clover found in meadows, not the brown Clover.

NEW HOE (J. Crick).—The hoe of which we gave a drawing on p. 829 is an American invention, and not patented in this country. It needs no trial, for any gardener can at once estimate its merit.

PLANTS FOR STANDING IN POTS IN WATER (J. C. B.).—If you wish for something with large foliage, then *Lichardia thopiica* and its variegated variety *L. albo-maculata* would do from May to October; and if for something very neat, then *Isoplepis gracilis* placed on inverted saucers so that the pots would be an inch or two in the water, and so close together that the leaves may meet. *Cyperus alternifolius* would look well. These would only do from May to October. If you wish for something permanent, then we would plant *Hydrocharis morsus-ranae*, *Utricularia vulgaris*, and *Hottonia palustris*, or any of the smaller-growing aquatics, planting in an inch of mud and the same depth of sand.

PLANTING TROPYOLIM CANADENSE AND LOPHOSPERMUM SCANDENS (A Subscriber).—Your plants, if well hardened off, may be planted out by the side of a house, but they will not do well on a north aspect.

RUST ON GLADIOLI (Tullyhallan). We know of no cure; but we find a top-dressing of rich compost, and plentiful supplies of water in dry weather, and syringing or sprinkling overhead in the evening of hot days with aired water, do much to lessen the evil. The soil has much to do with it. We think of soil partaking more or less of a peaty nature they are rarely attacked.

VERUSSEVIA (IRIS) PAVONINA AND CAMASSIA ESCULENTA (G. S.).—These bulbs are quite hardy, but grow indifferently in cold situations and in wet heavy soils. They require warm situations, and well-drained loam inclined to be sandy, and if those be secured to them they do well. Both are fine for pot culture; and if your situation is at all cold or exposed, you will succeed better by growing them as you did *Camassia esculenta*, in a cold house. They are very ornamental for the greenhouse and conservatory.

BOOKS (A Subscriber).—London's "Self Instruction for Young Gardeners," directs how to measure timber. We cannot give the details, for it is a common arithmetical proceeding. Stephens' "Book of the Farm" is one of the best books on agriculture. (T. D. R.).—London's "Self-Instruction for Young Gardeners," gives the information as to seed-drawing, which you require. It is published by Messrs. Longman & Co.

TWINGING TREES (Scott).—Some, as those of the *H. myrsinifolia* and *Black Bryony*, follow the apparent motion of the sun, twisting round their support from left to right. Others, as the *Great Bindweed (Calystegia sepium)*, twist the contrary way—namely, from right to left. They never change the direction of their twisting—that is, the *H. myrsinifolia* and others never twist from right to left, and the *Great Bindweed* never twists from left to right. If grown in the dark, twining plants lose the power of twining; but directly they are restored to the light, and renew a healthy growth, they resume their natural direction in twining.

PRICES IN HENRY VIII'S REYN (J. P. S.).—We cannot undertake to calculate whether other fruits and cuttles bore a price proportionate to the Lemon, which then cost "six silver pennies;" but we can add the prices paid for some articles for the King's use when residing at his Greenwich Palace in the October of 1518. 2 Doz. Fat Capons, 48s. Pigeons, 32 doz., 28s. Rabbits, "souters," 2 doz., 5s. 8d. Cornes, 3 doz., 6s. Cress, 5 dozen and 8, 23s. 8d. 4 Peacocks, 8s. 18 Peaches, 8s. Eggs, 250s. 3d. Apples, 1200, 6s. 8d. Onions, 15 bunches, 15d. Quinces, 220, 6s. 8d. Herbs, 4l.—(Letters and Papers Temp. Henry VIII, by J. Brewer. Published by Direction of the Master of the Rolls, ii. pt. 2, p. 1515.)

REBON-BORDER (M. H.).—All the three plans would do well, but there might be a difficulty as to height. Using your materials, we think the following would be an improvement, beginning at the back:—*Perilla*; *Calceolaria stravis* yellow, as *amplexicaulis* or *Aurantia multiflora*; *Geranium*, as *Stella* or *Boule de Fen*; Variegated Mint; Purple King *Verbena*; *Calceolaria*, dwarf yellow; scarlet *Verbena*; blue *Lobelia*; *Cerastium*.

INSECTS (A Subscriber).—Your insect is the common aquatic *Notonecta glauca*. (C. C. E.).—The red eggs are those of the Bark Mite. The caterpillars had escaped, the box having been crushed in the post.—W.

SEKLE PEAR (Jey. C. C. E.).—We have received the twig, but can see nothing peculiar about it, except that the post-office officials had squeezed and punched it quite flat.

VINE LEAVES DISFIGURED (*H. P.*).—The leaves were too withered to enable us to decide absolutely the cause of the disfigurement. There seemed to be a few marks, as if there were traces of mildew, but we could not be certain. However, the bulk of the spotting left no doubt on our mind that sewing with hot vapour was the chief cause, most likely produced by sewing air too late in the morning. We would advise discontinuing syringing at night, putting a little fire on in cold nights, and leaving a little air on all night at the highest point of the roof, giving more as the sun acquires power. This will prevent the accumulation of close heated vapour.

NAMES OF PLANTS (*M. J. S.*).—*Berberis Darwinii*. It is a native of the

coast of South Chili, where it was discovered by Mr. Darwin, but was first introduced to this country by Messrs. Veitch. (*A Subscriber*).—The flower is evidently a *Viola*, but was quite smashed when received. It may be valuable for spring bedding, but to determine that the plant must be seen. (*Prosperal*).—We are sorry again to say that it is impossible to name the scraps sent. (*B. H.*).—*Sedum carnosum variegatum*. (*J. G. Beaman*).—From the fronds sent we see no reason why it should not be *Lomaria gibba*. (*Messrs.*).—1, *Polystichum aculeatum* var.; 2, *Cyrtomium falcatum*; 3, *Scopolopodium vulgare*; 4, *Asplenium*, insufficient for determination; 7, *Oncidium japonicum*; 8, *Platyloma rotundifolia*. (*A Constant Reader*).—1, *Calathea zebrina*; 2, mislaid; 3, *Cytisus purpureus*; 4, *Cytisus biflorus*; 5, *Prunus padus*; 6, *Coronilla emerus*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 19th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PREVENTING FOWLS SCRATCHING.

We have received the following inquiry:—“Can you tell me of any plan to prevent Bantams scratching in flower-beds? I have tried sewing up their feet in canvas, but do not find it effectual.”

We think that the handwriting is that of a lady, and she adopts the motto, “Firm.” If she be “firm of purpose,” then she may carry out the suggestion offered in this letter from another correspondent, “W. Parker:”—

“I lately received a letter from a son of mine who is at Port Natal, in which he says—‘Up the country where I have been, they have the most clever way of preventing the fowls from scratching the ground that ever I heard of. They cut the fowls’ toes off when they are first hatched, and I can assure you that it is a perfect remedy, for it is impossible for them to scratch afterwards.’”

So we should have concluded without any such assurance! The frost often does in this country that which the natives do at Port Natal—it takes off the nails of the fowls, and in places where they have the run of the kitchen in cold weather, they get into the wood ashes and burn their nails off. This, we expect, is the African operation. The *nail* only is removed. This would matter little in a light soil, as the toes will turn over leaves, or loose earth; but if the *toes* were removed they would be poultry “Widdringtons,” and “hobble on their stumps,” even if they were not altogether incapable of locomotion.

To “Firm” we can state no plan for preventing Bantams scratching; but our plea for them is, they are searching for our garden enemies when they scratch. They are hunting for creatures that do far more mischief than they do. On their behalf we plead guilty to untidiness.

A gentleman was complaining to us once of the damage done by Pheasants to the farm crops. We had a hen Pheasant at hand, and opened the crop to examine its contents. It contained seventy-one grubs. These would have destroyed twice as much food as the Pheasant would have eaten, and would have given birth to other insects which would have multiplied geometrically.

CIRENCESTER POULTRY SHOW.

The schedule of this proposed Show is now in print, and for the amount of entry payment the prizes are very liberal. Spanish, Dorking, Cochins, two classes; Brahmas, dark and light, each a class; Game, two classes; Hamburgs pencilled, Hamburgs spangled, Bantams, two classes; Ducks, three classes; any other variety, first prize 30s., second 10s.; the any other variety Dorking, Buff Cochin, and Black-breasted and other Red Game have a third prize of 7s. 6d.; the selling class has also the same amount of prizes. The entry is the very

moderate amount of 3s., the Show a one-day show, and the occupants of the pens to be one male and one female.

Besides these there are sweepstakes for single cocks 5s. each; these are never very popular, but there is the extra inducement of a silver cup for the best bird in the eight classes, in addition to the winnings. There seems to be an omission as to the restricted price for the selling class. There also appears to be an omission of a Poland class; there is plenty of time to alter this, indeed it would be easy to add a slip to each schedule as sent out. For a first attempt, it is very good. Let the southrons show that they can fill the pens and support it.—Y. E. A. Z.

SHEFFIELD POULTRY SHOW.

This was opened on the 19th inst. and closes this day. Subjoined are the awards, but we must defer our remarks till next week.

SPANISH.—First, and ease of fifty-three pieces of cutlery, H. Beldon. Second, Messrs. Burch & Boulter. Third, W. Harvey. Highly Commended, J. Thresh; J. Ridpath. Commended, A. O. Worthington; J. Thresh.

DORINGS.—First, Mrs. F. S. Arkwright. Second, Sir St. G. Gore. Third, T. Burgess. Highly Commended, H. Saville; Sir St. G. Gore. W. Harvey; Admiral Hornby.

COCHIN-CHINA (Cinnamon and Buff).—First, C. W. Brierley. Second, T. Stretch. Third, J. Cattell. Highly Commended, R. W. Boyle; A. E. Watkin. Commended, J. Poole.

COCHIN-CHINA (Partridge and Grouse-feathered).—First, J. Stephens. Second, E. Tudman. Third, T. Stretch. Commended, T. Bott; E. Tudman.

IBRAHMA POOTRA.—First, J. H. Pickles. Second, R. W. Boyle. Third, F. Powell. Commended, R. W. Boyle; W. Harvey.

GAME (Black and Brown-breasted Red).—First and Third, Sir St. G. Gore. Second, Hon. H. W. Fitzwilliam. Highly Commended, C. Challoner; T. Burgess. Commended, S. Matthews; Hon. H. W. Fitzwilliam; G. Hellewell.

GAME (Any other colour).—First, G. Hellewell. Second, W. J. Cope. Third, C. Challoner. Commended, Sir St. G. Gore; F. Sales.

HAMBURGH (Golden-pencilled).—First, H. Beldon. Second, T. Wrigley, jun. Third, C. Tattersall. Commended, R. Burrow.

HAMBURGH (Silver-pencilled).—First, Sir St. G. Gore. Second, E. D. Yeardeley. Third, A. K. Wood.

HAMBURGH (Golden-spangled).—First, A. K. Wood. Second, H. Beldon. Third, J. Newton. Highly Commended, S. Mills, jun. Commended, J. Buckley; Sir St. G. Gore; J. Roe.

HAMBURGH (Silver-spangled).—First, and Liqueur Stand, J. Fielding. Second, A. K. Wood. Third, Sir St. G. Gore. Highly Commended, Sir St. G. Gore; H. Beldon; A. K. Wood.

POLISH (Black with Crests).—First, S. Farrington. Second, E. J. Proctor.

POLISH (Any other colour).—First, Second, and Egg-stand and Spouts, H. Beldon (Golden). Highly Commended, Sir St. G. Gore. Commended, E. Smith (Silver-spangled); W. Silvester (Golden).

BANTAMS (Game).—First, Sir St. G. Gore. Second, E. Foder (Black-breasted Red). Third, H. Shumach.

BANTAMS (Black or White, Clean-legged).—First, J. W. Morris (Black). Second, Sir St. G. Gore. Highly Commended, Sir St. G. Gore. Commended, E. Cambridge (White).

BANTAMS (Any other colour).—First, Messrs. S. & R. Ashton (Silver-laced). Second, H. Beldon (Japanese Bantams).

ANY OTHER DISTINCT BREED.—First, Hon. H. W. Fitzwilliam (Crève Coqns). Second, F. W. Zuerhorst (La Fleuche). Third, J. O’Leary (Minorca). Highly Commended, Rev. G. Hustler (Holland); E. W. Zuerhorst (Sultan); H. Beldon (Black Hamburg); R. Loft (Sultan). Commended, W. Dawson (White Cochin).

SINGLE COCKS.

SPANISH.—First, H. Beldon. Second, T. B. Hartley. Commended, J. Thresh.

DORKINGS.—First, Sir St. G. Gore. Second, Rev. T. O'Grady. Commended, W. Harvey.

COCHIN-CHINA.—First, W. Harvey. Second, J. Bradock. Highly Commended, B. W. Boyle.

GAME.—First and Second, C. W. Brierley. Third, Sir St. G. Gore. Highly Commended, H. Crossley; Sir St. G. Gore. Commended, A. B. Dyas.

HAMBURG (Pencilled).—First, H. Beldon. Second, Sir St. G. Gore. **HAMBURG (Spanish).**—First, Sir St. G. Gore. Second, J. Fielding. Highly Commended, J. H. Turner.

BANTAM (Game).—First, Sir St. G. Gore. Second, J. Crossland, jun. Third, J. A. Collinson. Highly Commended, Hon. H. W. Fitzwilliam. Commended, R. Tate; J. W. Morris; H. Buckley; J. Fryer.

GAME HENS.—First, Sir St. G. Gore. Second, C. Colloper. Highly Commended, J. G. Pearson; W. Bradley. Commended, W. Hargreave; C. Challoner.

PAIR OF HENS (Any variety).—First, Messrs. Burch & Boulter (Spanish). Second, Hon. H. W. Fitzwilliam (Dorking). Highly Commended, W. Roberts (Dorking Game); Sir St. G. Gore, Bart. (Belands); G. H. Roberts (Prahma Pouter); R. E. Goodall (Pencil Hamburg); W. Silvester (Golden Polish). Commended, J. G. Pearson. C. J. Dourndorings.

DUCKS (White Aylesbury).—First and Second, J. K. Fowler. **DUCKS (Roman).**—First, Sir St. G. Gore, Bart. Second, G. Westenhelm.

DUCKS (Any other variety).—First, T. C. Harrison (Maudslayi). Second, J. E. Jessop (Carolina Ducks). Highly Commended, Sir St. G. Gore, Bart. (Grey Gulls).

SELLING CLASS.—First, H. Saille (Sebaston Goose and Gander). Second, G. H. Roberts (Prahma Pouter). Third, Messrs. Hinde and Farniss (Silver-pencil Hamburg). Highly Commended, Rev. P. W. Story (White Feather-legged Bantam); J. Stephens (Laced Bantam); J. Booth (Silver-spangled Hamburg). Commended, H. Beldon; F. Powell; T. Dyson (Silver-pencil Hamburg); E. Loft (Sultan); J. Marchant (Spanish).

PIGEONS.

CARRIERS.—*Cock.*—First, Miss E. Brown. Second, J. Smith. Third, R. Fulton. Commended, F. Power. *Hen.*—First, R. Fulton. Second, G. F. Statter. Third, — Furth, jun.

POWTERS.—*Cock.*—First, W. Harvey. Second, R. Fulton. Third, G. Westenhelm. Commended, Miss E. Brown; G. Crookes; H. Brown. *Hen.*—First, F. Key. Second, W. Harvey. Third, R. Fulton. Highly Commended, W. Harvey.

TRUMPETERS (Almond).—First, R. Fulton. Second, F. Key. Third, E. D. Yardley. Commended, F. C. Bradley; Miss E. Brown.

TRUMPETERS (Any other variety).—First, R. Fulton (Short-faced). Second, H. Yardley. Third, G. Westenhelm (Mottled). Highly Commended, F. C. Bradley (Black Kite); H. Yardley.

OWLS.—First, J. Fielding, jun. (Blue Owls). Second, H. Yardley. Third, W. Pepper.

TURBETS.—First, W. T. Wilkinson, jun. Second, Miss E. Brown. Third, H. Yardley.

FANTAILS.—First and Third, H. Yardley. Second, W. Pepper.

JACOBIENS.—First, Miss E. Brown. Second, Messrs. C. & E. Roys. Third, H. Yardley.

BARDS.—First, H. Beldon. Second and Third, H. Yardley. Highly Commended, G. H. Roberts.

DRAGONS.—First and Third, H. Yardley. Second, W. Harvey.

ANY OTHER DISTINCT BREED.—First and Third, H. Yardley. Second, W. Harvey (Yellow Swallows). Highly Commended, H. Beldon. Commended Miss E. Brown (Swiss); H. Yardley.

SELLING CLASS.—First, Messrs. C. & E. Roys (Swiss). Second, J. J. Wilson (Mottled Trumpeters). Third, H. Beldon (Yellow Turbits).

The Judges were Richard Teohay, Esq., of Fulwood, near Preston, and Edward Hewitt, Esq., of Sparkbrook, near Birmingham.

LIGURIAN BEES.

In your impression of the 18th of July last you were kind enough to insert some rather crude notes from my journal in reference to a stock of Ligurian bees from Mr. Woodbury's apiary. Since that time I have been entirely successful in raising four queens artificially by following Mr. Woodbury's directions in your Journal, and it is only fair to add that I have found every direction coming from that gentleman quite to the point, and very practical.

I am sorry to have to say that in consequence of a little delay in early spring feeding I lost one of my young queens with her subjects, to the number of three thousand. Notwithstanding considerable care, a second hive was blown over during winter, and to prevent a chill I never ventured to lift off the top and inspect them until sunny weather came. On lifting the cover I found the combs and frames in a state of confusion, which I could not have believed possible from a tumble. However, thanks to the form of hive, I succeeded in putting in fresh comb and making matters more comfortable. The hive is now all right, only a little weak. Of my four queens then, I have three left. Of these three I am sorry to say that two, at any rate, are hybrids; but I am not sure about the third, as many of the bees are very yellow.

But now let me say a word about my pure Italian queen. For some time I watched the conduct of the bees in her hive, and was by no means pleased at their want of activity and the absence of bees carrying pollen. After two inspections my worst fears were realised. I found neither brood nor eggs.

Alas! she is dead, and with her my sanguine hopes of several pure Italian queens this season. Will Mr. Woodbury kindly tell me how to proceed, since I cannot feel myself a successful apianian, if I find it needful to obtain a fresh stock of Italians each spring? I fear such a plan would add largely to the debit side of the bee account. I see no plan, however, but procuring another queen, and in this matter I should like advice. I may just add, that when I found the queen missing I added a brood comb, and have to-day had the pleasure of seeing a sealed queen cell.—E. B. CLIMES, *Chamberland.*

I much regret the misfortune of my clerical friend, for which, however, he has suggested the best remedy—viz., the obtaining another queen. I hope ere long to have the pleasure of forwarding to him a pure queen at the head of a small swarm, which he will introduce into the well furnished hive of a stock of common bees (the rightful inhabitants having been previously expelled by driving), and thus form a good stock without the risk of uniting.—A DEVONSHIRE BEE-KEEPER.]

TOMTITS EATERS OF BEES.

NEGATIVE evidence must always give way to positive testimony, and I am glad to find from the reply of Mr. Goodsall, that he has been an eyewitness of the ravages committed by the tomtit. The species to which I alluded as innocuous corresponds to the description given by Maunder of the "Cole Titmouse" (*Parus ater*). If the same, it is very common in the south of Scotland, and the only species that frequents the district in which I reside. I paid particular attention to its habits in the apiary during last winter, and I am bound to say that it seldom visited my hives, except when snow was on the ground, or the day so chilly as to benumb such bees as lingered a short time while out of doors. When suffered to approach the hives and act as instinct dictated, I failed on every occasion to detect it seize either emerging or returning bees. The inactive alone fell a prey.

Being curious to know what the stomachs of tomtits contained, I had two of them shot and dissected. The contents showed a small portion of the bee mixed with a large amount of other insects. I will not affirm that this species to which I refer never destroys bees in an active state, but certainly it is a foe as little to be dreaded in the apiary as either the hedge sparrow or the chaffinch, and should excite no uneasiness in the mind of a bee-master.—R. S.

EARLY LIGURIAN SWARM.—The first swarm that I have heard of in this county issued from a hive of Italians in my own immediate neighbourhood during the forenoon of Sunday last, the 13th inst. The parent stock left my apiary last year, and has thriven remarkably well in its present locality.—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

DORRING CHICKENS DYING. (J. G. C.)—Seven found dead one morning in the coop, together with one Sparrow; four more dying during the day and another Sparrow, are strong circumstances—evidence that poison was mixed with the food. This could not be determined without having it analysed, for there is no inflammation of the crops indicating acid poison, and the grains of wheat in the crops of all are ungested.

FOWLS LOSING THEIR FEATHERS. (M. Brighton.)—You do not mention the breed of your fowls, but from experience we believe they are Spanish. We had a yard of that breed last year, and many were almost naked, having little more than the tail and wing feathers. They began to lose their feathers at this time. They never suffered in health. The only treatment we adopted was to remove any of the hens that had an inclination for picking their companions' feathers, to avoid all stimulating food, and to give them a large grass run. We then tried a good supply of lettuce, which seemed very effectual in staying the plague. It did not restore the plumage, but it prevented further inroads on it.

SWOLLEN CROPS.—**BANTAMS EATING BACKWARDS.** (*Inquirer*).—It is not wind in the Dorking hen's crop; it is water. You must take her by the legs, and hold her head downwards till the crop is empty; then confine her in some place where she can have only such food as is given to her. Let her have water four times a day, a small quantity each time, and let the water-vessel be taken from her as soon as she has drunk. By adopting this plan the crop will contract. Food should be given very sparingly. The Bantam hen has what old women call the "gids," and you may kill her. The place you mention is quite large enough for the hens to sit, but the space is not enough for them to come off. We should consider it detrimental to health, and it might cause the attack you mention.

PIGEONS.—CHICKENS. (*A New Subscriber*).—If you send twenty postage stamps with your direction, and order "The Pigeon Book," you will have it sent from our office free by post. Let the coop be in the open air during fine days, and in the greenhouse at night and during wet weather. Let it stand on the gravel walk close to the grass.

WEEKLY CALENDAR.

Day of Month	Day of Week.	MAY 29—JUNE 4, 1866.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.		Moon Sets.		Moon's Age.	Clock after Sun.	Day of Year.
			Day.	Night.	Mean.				m.	h.	m.	h.			
29	Tu	Jacksonia grandiflora.	66.9	44.3	55.6	13	58 af 3	1 af 8	49 af 7	11 af 3	O	2	55	149

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 68.97; and its night temperature 44.5. The greatest heat was 85, on the 3rd, 1816; and the lowest cold 25, on the 23th, 1834. The greatest fall of rain was 0.97 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

SILVERY EDGING PLANTS.

N compliance with various applications I will enumerate as many as I remember of silvery or greyish-looking edging plants, and add a few notes on their culture.

1. *ACHILLEA CLAVENNE*.—This is a neat finely-cut-leaved plant, growing to the height of 6 inches, yielding white flowers; but if these are pinched off the plants make a dense silvery edging. The plant is easily propagated by cuttings and divisions of the root, and is quite hardy, except in wet places and very stiff soil. It likes sandy loam best, and is there quite at home.

2. *ANTENNARIA MARGARITACEA*.—The flower-stems and flowers, which are white Everlastings, grow about 18 inches in height, but when these are nipped off a dense white greyish carpet is produced by the hoary shoots. The plant is quite hardy, and is easily propagated by cuttings and divisions. It does best in a dryish soil, and the finest edgings are made when the plant is fresh planted every year early in the spring.

3. *ANTENNARIA TOMENTOSA*.—A still lower-growing smaller-leaved plant, producing beautiful yellow everlasting flowers, which are sold dyed of many colours in Covent Garden. When the flowers are removed, or not allowed to grow, the plant makes a neat greyish edging. Propagated as above, but the plant delights in a dry sandy loam.

4. *ARCTOTIS REPTANS*, a creeping plant with whitish leaves, does better for carpeting than for edgings, and does also well for suspended baskets. Propagated by cuttings, and requires to be kept dryish and secure from frost in a cool greenhouse in winter. As it carpets the ground it grows about 6 inches in height.

5. *ARCTOTIS ARGENTEA*.—This also has silvery leaves, but it is stronger and more upright in growth.

6. *ARTEMISIA ARGENTEA*, an elegant plant with silvery grey tripinnate leaves that grows rather strong, but by cutting once or twice will form an elegant edging of from 7 to 12 inches in height. Propagated by cuttings and divisions. I believe it is pretty hardy in some places, but in general it requires protection in winter.

7. *CENTAUREA GYMNOCARPA*, *CANDIDISSIMA*, AND *RAGUSINA COMPACTA* are all very beautiful, and produce fine white foliage in dryish ground and when fully exposed to the sun. Last season I might say I had hundreds if not thousands of them, and this season I have not so many scores, and it is entirely my own fault in not liking to disturb the beds and lines to take cuttings in time. If plants are taken up, and divided in July and August, or even cuttings are taken off at that time, every bit will strike, if ordinary care be taken to prevent damping, and one of these little

bits struck will have a better chance to pass through the winter than old plants taken out of the ground, however carefully managed. Small bits will also strike freely in spring in a little dryish heat. It is a good plan where there are some old plants to top them in February, and then in March they will throw out a lot of shoots 2 or 3 inches long, which strike freely round the sides of a pot. My past success, however, leads me to place the most dependance on July and August cuttings, and to keep the plants in but little room as to pots and soil, and rather dryish all the winter, and so that the frost cannot reach them. I went on from day to day last autumn, something or other keeping me from putting the cuttings in, and then I thought I could not be much amiss with so many old plants in the ground; but I was so late in taking them up that I did little good with them. The great secret of success is to divide or strike early, so as to have the plants well rooted and established before winter. Young plants do best for edgings. If kept dryish they will stand plenty of air and cold in winter, if frost be excluded.

8. *CERASTIUM TOMENTOSUM*.—This is the best dwarf, grey, silvery-edging plant we have, and, except in damp places, is perfectly hardy. I have frequently cut-in and dressed for the present year the edging that was formed last year, and chiefly to save time; but in general, and in lightish soil in particular, the best effects are produced by planting the edgings afresh every year. This may be done by dibbling in thickly the little bits of uniform size without roots; better still by dividing the plant and planting with a bit of root; and, perhaps, best of all by selecting an out-of-the-way border in autumn or winter, forking it over, heating it level, and dibbling little bits in rather closely together. These by April and May will be nice compact-rooted plants, and if planted regularly, and once watered will require little more trouble during the season, except cutting off the beautiful white flowers, and trimming the plants to keep them in shape.

9. *CERASTIUM BIEBERSTEINI*.—This is a stronger-growing plant, and the little shoots are stronger, and not quite so upright and pearly as *tomentosum*, but it is a very desirable edging plant. In dull damp weather on strong land it is not quite so pearly as *Cerastium tomentosum*; it may be managed in the same way, but it is even less tolerant of damp in winter. In damp places I find it has gone during the last winter, whilst in drier places it shows how soon it would carpet the whole ground.

10. *CISERARIA MARITIMA*.—This, on account of its beautiful, cut, hoary, and, in fine seasons, frosted silver foliage, I like as well as the *Centaurea*, and it is much hardier, standing in dryish positions through our common winters. Such plants if let alone will grow from 2 to 3 feet in height, and produce their coarsish yellow composite flowers, and yield abundance of seeds; and from these, if sown in a hot-bed in March, seedlings in plenty may be obtained for planting-out in May. It is rare, however, that these seedlings give in the first year the bright silvery foliage of older plants, or those raised from cuttings taken from older plants. When old plants left in the ground are to be retained as edgings, they should be cut down almost close to

the ground in April, or the beginning of May. Cuttings may be taken off and struck at any time, but they strike the most readily when from such cuttings as plants the young shoots or suckers are selected when firm at the base, and about 3 inches in length. They will strike quickly without any danger of damping if placed in a little hot bed. It is not desirable to wait for the cuttings from plant out of doors, some rather large established plants may be kept in pots, and cut down and placed in a hot bed in spring, when they will soon yield a lot of young shoots for cuttings. These spring-struck plants are the best of all for edgings, as they remain compact, and seldom throw up any flower-stalks during the first summer.

11. *DIORIS MYRTIFOLIA*.—A stiff shrub with silvery leaves covered with greyish down, which when pegged down is said to make a fine edging; but I have not seen it so used. I presume that it is equally hardy with others of the family, and, with the exception of the cutting and the pegging, requires only the commonest treatment.

12. *CERASTIUM LANCEOLATUM*.—A very useful edging plant with hoary leaves, capable of being managed so as to be 6 or 18 inches in height, in the latter case producing its bunches of bluish sweet everlasting flowers. It should be propagated by cuttings in August, and be rather dry in winter in any airy place, where frost will not reach it. The last frost destroys it when damp. We have some times allowed it to run wild round a bed, and to interlace itself among the plants behind, when it looked very graceful. By pegging and cutting it may be kept compact, and to any desirable height. The more sun it has the whiter it will be.

13. *SALICARIA ALBA*.—This, though Lady, does better for a bed or border than for edging, as it is generally from 2 to 3 feet in height, and looks best when growing upright instead of under edging treatment.

14. *SPARGANIUM LANCEOLATUM*.—A very hardy Siberian Hedge Nettle plant, with large, woolly, thick leaves, which in any case, and especially if the flower-stems are removed, makes a dense carpet on the ground. For this carpeting and for broad margins it is more suitable than the narrow edgings; but it is useful for many places, and has the recommendation of looking after itself pretty well wherever it has standing room. It makes roots so freely, that every little bit will grow. It looks whitest and most sparkling where it receives the most sun.

Of these plants specified, I prefer *Cerastium* for low edgings, and *Centaurea* and *Cineraria* when the edgings are to range from 6 to 12 or more inches in height.—R. Fish.

THE INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS.

"They manage these things better in France." How often that has been dimmed into our ears by writers of all kinds in gardening papers. Ladies, who are supposed to be the best arbiters in taste; dilettanti horticulturists, who know nothing of the practical working out of this fascinating pursuit; learned doctors, who out of their own consciences in their study evolve what might, ought, should, or could be done; travelled gentlemen, who have escorted some fair dame through the beauties of a foreign show;—have all told us that we do not know anything about flower shows—that our stiff and formal training, our huge pyramids of bloom, our boxes of cut blooms, are abominations; and that we had better either abandon them altogether, or else take a leaf out of the books of our continental friends. It was vain to assure them that all this was a mistake, that the shows abroad were got up as special things, that they bore no analogy whatever to our six or eight exhibitions held every season, for that they only took place every three or four years; that if the occasion came we could far outstrip them; and that in point of cultivation there was no comparison between the productions of our English gardeners and those of the best continental ones. And yet all has been most fully confirmed by the marvellous success of the great International Exhibition which has just taken place; and, yet, must all bear in mind that this is exceptional—it is no more to be expected every year than the Great Exhibition, on this site of which it was erected, is to be annual. In the opinion of all who know anything of flower shows, and in the judgment of our foreign visitors, never before has such an exhibition been held; and we hope that it may inaugurate as great an improvement in all branches of horticulture as did the Exhibition of 1851 in manufactures. There is this to cheer us, we think, in our horticultural shows—that whereas we, in 1851, had to learn

how far behind foreigners we were in our ideas of taste and elegance, we may perhaps reverse it now by saying that the foreigners will ascertain from us that in perfecting the productions of nature they have from us many lessons to learn.

And now what shall we say, or how attempt to describe, this marvellous display? There are thousands of the readers of *The Journal of Horticulture* who will not have been able to see it, and who would gladly know what it was like. One would want an essence made of all the Rose leaves in the Exhibition to dip one's pen in to give that recite hue to one's description that it ought to have. Of what use is it to tell them that there were three acres and a half covered with canvas, making a tent 563 feet long by 293 broad—that the skill of one of the ablest landscape gardeners we have, Mr. Gibson, of Battersea Park, and his accomplished son, had been called into requisition to lay it out—that not only the most celebrated growers of our own land, both amateur and professional, had made the most wonderful efforts to outrival one another, but that the celebrated names of Linden, Verschaffelt, Tinbaut and Ketcher, and other foreigners were to be found amongst the exhibitors—that Madame Legrelle d'Annis sent some of her productions—that the Director of the Royal Gardens at Kew forwarded some magnificent specimens—and that the Crystal Palace Company were also competitors with some of their noble tree Ferns? All this to those who were there will afford some notion of what it was; but we fear that to make it at all intelligible to those who have not seen it is a difficult task indeed. If any of them have ever seen the Botanic Society's shows, then we may say, Multiply that twentyfold, and you may form some notion of what this great tent was. On entering you were at once met very wisely, not by a grand outburst of colour and beauty, but by a screen of Pines, Yews, pyramidal Box, &c.; and on going round this, on either side, itself being a good deal raised, you then obtained a view of the magnificent display. Everything had been done to give effect to the *tout ensemble*. Backwork had been raised, over which water trickled, and ought to have had an outlet to keep it clear, while on the rockwork were placed some of those fine specimens of British Ferns which Mr. Ivory knows so well how to produce; then there were little valleys of Rhododendrons, which were planted in the soil; while all around, on grass mounds and terraces, were placed such gorgeous masses of bloom in Azaleas, Geraniums, and Roses; such wonderful variety of form and colour in the different classes; that it was impossible to take in all at once, or in lead at all. You were continually stumbling upon something you had overlooked, or been drawn off from by some "maniae" to admire a special hobby of his own. And then when one passed from this great central tent into the Orchid tent, where were placed not only these valued and valuable flowers, but all the new introductions of Linden and Verschaffelt, of Veitch, and Bull, and Williams, how difficult not to feel that satiety which comes after such a visual feast as this, as does the same sense to the aldermen of St. Thomas Backchurch after my Lord Mayor's feast, when callipah and callipee, and salmon, and venison, fat capons, &c., have been laid under contribution! And then what a delightful *reunion* it was to meet men from all parts; some who had known a smooth-faced boy, and could hardly believe he was "grandpapa;" others whose hospitality he had shared abroad, and with whom he had had many a pleasant chat in their homes—Linden, and Verdier, and Verschaffelt, &c.; to be seized by one friend, who would say, "I must let you and—know one another;" to be accosted by lovers of flowers that we had never seen, but who knew us; to meet those with whom one had fired a long range shot, and to find that a hearty shake of the hand dispelled all the fogs and mists that too often arise about one's writing, because we will attach meanings to one another's words they were never intended to bear. There are some days which we mark as "special," for one reason or another. We think few lovers of flowers but will say that the 22nd of May, 1866, is one to be marked with the very whitest of white chalk.

And we hope no general plant-lover, who wonders at the benighted ignorance of our florists, will say, "It's like their impudence," when we assert that to them the main beauty of the Exhibition was to be attributed. We do not by this mean for a moment to detract from the merits, the great merits of Mr. Gibson, to whom, above all others, we believe the main success of the Exhibition, as such, is due; but what would Mr. Gibson have done without the "Florists?" Would he not in despair have looked on the task before him, if he were told no Azaleas, Geraniums, or pot Roses were to be

admitted? Not all the curious forms and fantastic leaf-colouring, not all the beautiful greenhouse plants, or waving Ferns, would have redeemed the Exhibition from the lack of colour, which even with them some maintained to exist. And let us add, that these three classes were those which most especially struck our foreign friends. We asked several of the most distinguished amongst them what was the feature in the Exhibition that most struck them, and the general reply was the Roses, Pelargoniums, and Azaleas. We expected that the formal training of the latter would have been offensive to their ideas and taste; but they said, No; the style was different, it was true, to theirs, but it was much more difficult. We may demur to this, for, we confess, a less formal style, as we have often said, would please us better; but it is hopeless to do this until some exhibitor has the "pluck" to do what was once done in Fuchsias—go out of the beaten track and exhibit a set naturally grown; and if the Judges would then award it, if *cateris paribus* it were worthy of it—the first prize, harlequin's wand would not more quickly effect a transformation than it would, and we believe all persons of taste would hail the change with pleasure.

Now as to Roses. The class for ten Roses in pots, not more than 13 inches across, was most warmly contested. We candidly say we did not envy the Judges their task here, so evenly balanced were the two collections of Mr. Turner and Mr. W. Paul; but we believe the greater evenness and freshness of those of the former grower carried the day. They consisted of Victor Verdier (H.P.), Souvenir d'un Ami (Tea), Vicomte Vigier (H.P.), Général Jacqueminot (H.P.), Madame Damaizin (Tea), Souvenir de la Malmaison (E), Baronne Prevost (H.P.), Charles Lawson (H.C.), a magnificent plant, and Madame Bill (H.P.). Mr. Wm. Paul's collection contained Madame de St. Joseph (Tea), Général Jacqueminot (H.P.), Souvenir d'un Ami (Tea), Caroline de Sansal (H.P.), Paul Perras (H.C.), Juna (H.C.), Louise Odier, Madame Villermoz (Tea), Comtesse de Chabrilant (H.P.), and Baronne Prevost. The third prize was gained by Messrs. Paul & Son with good plants of Madame de St. Joseph, Céline Forestier, John Hopper, Souvenir d'un Ami, Niphotos, Paul Ricaut, Madame Julie Duran, and Charles Lawson. These last three were beautiful plants. One wondered why Messrs. Lane's collection was not *decoré*, for it contained some beautiful plants, his Charles Lefebvre was a picture. Was it that he had but one Tea Rose? if so, we think this would be a point in his favour. They are the most easy to grow as pot plants, and, with rare exceptions, so hang down their heads as to require twice the number of props that those in the other classes take. Mr. Francis had also some nice plants, of which his Chénéoléf and Paul Perras were the best.

In the Class for Six New Roses (Class 112), not sent out previous to 1863-64, Mr. Wm. Paul was first with nice plants of Madame Victor Verdier, Alpaide de Rotadier, Elizabeth Vigneron, Pierre Notting (very fine), Madame de Stella, and Kate Hausberg. Messrs. Paul & Son were second with Paul de la Meilleray, Lord Clyde, Princess Mary of Cambridge (in spite of some adverse criticism, this is a fine Rose), Achille Gonod, Madame de Stella, and Alpaide de Rotadier.

For a single Rose in flower (Class 113), Mr. Charles Turner was first with a beautiful plant of Comtesse Cecile de Chabrilant, and Mr. Wm. Paul second with President (Tea).

Perhaps, however, the most interesting class in Roses was that for twenty in pots not more than 8 inches across (Class 114); for, after all, we believe this is the most attractive size, and is a class that ought to be much more encouraged than it is; they are so much more natural, and the larger number gives greater variety. Mr. Charles Turner was again first here with Souvenir d'un Ami, John Hopper, Charles Lefebvre, Vicomte Vigier, Alba Rosea, Charles Lawson, Prince Camille de Rohan, Vicomtesse de Cazes, Victor Verdier, C. line Forestier, Professor Koch, President, Anguste Mié, Général Jacqueminot, Madame Caillat, Madame Faleot, Alphonse Belin, Paul de la Meilleray, and Madame Damaizin. Mr. Wm. Paul was second with a nearly equal collection, comprising Bernard Palissy, Caroline de Sansal, Pierre Notting, Madame Alfred de Rougemont, Elizabeth Vigneron, Beauty of Waltham, Alba Rosea, President, Madame Clemence Joigneaux, John Hopper, Madame C. Wood, Comtesse de Brossard (Tea), Le Rhone, Victor Verdier, Madame Victor Verdier, Souvenir d'un Ami, and Rev. H. Dombardin. Messrs. Paul & Son were third with good plants of Charles Lawson, Catherine Guillot, Princess Mary of Cambridge, Alfred de Rougemont, Olivier Delhomme, Ladia, Madame Villermoz, Beauty of Waltham, Victor Verdier, Xavier Olibo (fine dark flower), Amiral Gravina, Alba Rosea, Belle Normande (pretty),

Adolphe de Rothschild, John Hopper, Madame Bonnet, Lord Clyde, Duchesse de Caylus, President, and Anna Alexief.

In the class of six standard Roses in pots (Class 115), Mr. W. Paul carried off the first prize with excellent examples of Vicomte Vigier, Paul Perras, Charles Lawson, Juna, Narcisse, and Elizabeth Vigneron. Mr. Charles Turner was second with François Lacharme, Vicomtesse de Cazes, Olivier Delhomme, Madame Bravy, Senateur Vaisse, and Victor Verdier. Messrs. Paul & Son were third with Devonensis, Madame Derrenx Douville, Souvenir d'Elise Varion, Alba Rosea, Adolphe de Rothschild, and King's Acre.

In boxes of cut blooms, twenty-five in three trusses of each, Mr. Mitchell, of Pittdown Nurseries, Mr. Wm. Paul, of Waltham Cross, and Messrs. Paul & Son, of Cheshunt, were exhibitors. Most notable amongst Mr. Mitchell's were some glorious blooms of Maréchal Niel, quite enough to bear out its character as the very finest yellow Rose in growth, not even excepting that coy maiden Chromatella (or Cloth of Gold); it did not, however, carry sufficient weight to bring its exhibitor the first prize, which was rightly given to Messrs. Paul and Son, the second to Mr. Wm. Paul, and the third to Mr. Mitchell.

The amateurs made a very creditable display, and showed that they have largely profited by the fine examples of Rose culture that the growers for sale have submitted to them of late years. Mr. Terry, Youngsbury House, Ware, took first prize in Class 111 with Madame Villermoz, Vicomtesse de Cazes (very fine plant), Paul Perras, Chénéoléf, Charles Lawson, and Comte de Paris, but it will be seen not one Hybrid Perpetual is shown here. Mr. Coleman, of Stoke Park, Slough, was second with Gloire de Saintenay, Charles Lawson, La Reine, Paul Perras, François Lacharme, Madame de Cambacères; while in cut blooms Mr. Coleman was first, and Mr. Hollingworth, of Maidstone, second.

The show of Pelargoniums was indeed magnificent, the most celebrated amateurs and professional growers having evidently done their very best, and sent in plants which were the astonishment of the foreign visitors especially. They were beautifully arranged in the centre circle, placed on the green bank, which threw up their flowers to the best advantage.

In Class 131, twelve show Pelargoniums in pots, not larger than 8 inches across, Mr. Charles Turner was first with Royal Albert, Lilacium, Fairest of the Fair, Beacon, very bright; Celeste, Lady Canning, a splendid plant; Pericles; Rosa Bonheur, a lovely bright flower with white throat; Desdemona, Puck, Mademoiselle Patti (beautiful), and Fair Rosamond. Mr. Fraser was second with Rose Celestial, Sir Colin Campbell, Empress Eugénie, Desdemona, Leander, Lilacium, Candidate, Peacock, Pericles, Norma (very fine), Ariel, and Pizarro.

In the Class for Fancies the order was reversed, Mr. Fraser being first and Mr. Turner second. Mr. Fraser's flowers were Lady Craven, Delicatium, Celestial, Cloth of Silver, Roi des Fantaisies, and Clara Novello. Mr. Turner's were Evening Star, Ellen Beck, Clemanté, Lady Craven, Delicatium, and Roi des Fantaisies. Mr. Turner also exhibited some plants of new varieties, among which were Mrs. Workman, Mary Hoyle (lovely), John Hoyle, Sunny Memories, Nabob, Exhibitor, Conqueror, British Sailor, and Charles Turner, a splendid scarlet flower; but perhaps the finest plants were those of Mr. Bailey's in Class 133, six plants, for amateurs. They were—The Belle, Mulberry, Ariel, Spotted Gem, Desdemona, Lady Canning, Etna, Sanspareil, Sir Colin Campbell, and Pericles. For six plants of show Pelargoniums (Class 133), the first prize was awarded to Mr. Donald, gardener to F. G. Wilkins, Esq., Leyton, for Osiris, Viola, Fairest of the Fair, Etna, Fair Rosamond, and Peacock; and the second to Mr. James Weir, gardener to Mrs. Hodgson, The Elms, Hampstead.

In Class 135, for six Fancies, the first prize was awarded to Mr. Bailey for magnificent plants of Godfrey Turner, Evening Star, Ellen Beck, Delicatium, Lady Craven, and Lucy; the second to Mrs. Hodgson. For one Pelargonium the first prize was awarded to Mr. Bailey for a magnificent plant of Rose Celestial; the second to Mr. Turner for Desdemona; and the third to Mr. Fraser for Sylph. Mr. Turner exhibited, as usual, some fine seedlings of Mr. Hoyle's, amongst which were Alfred, a beautiful dark flower; Lord Lyon, a splendid rich rose-coloured flower with white throat; and Favourite, dark. Alfred and Favourite received first-class certificates, why Lord Lyon did not we do not know. Mr. Hoyle exhibited a box of blooms of some of his best seedlings, and also some dried petals of Pelargoniums of sixty years ago, showing what progress had been made. This was very interesting.

STOVE AND GREENHOUSE PLANTS constituted a very important part of the display, and, from being in most cases placed in juxtaposition with masses of foliage, the effect was greatly enhanced. A collection of sixteen shown by Mr. F. Baimes, gardener to H. Micholls, Esq., Bowden, was a remarkably true example of successful cultivation. It consisted of two *IXORA*s—viz., *coccinea* and *aurantiaca*, the former with unusually large heads of bloom; *BORONIA pinnata*, flowering profusely; *ACROPHYLLUM venosum*, very fine; *Dipladenia cerasinoda*, *Genethyllis indipifera*, the flowers very large, as well as numerous; *Erica ventricosa coccinea* minor, fine; *E. Cavendishii*, a good specimen, but the flowers rather small; *E. tricolor*; *Eppisii*; *Azaleas* *Criterion*, *Extranei*, and *Icyrcana*; *Franciscana confertifolia*, *Aphelaxis macrantha purpurea*, *Epaeris-Echipse*, and *Eriostemon boxifolium*. In the same class Mr. Peed also contributed a fine collection, consisting of *Allamanda grandiflora*, the large yellow flowers of which were very effective; *IXORA alba*, fine; *Pimelea Hendersoni*, *Eriostemons*, a fine specimen of *Erica Cavendishii*, a large *Epaeris*, *Azaleas*, the pretty *Tetralochea ericaefolia*, good specimens of *Dracophyllum gracile*, and *Acrophyllum venosum*, the latter, however, not so large as Mr. Baimes's; *Genethyllis Hookeriana*, *Chorozeema cordatum splendens*, *Aphelaxis*, &c.

In other collections in the same class, besides plants already named, we noticed good examples of *Rhynchospermum jasmuoides*, the showy scarlet *Erica westphalanga*, *Boronia tetrandra*, *Pimelea spectabilis*, the deep blue *Leschenaultia biloba major*, *Clerodendron Thomsonae*, and *Coleonema rubra*.

Awards—First, Mr. Baimes, gardener to H. Micholls, Esq., Summerfield, Bowden; second, Mr. B. Peed, gardener to Mrs. Tredwell, Lower Norwood; third, Mr. J. Wheeler, gardener to J. Philpott, Esq., Stamford Hill; fourth, Mr. Kemp, gardener to Earl Percy, Albury Park.

In the class for two live plants, admirable collections were furnished by Messrs. Lee, of Hammermith; E. Cole & Sons, of Withington, near Manchester; and Mr. Rhodes, Sydenham. Among Messrs. Lee's plants were excellent examples of *Erica ventricosa coccinea* minor, *Azaleas*, *Eriostemons*, *Medulla magnifica*, and *Acrophyllum venosum*, *Aphelaxis macrantha spserba*, splendid in colour; *Adenandra fragrans*, well studded with bloom. Mrs. Cole & Sons contributed excellent specimens of *Heaths*, *Azaleas*, *Aphelaxis*, *Pimelea Hendersoni*, and *IXORA coccinea*. There was also a large plant of *Phaenocoma prolifera* Burnessii, but far from equal in point of bloom to a similar plant exhibited a year or two ago by Mr. Fraser, of Lea Bridge. Mr. Rhodes had the finest plant of *Dracophyllum gracile* in the Show, although by an accident it had lost half a dozen of its white heads of bloom. excellent *Azaleas*, *Eriostemons*, a *Chorozeema*, *Aphelaxis*, *Cavendish Heath*, &c.

Awards—First, Messrs. Lee; second, Mrs. E. Cole & Sons; third, Mr. Rhodes.

Collections of ten were exhibited by Mr. Donald, gardener to J. G. Barclay, Esq., Leyton; Mr. Morse, gardener to T. Canning, Esq., Westbury-on-Trym, Bristol; Mr. A. Ingram, gardener to J. J. Blandy, Esq., Highgrove, Reading; and Mr. Kaile, gardener to Earl Lovelace, East Horsly Tower. Noticeable among the plants from these exhibitors were the lovely *Clerodendron Thomsonae*, *Allamanda cathartica*, *Rhynchospermum jasmuoides*, *Actus gracillimus*, with gay yellow and dark crimson flowers, and not often seen at exhibitions; *Statices*, *Adenandra fragrans*, in fine bloom; *Leschenaultia intermedia*, with showy scarlet flowers; *Pteronia elegans*, but not in full bloom; *Polygala*, *Heaths*, *Azaleas*, and other plants already named.

Awards—First, Mr. Donald; second, Mr. Morse; third, Mr. A. Ingram; fourth, Mr. Kaile.

Collections of six were shown in separate classes, both by amateurs and nurserymen, and comprised among other plants a very fine *Azalea Apollo*, from Mr. Carson; an excellent example of *Pimelea Hendersoni*, from the same; the white and crimson-eyed *Yucca oenata*, from Mrs. Glendinning & Sons; a well-grown plant of *Erica Victoria*, from Mr. Tanton, the successor to Mr. Dods, of the Epsom Nursery; *Clerodendron Kempferi*, *Inuantiophyllum minutum*, *Oxycloium arborescens*, with spikes of yellow pea-like flowers, besides several very good examples of *Pimeleas*, *Rhynchospermum*, *Azaleas*, *Heaths*, *Chorozeemas*, *Genethyllis*, *Eriostemons*, &c.

Awards—For six (Amateurs): first, Mr. Carson, gardener to W. R. G. Farmer, Esq., Nonsuch Park, Chess; second, Mr. Page, gardener to W. Leaf, Esq., Streatham; third, Mr. A. Wilkie, gardener to —McHenry, Esq., Addison Road, Kensington. (Nurserymen): first, Mr. J. Stevenson, Timperley; second, Mr. Williams, Holloway; third, Mrs. Glendinning & Sons, Turnham Green; fourth, Messrs. Jackson & Sons.

For the finest stove or greenhouse plant, in or out of flower, and not less than 12 feet in height, the first prize was awarded to Messrs. Veitch & Sons, for *Brownea erecta* (?); the second to Mr. Williams, for a remarkably fine plant of *Rhopala De Jonghii*, probably not less than 20 feet high; and the third to Mr. Ball, who contributed an *Arancaria exelsa*, 20 feet high; *Aralia quinquefolia*, forming a standard 18 feet high; and *Draecna australis*, 15 feet high. From Mr. Williams came *Draecna draco Barbavi*, about the same height.

Fine-foliaged stove and greenhouse plants were shown in great number, and in point of cultivation they left little to be desired. Mr. Baimes had fine examples of *Alcaesia metallica*, *Theophrasta imperialis*, with ample deep green foliage; *Anthurium grande*, another handsome large-leaved plant; *Rhopala coreovadense*, *Dasy-lirion acrotrichum*, *Gleichenia splenacea*, *Croton variegatum*, *C. longi-*

folium, *Dicksonia antarctica*, with the fronds assuming a somewhat drooping character; *Cordyline indivisa*, and *Aralia leptophylla*. From Mr. Taylor, gardener to J. Yates, Esq., Highgate, came a noble plant of *Sabal Blackburnianum*. Variegated Aloe-leaved *Yucca*, *Dion edule*, two species of *Eucephalartos*, and *Cycas revoluta*. Mr. Fairbairn, Stion House, furnished the Bird's-nest Fern, *Anthurium acule*, with leaves a yard in length, *Alcaesia Lowii*, and others of the same genus, and a large *Draecna*; and Mr. Cross, gardener to Lady Ashburton, Romsey, the pretty *Maranta fasciata*, which has the leaves branched with pale green; *Spha rogyne latifolia*, *Cyperus alternifolius* variegatus, with its white variegation well developed, an *Alcaesia*, and other effective plants. Several fine Palms, including *Areca Yerschuffelti*, *Latania borbonica*, *Astrocaryum rostratum*, the last very graceful, came from Madame Legrelle d'Hanis, of Antwerp. Several magnificent groups were exhibited in the nurserymen's class for twelve. That from Messrs. Lee was particularly good, and comprised a very fine variegated *Croton*, *Theophrasta imperialis*, *Alcaesia metallica*, and *Lowii*, both with fine large leaves; *Rhopala*, *Pandanus elegantissimus*, *Latania rubra*, *Oreopanax dactylofolium*, remarkable for its deeply divided foliage, a handsome plant of *Cibotium princeps*, and a *Cyathus*. Messrs. Veitch also exhibited a fine collection, in which were *Pandanus Veitchii*, resembling an immense fan; *P. reflexus*, *Cycas revoluta*, *Rhopala coreovadense*, *Scaforthia elegans*, a fine plant of *Draecna indivisa lineata*, a large *Croton pictum*, *Scaforthia elegans*, and other Palms. From Mr. Williams came *Alcaesia metallica*, Aloe-leaved *Yucca*, a spreading plant of *Cycas circinalis*, *Crotonas*, *Alcaesia metallica*, *Dion edule*, *Cibotium princeps*, and *Pandanus javanicus* variegatus, all of which were very good. The graceful Fern-like-leaved *Macrandra filifolia*, a Maple with bronzy foliage, *Rhopala*, and other plants already named, came from Messrs. A. Henderson and Co.

In other classes for subjects of the same character, good exhibitions came from Mr. John Stevenson, Lark Hill, Timperley; Mr. Hunt, gardener to Miss Burdett Connt's; Mr. Young, gardener to W. H. Stone, Esq., M.P.; Messrs. Veitch, and Mr. Williams. Among the plants exhibited were *Alphila australis*, *Cibotium princeps* and *Schiede*; *Cyathus dealbata*, and other Ferns; *Alcaesia albo-violacea* with violet-tinged leafstalks edged with white, *A. metallica* with very large leaves, *A. Lowii*, *Draecnas*, *Crotonas*, *angustifolium* being particularly fine; *Pandanus*, *Latanias*, *Cyanophyllum*, *Musa vittata*.

Awards—For twelve (Amateurs): first, Mr. Baimes; second, Mr. Taylor, gardener to J. Yates, Esq.; third, Mr. Fairbairn, gardener to the Duke of Northumberland, Stion; fourth, Mr. Cross, gardener to Lady Ashburton. For twelve (Nurserymen): first, Messrs. Lee; second, Messrs. Veitch; third, Mr. Williams. For six: first, Mr. Stevenson; second, Mr. Hunt; third, Mr. Young, gardener to W. H. Stone, Esq.; fourth, Mr. A. Ingram, gardener to J. J. Blandy, Esq. For twelve tender variegated plants: first, Messrs. Veitch; second, Mr. Williams; fourth, Madame Legrelle d'Hanis.

ECONOMICAL AND MEDICAL PLANTS.—Collections of these came from M. Linden, of Brussels, Mr. Ball, and Messrs. Osborn, who received prizes in the order in which they are named.

HARDY DECIDUOUS SHRUBS IN FLOWER.—From Mr. Turner, Slough, came charming *Weigelas*, both rose and white, *Guedres* *Roses*, variegated *Hydrangea*, the sweet-scented *Philadelphus mexicanus*, *Tree Paeonies* in fine bloom, *Persian Lilac*, &c., and from Mr. William Paul, *Weigela rosea*, *Brooms*, the pink-flowered *Robinia hispida*, *Lilacs*, the common *Berberis*, *Coronilla eburnea*, *Gumper's Thorn*, a new German variety; *Spireas*, *Viburnum plicatum* and *opulus*, and *Dentzia gracilis*. These two collections were placed near the entrance from the Royal Horticultural Society's garden, and attracted much attention.

Awards—First, Mr. Turner; second, Mr. W. Paul.

FINE-FOLIAGED HARDY DECIDUOUS SHRUBS.—Of these there was only one exhibitor, Mr. W. Paul, to whom a third prize was awarded. Noticeable in his collection were a *Horse Chestnut* with the leaves cut into small segments, a *Chestnut* with well-marked golden variegation, the white variegated *Acer negundo*, and another *Maple* in which the leaves were distinctly variegated with pale yellow, a golden-leaved *Elder*, *Purple Beech*, *Quercus cerris* variegata with creamy variegation, *Paulownia imperialis*, *Silver Poplar*, *Aucuba-leaved Ash*, *Magnolia tripetala* and *acuminata*, *Hippophae rhamnoides*, and *Symphoricarpos variegatus*.

HARDY CLIMBERS were shown by Mr. W. Paul, Mr. Turner, and Messrs. Ivory and Son, who were respectively first, second, and third, and consisted of *Clematites*, *Ivies*, plain-leaved and variegated, *Honey-suckles*, *Aristolochias*, *Bigonia grandiflora*, *Climbing Roses*, and *Passiflora cornuta*.

HARDY EVERGREENS.—In the special classes for these were very good examples of new *Aucubas*, *Hollies* in great variety, several kinds of *Box*, *Laurus nobilis*, *Lanrustinus*, *Berberis Darwinii*, *Phillyreas*, *Portugal Laurel*, *Arbutus unedo*, and *Rolissinus*, and *Evergreen Oaks*.

Of new evergreen trees and shrubs Messrs. Veitch contributed *Aucubas*; the lathery-leaved *Raphiolepis ovata*, a great acquisition both as regards flowers and foliage; *Skimmia oblata*; a golden variegated *Enonymus japonicus*, one of the many pretty Japanese introductions; *Enonymus radicans* variegatus; *Hlex Fortunei*; the Holly-leaved *Osmanthus*, and a dwarf variegated form of it; *Ternstroemia* species, and a variegated *Ligustrum glabrum*. Mr. Standish had, in addition to several of the above, *Skimmia fragrans*, the tall

and dwarf forms of the variegated *Osmanthus ilicifolius*, and *Ligustrum coriaceum*. Mr. Bull's collection consisted wholly of new *Aucubas*, male and female.

Awards—For twenty: first, Messrs. Jackman & Son; second, Mr. Standish; third, Messrs. Lee. For twelve (New): first, Messrs. Veitch; second, Mr. Standish; third, withheld; fourth, Mr. Bull.

ALPINE AND HEIBRACIOUS PLANTS.—Messrs. Backhouse, of York, exhibited a charming collection of Alpines, many of them very interesting, and Mr. Salter one of variegated plants, consisting of *Funkias*, *Sedums*, *Colt-foot*, *Arabis*, *Aubrietia*, &c., to the number of fifty. Both of these collections excited much interest, especially that of Messrs. Backhouse, which seemed to be a particular favourite with the ladies. First prizes were awarded to both exhibitors.

ORCHIDS.—The tent in which these were exhibited was continually crowded—so much so, that it was not without difficulty and by the exercise of considerable patience, that they could be approached. This fact is sufficient to prove that they excited no small amount of interest, and they were well worthy of it, for nearly all the most ornamental genera were well represented; and though the number of collections fell rather short of what might have been expected in a country like this, where there are so many cultivators of this beautiful tribe of plants, still they were sufficient to fill an extent of 400 feet in length. The only exhibitor in the class for fifty was Robert Warner, Esq., of Broomfield, Chelmsford, who sent numerous varieties of the beautiful *Cattleya Mossie*, several of them remarkable for the size of the blooms and their richness of colour; also *Vanda tricolor* with three fine spikes; its variety *superba* deeper and richer in colour, and with a bright purplish crimson lip; and *V. snavis*, remarkably fine. Of *Trichopilia crispata* there was one of the finest examples we remember to have seen, bearing at least a score of finely coloured flowers. *Phalenopsis* were well represented by *P. amabilis*, *grandiflora*, *Schilleriana*; and *Portel*, white, with a rosy purple lip, was very full of bloom. Of *Chysis Limminghii*, *Cypripedium barbatum superbum*, C. Hooker, *C. villosum*, and *C. hiruttissimum*, there were good examples, as well as of *Lælia cinnabarina purpurata*, and *Schilleriana*, the Fox-brush *Acrides*, and *Dendrobium nobile*.

In a collection of twenty from Mr. Bullen, gardener to A. Turner, Esq., Leicester, were a fine pot of *Cypripedium barbatum superbum*, with fifty blooms, *Odontoglossum Pescatorei*, *Cattleya Acklandia*, and *Skinneri*, the latter very fine; *Dendrobium Parishii*, *Brassia verrucosa* a yard across; *Lælia purpurata*, and a remarkably fine specimen of *Oncidium ampliatum majus*. From Mr. Page, gardener to W. Leaf, Esq., came *Vanda teres* with five good blooms, *Phalenopsis amabilis*, *Oncidium flexuosum*, and *ampliatum majus*, with three long spikes, *Saccolabium Blumei*, with a spike about 15 inches in length, and *Dendrobium anosmum*, with six good spikes; and Mr. Peed, gardener to Mrs. Tredwell, sent good *Acrides*, *Cypripedium*, *Oncidium sessile*, with clear yellow flowers, *Vandas*, *Dendrobiums*, and a highly coloured variety of *Lælia purpurata*. Mr. Cullen, gardener to W. Wentworth Buller, Esq., Strete Raleigh, exhibited *Cypripedium*, or as it is called by some botanists *S-lepidium*, caudatum with two large blooms, having "tails" nearly 2 feet long; *Uropidium Lindenii*, another Orchid having smaller though shorter appendages; the beautiful new *Phalenopsis Luddemanniana* with three blooms; a branching specimen plant of *Oncidium bifolium*, with large blooms; the white-flowered *Burlingtonia fragrans*, *Cypripediums Lowii* and *barbatum*, and *Cattleya Acklandia*, none of them large, but all well grown. Mr. Robson, gardener to G. Cooper, Esq., Old Kent Road, also furnished a collection, in which we noticed *Acrides crispum*, with a good spike upwards of a foot in length, and several *Oncidium*s.

In the Nurserymen's Class for twelve, Messrs. Veitch had a superb example of *Cypripedium barbatum majus* with about fifty blooms; *C. villosum* with about thirty flowers; *Saccolabium guttatum* with remarkably fine long spikes; a splendid *Lælia purpurata*, *Odontoglossum Pescatorei*, one of the most beautiful of the family, and *O. navium*, each with about a score of flowers; *Cattleya Mossie* elegant, and *Vanda tricolor superba*. In the collection from Mr. Williams were *Phalenopsis Luddemanniana* with six blooms; and *P. grandiflora*; *Vanda teres*, richly coloured; a noble plant of *V. insignis*; *Cypripedium Stonei* with four fine blooms; *C. barbatum superbum*, very fine; splendid *Cattleyas*; and a very good *Saccolabium retusum*. Among Mr. Bull's twelve were *Cypripedium caudatum*, and the yellow Tulip-like *Angolan Clowesii*.

In the Amateurs' classes excellent exhibitions came from Mr. Penny, gardener to H. H. Gibbs, Esq., Regent's Park; Mr. Wilson, gardener to W. Marshall, Esq., Enfield; Mr. Howard, gardener to J. Brand, Esq., Bulham; and Mr. Fairbairn, Sion House. Among the plants exhibited were remarkably fine examples of *Trichopilia crispata*, *Phalenopsis grandiflora*, *Dendrobium anosmum*, *D. Dalhousianum*, *D. densiflorum album*, and *D. nobile*; *Saccolabium*s, *Cattleyas*, *Lælias*, *Oncidium sarceodes*, *Cattleya Acklandia* with eight richly coloured flowers; and, lastly, *Cypripediums*, particularly *caudatum*, one of which from Mr. Wilson, had nine flowers with petals 2½ inches long, by far the finest specimen shown of that handsome species.

Awards—For fifty: first, R. Warner, Esq. For twenty: first, Mr. Bullen; second, Mr. Page; third, Mr. Peed; fourth, Mr. Cullen. For twelve (Nurserymen): first, Messrs. Veitch; second, Mr. Williams; third, withheld; fourth, Mr. Bull. For ten: first, Mr. Penny; second, Mr. Wilson; third, J. Stevenson, Esq.; fourth, Mr. Wheeler, gardener to J. Philpott, Esq., Stamford Hill. For six: first, Mr. Howard;

second, Mr. Fairbairn; third, Mr. Young, gardener to W. H. Stone, Esq., Havant; fourth, Mr. A. Ingram, gardener to J. J. Blundy, Esq. For six (Nurserymen): first, Messrs. Lee; second, Mr. Rhodes; third, withheld; fourth, Messrs. Jackson & Sons.

In new Orchids, the first prize was awarded to M. Linden, of Brussels, for *Acrides japonicum* with greenish white sepals and petals barred with rose, and having rose markings in the lip; the second, to Messrs. Veitch, for *Anguæum citratum* with small white flowers having a slight lemon tinge, closely set on what, for a new Orchid, was a long spike. Messrs. Backhouse sent *Oncidium concolor* with large yellow flowers; Messrs. Veitch, *Cypripedium lavigatum*, a very ornamental species; Mr. Williams, *Vanda cristata superba*; Mr. Warner, *Cattleya Mossie Mariana*, a very beautiful variety; also, *Trichopilia crispata marginata*, in which the flowers are bordered with white. A fine variety of *Miltonia spectabilis*, and *Dendrobium taurinum*, were shown by J. Bateman, Esq., of Baldolph Grange.

For the best specimen Orchid, the first prize was awarded to Mr. J. Charles, gardener to R. Barnett, Esq., Blackheath Park, for *Phalenopsis Luddemanniana* with nine blooms, some of which were exceedingly fine. The second prize went to Mr. Cullen, for a good *Phalenopsis amabilis*; the third, to Mr. Bullen, for an immense plant of *Dendrobium nobile*, measuring some 4 feet across and in fine bloom; and the fourth, to Mr. Webb, gardener to J. W. Miles, Esq., Kingsweston, for *Ansellia africana* with three fine spikes.

Miscellaneous Orchids comprised *Phalenopsis Luddemanniana* with four fine blooms; *Trichopilia tortile*; *Aspsia lanata* with a white lip, and the sepals and petals green, marked with brown; a very handsome and compact specimen of *Dendrobium densiflorum*, *Saccolabium guttatum splendens*, and some others, from Mr. Wilson, gardener to W. Marshall, Esq.; and *Acrides virens* and a few others were shown by Mr. Parker, of Tooting.

Of variegated Orchids, Mr. Williams contributed a fine collection, in which *Phalenopsis Schilleriana* was conspicuous, besides which (*Goodyera discolor*, *Anectochilus petala*, *Lowii*, *setaceus*, *anthophyllus*, and others of the same beautiful genus were in great perfection. A first prize was awarded to Mr. Williams, and a third one to Mrs. Glendinning and Sons.

Before concluding our remarks on the Orchids it is but an act of simple justice to Mr. Ormsom to state that the whole of the immense tent in which these are exhibited is heated by him, free of charge, by one of his new wrought-iron multitubular boilers; and to give an idea of the magnitude of this undertaking, we will mention that 3200 feet of pipe and 1760 gallons of water are employed to heat 400,000 cubic feet of air, and this, be it remembered, not in a glass structure, but in a tent, through the walling of which the keen east winds which we have lately experienced have been continually finding their way.

PALMS.—In the classes specially devoted to these there were fine examples of *Phoenix dactylifera*, *Lantana borbonica*, *Verschaffelti*, and *Jenkinsii*, *Thrinax elegans*, *Corypha australis*, *Chamærops hamilis*, and *exelsa*, *Seuferthia elegans*, the Oil Palm, the noble *Stevensonia grandifolia*, or *Phoenixophorium sechellarum* as it is also called, the *Coccol-nut*, *Arecas*, and *Astrocaryum mexicanum*; and many others were scattered through various classes.

Awards—For six: first, Mr. Fairbairn, gardener to the Duke of Northumberland, Sion; second, Messrs. Veitch; third, M. A. Verschaffelt, Ghent. For three: first, Mr. Williams; second, Messrs. Jackson & Son; third, Mr. Bull. For the largest and finest: first, Mr. Young, gardener to R. Barclay, Esq., Highgate; second, Mr. Bull; third, Mr. Williams.

CYCADS.—M. A. Verschaffelt received the first prize for *Zamia cyclophobii*, *Z. cæfra* with a trunk 15 inches in diameter, and *Z. Verschaffelti*. Mr. Taylor, gardener to J. Yates, Esq., Highgate, who was second, had fine plants of *Cycas revoluta*, *Zamia cæfra*, and *Z. muricata*; and Mr. Williams, Holloway, was third with *Dion edule*, *Cycas revoluta*, and *Zamia pungens*. Among those from Mr. Bull was *Cycas Ruzmianina*, a slender-stemmed kind from the Philippines.

PANDANUS.—Among these we noticed remarkably fine specimens of *Pandanus javanicus variegatus*, *P. ornatus*, and *P. elegantissimus* from Messrs. Veitch; *Freycinetia imbricata*, and *Pandanus utilis*, and *reflexus* from Mr. Williams; and Messrs. Jackson sent *Pandanus imbricatus*, *candelabrum*, and *javanicus variegatus*. A fine specimen of *Pandanus utilis* came from Messrs. Veitch; and Mr. Young, gardener to R. Barclay, Esq., and Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, respectively sent *P. elegantissimus* and *P. javanicus variegatus*.

Awards—For three: first, Messrs. Veitch; second, Mr. Williams; third, Messrs. Jackson and Sons. For a single specimen: first, Mr. Young; second, Mr. Donald; third, Messrs. Veitch.

FERNS AND LYCOPODES.—The grand tree Ferns exhibited by Mr. Williams, the in-door Plant Superintendent at the Crystal Palace, formed conspicuous objects from every part of the Exhibition. They consisted of three plants of *Cyathea medullaris*, two of *Dicksonia antarctica*, and two of *Cyathea dealbata*, averaged 24 feet in height, and had spreading heads about 16 feet in diameter. The largest specimen of *Cyathea medullaris* was magnificent, being no less than 30 feet high. Of stove and greenhouse Ferns several admirable collections were exhibited by Mr. Williams, Mr. Baines, Messrs. Veitch, Mr. Bull, and others, containing fine examples of *Cibotium princeps*, *Schiederi*; *Dicksonia antarctica*; *Gleichenia semivestita*, *flabellata*; *Alsophila australis*; *Cyathea medullaris*, *dealbata*, and *Cooperi*; *Platy-cerium grande*, *Marattia elegans*, *Lomaria gibba*, *Blechnum corco-*

vadense, *Todea africana*, *Pteris scaberrima*, the beautiful *Leptopteris superba*, *Trichomanes radicans*, *Pteris erecta albo lineata*, *Drynaria morbillosa*, and many others which it would be tedious to enumerate. Hardy Ferns were of a numerously shown. Those from Messrs. Ivory and Son, and Mr. Marshall, of Enfield, were well worthy of notice. The latter gentleman had a fine plant of *Trichomanes radicans*, *Athyrium Filix-femina crispum*, a very pretty variety of the Lady Fern, *Scopolopodium vulgare multifidum*, A. F. Fieldingii, a nice plant of *Polypodium dryopteris*, and the pretty *Polypodium alpestris flexile*, and *Hymenophyllum umbriferum*. Messrs. Ivory exhibited two collections, the plants composing one of which were dotted over the rockwork at the Crownwell Road end, where they had a charming effect; and in another were many interesting varieties of *Athyrium Filix-femina*, such as *Frizolii*, *plumum*, *Fieldii*, *multiceps*, and *Applayanum*, several *Polystichums*, *Struthiopteris germanica*, and a nice case of *Trichomanes radicans*. Mr. Salter and Mr. Bull also furnished good collections.

Of new Exotic Ferns, Messrs. Backhouse and Messrs. Veitch exhibited a few, among which were an *Asplenium* from New Caledonia, *A. androphylum*, *A. rosetatum*, *Davallia alpina*, and *Trichomanes fomiculaceum* from Java.

New Hardy Ferns, shown by Messrs. Ivory, consisted of *Trichomanes Moolle*, small but pretty; *Polystichum angulare attenuato-erectatum*, slender and but slightly crested; *Lastrea Filix-mas Ingramii*, a hard some vigorous variety; and *A. F. laccolatum*, with pretty tapering bright green fronds, all of which received first-class certificates, and one of the second class was awarded to *A. F. pterophorum*.

Of Lycopods, beautiful pans were shown by Messrs. Veitch, Mr. Barnard, gardener to J. W. Taylor, Esq., Stoke Newington, and Mr. Fairbairn, Sion; and the following kinds were particularly worthy of notice:—*viz.*, *Selaginella Martensii variegata*, beautifully variegated with white; a pendulous species from the Solomon Islands, bearing a striking resemblance to a *Draacrydium*; *Japonica*, of a fine deep green; *Japonica variegata*, *ensata*, *umbrosa*, *erythronum*, *spoda*, *Galeotti*, *Wildenowii*, *denticulata*, *stolonifera*, and *rubiculosa*.

Awards.—For twelve stove-glass greenhouse Ferns (*Anatensis*): first, Mr. Baines; second, Mr. J. Hill, gardener to R. Hanbury, Esq., The Poles, Ware; third, Mr. Barnard. For twelve (*Nurserymen*): first, Mr. Williams; second, Mr. Bull. For six (*Anatensis*): first, Mr. Young, gardener to W. H. Stone, Esq.; second, Mr. Cross; third, Mr. Wilson, gardener to W. Marshall, Esq.; fourth, Mr. A. Ingram. For six (*Nurserymen*): first, Messrs. Veitch; second, Messrs. Jackson & Sons. For six new Tender Ferns: first, Messrs. Backhouse; second, Messrs. Veitch; third, Mr. Williams. For six new Hardy Ferns: first, Messrs. Ivory; second, Mr. Bull; third, Mr. Williams, Holloway. For twenty-four Hardy Ferns: first, Messrs. Ivory; second, Mr. Salter; third, Mr. Bull. For twelve: first, Mr. Wilson; second, Mr. Kille; third, Mr. Kemp, gardener to Earl Percy. For six Tree Ferns: first, Mr. Williams, Crystal Palace; second, Messrs. Veitch; third, Mr. Williams, Holloway. For three: first withheld; second, Mr. Bull; third, Mr. Hill, gardener to Miss Burdett Coutts. For the finest Tree Fern: first, Mr. Williams, Crystal Palace; second, Messrs. Veitch; third, Mr. Bull. For twelve Lycopods: first, Mr. Barnard; second, Mr. Fairbairn; third, Mr. Higgins, gardener to Mrs. Barchard, Putney Heath. For six: first, Messrs. Veitch; second, Mr. Young, gardener to R. Barclay, Esq., Highgate.

ARADS, ARALIADS, AND MARANTADS.—For Arads, Messrs. Veitch were first with *Dickknechtia variegata*, *Baranquiniana*, *Alocasia longiloba*, the handsome *Loddii*, *Veitchii*, *macrorhiza variegata*, and *zelrina*, and *Aglaiomona commutatum variegatum*. Madame Legrelle d'Hanis and Mr. Williams also contributed good specimens. Messrs. Veitch also exhibited several very handsome Araliads, and a fine collection of Marantads, consisting of the beautiful *Maranta Veitchii*, *zelrina*, *striata*, *splendida*, *regalis*, *Van den Heckii*, *tubispata*, very handsome, and some others. Among those from Madame Legrelle d'Hanis, who was second, were *M. arata*, *roseo-lineata*, and *Phytium Van den Heckii*.

DWARF CACTI.—Nice collections of these came from M. Charles Piersard, of Knsal Green and Avenue de St. Ouen, Paris, in which were *Echinocactus Cunninghamii* with orange flowers; *Echinopsis Eyre* in full with large pink flowers; *Echinocereus multicaudatus* with scarlet blooms. Several very curious kinds of *Cereus*, *Mumiliarias*, *Echinocactus*, and similar subjects were shown by W. B. Kellock, Esq., Stamford Hill; Mrs. Pattison, Dorchester; and Mr. Waters, gardener to A. Mongredien, Esq., Forest Hill.

HARDY TAXADS.—For these Messrs. Veitch were first with a fine collection, in which were *Taxus japonica*, like a broad-leaved Irish Yew; *T. fastigiata*, of fine pyramidal growth; a handsome bushy plant of *Cephalotaxus drupacea*, *Artiplexis selaginoides*, *Cephalotaxus Fortunei*, and *Taxus depressa* with deep green foliage. Messrs. Waterer & Godfrey, who were second, had *Podocarpus andina* with dark foliage, *Taxus baccata erecta*, *aurea*, *elegantissima*, and *fastigiata*, along with some others; and a third prize was awarded to Mr. Wm. Paul.

CONIFERS.—The hardy species and varieties were numerously shown, and among them were many handsome specimens though necessarily not large. The best collection of twenty-five came from Messrs. Veitch, and comprised *Larix Kamptsi*, a pretty light green species; handsome *Pinus peisii*; *Thuja japonica*, forming a close pyramidal plant; *Thujaopsis borealis* and *dilatata*. Messrs. Waterer & Godfrey, who were second, had *Thuja filiformis* of varying habit, *Lobbi*, and *aurea*; *Pinus inaequalis*, and others. We also noticed in collections from the above and other exhibitors, *Cupressus Lawsoniana*, and a handsome variegated variety of it called *argentea*; *Fitzroya patagonica*; some fine plants of *Thuja aurea*; several interesting dwarf varieties of *Abies excelsa*, such as *Cambasiana*, *pumila*, *Gregorii*, and *pygmaea*; *Juniperus libanica compressa*, which would form a useful plant for flower-garden beds, &c. Messrs. Jackson contributed fine examples of *Picea Nordmanniana*, *P. pinusapo*, *laeocarpa*, *nobilis*; *Thuja gigantea*, and *Wellingtonia*, both handsome plants about 8 feet high; *Cupressus Lawsoniana*, and others, which were studied over the rockwork near the southern entrance; whilst at various parts of the tent Messrs. Lee, Paul & Son, Standish, and others, exhibited the same class of subjects, the collection from Messrs. Paul & Son, not shown for competition, being very extensive. The only exhibition of

Greenhouse Conifers was that of Mr. Bull, consisting of *Arancaria excelsa*, *Bidwillii*, *Cookii*, *Cunninghamii* and its variety *glauca*, and *Libocedrus Domiana*.

Awards.—For twenty-five Hardy Conifers: first, Messrs. Veitch & Sons; second, Messrs. Waterer & Godfrey; third, Mr. J. Standish. For twelve: first, Messrs. J. & C. Lee; second, Messrs. Jackson & Son; third, Mr. C. Turner. For twelve Greenhouse Conifers: first, Mr. W. Bull.

CALAEADS, BEGONIADS, AND ANTIPIUMS.—The first were well represented in collections from Mr. Goodwin, gardener to A. Wattenbach, Esq., Camberwell; Messrs. A. Henderson & Co. and Mr. Fairbairn, who stood in this order in the prize list. *Chautau*, *Wichiti*, *Belleme*, *Indolor splendens*, and the pretty *argyræa* were a few of the best. In *Begonia*, well-grown plants from Mr. Smece, Mr. Wheeler, and Mr. Vanner were awarded prizes; and for *Begonia* in flower Mr. Earley, gardener to F. Fryer, Esq., Digswell, received a first prize. The most noticeable was *Dischidandra*, a very useful free-flowering deep rose-coloured sort. For *Anthurium*, Messrs. Veitch were first, Mr. Williams second, and Messrs. A. Henderson & Co. third. *Anthurium Scherzerianum* from the Messrs. Veitch had nine of its brilliant scarlet spathe of the largest size; and the same beautiful species was shown in fine condition by Mr. Williams, who also had several producing its singular inflorescence. *A. cordifolium* was likewise shown in great perfection.

NEPLENTES AND SARACENIADS.—Of the former admirable examples were exhibited by Messrs. Veitch, consisting of *Dominiana*, *Hookeri*, *laxis*, *phyllanthora*, an unnamed species, and *Rafflesiana*, with three pitchers. For these a first prize was awarded, also for a remarkably fine single plant of *Rafflesiana*. Excellent *Sarracenia* came from Mr. Baines and Mr. Williams, who were placed first and second.

YUCCAS, BEACARBENAS, AND DASYLIRIADS were exhibited by Mr. Williams, M. Jean Verschaffelt, W. B. Kellock, Esq., Stamford Hill, and Mr. Bull. *Yuccas* consisted of *quadricolor*, the variegated Aloe-leaved kind, *Stokesii*, and *albo-specta*; among *Beacarbenas* were *stricta*, *recurvata*, and *glauca*; and among *Dasyliriums*, *aerotrimum latifolium*, *longifolium*, and *Hartwegii*.

Awards.—First, Mr. B. S. Williams; second, M. Jean Verschaffelt; third, W. B. Kellock, Esq., Stamford Hill; fourth, Mr. Bull.

DRACENAS AND CORDULINES.—Among these were some noble specimens of *C. hibernifolia* and *indivisa*, *an-tralis latifolia*, *Dracena draco*, *indivisa*, and such kinds as *Cooperi*, *farica variegata*, and *nigricans*, with finely coloured foliage.

Awards.—First, Messrs. Veitch & Sons; second, Mr. Williams; third, Messrs. Jackson & Son; fourth, Mr. Bull.

AGAVES were numerously shown, and asserted well with the rockwork near which they were placed. Noticeable among them were *Schidzera*, with the margins of the leaves set as it were with wood shavings; *filifera*, and its variety *longifolia*; the common and variegated American Aloe, the latter variously striped, in one of its varieties having a broad golden band up the centre of the leaf; *pieta longifolia*, broadly margined with cream colour; *caruleasens*, with very very dark foliage, and *decalata*, with long pale green leaves, having a glaucous tinge. *Verschaffeltii*, with handsome foliage; *Ousselghemiana*, pale green; *Jacobiana*, with broad leaves set with purple spines, and many other singular kinds came from M. J. Verschaffelt, of Ghent.

Awards.—For twenty-four: first, M. J. Verschaffelt; second, Mr. Williams; third, M. Charles Piersford. For ten: first, Mr. Williams; second, M. J. Verschaffelt; third, W. B. Kellock, Esq., Stamford Hill.

STANDARD ORANGE TREES, BAYS, PORTUGAL LAURELS, &c.—The first were not remarkable for size, but several finely fruited plants were shown by Messrs. Osborn and Bull. There were also the standard *Myrtles*, *Bays*, and *Laurustinus* from the last-named exhibitor; but the best pair of standard Bays came from M. Jean Verschaffelt; of *Portugal Laurels*, from Messrs. Lee; and of *Box*, from Messrs. Veitch. These stood about 7 feet high, and had handsome round heads. The same firm had also a pair of *Waterer's* variegated Holly 9 or 10 feet high; and Messrs. Waterer had the same variety, though not so tall. The finest, however, came from Messrs. Jackson, of Woking, and had stems 5 or 6 feet high, and heads measuring at least as much across. Several good standard Yews were also shown, as well as large-headed *Portugal Laurels*, the latter by Messrs. Lee.

Awards.—One *Orange tree*: second, Mr. Bull; third, Messrs. Osborn and Sons. Twelve *Orange trees*: third, Mr. Bull. One pair of standard *Laurustinus*: first, Mr. Bull. One pair of pyramidal *Bay trees*: first, Messrs. Veitch; second, Mr. Bull; third, Messrs. J. & C. Lee. One pair of standard *Bay trees*: first, M. J. Verschaffelt; second, Messrs. Veitch; third, Messrs. J. & C. Lee. One pair of standard *Portugal Laurels*: first, Messrs. J. & C. Lee. One pair of standard *Hollies*: first, Messrs. Jackson and Son; second, Messrs. Veitch & Sons; third, Messrs. Waterer & Godfrey. One pair of standard *Box trees*: first, Messrs. Veitch & Sons; second, Messrs. J. & C. Lee. One pair of any standard evergreen: first, Mr. Bull; second, Messrs. Veitch & Sons; third, Messrs. J. & C. Lee.

HOLLIES were shown in great variety, and some of them were very pretty. *White and Golden Milkmaid*, *Chapman's* *Gold-striped*, *Gold and Silver*, *Hedgehog*, *Gold-edged*, having dark and young shoots, were some of the best of the variegated kinds. Of the plain-leaved *Box cornuta*, *Hogkinnii*, with large dark foliage; *scotica*, very dark, and *myrtilifolia*, with small dark green leaves, were amongst the most noticeable.

Awards.—For thirty: first, Messrs. Veitch & Sons; second, Messrs. Waterer & Godfrey; third, Messrs. J. & C. Lee.

New Plants, chiefly remarkable for their foliage were numerously shown. *M. Linden*, of Brussels, was first and third for six introduced into Europe by the exhibitor; and Messrs. Veitch & Sons second and fourth. These from the former, to which the first prize was awarded, were *A. Lurum regale* with leathery green leaves, with distinct midribs and venation; *Cyclophyllum spectabile*, with the leaves more oblong than those of *C. maculatum*; *Maranta Lindenii*, with beautifully shaded foliage, the under part very prominently lined; *Bignonia ornata*, with handsome cross green leaves irregularly marked with white; *Philodendron Lindenii*, with handsome cordate foliage; and *Dichorisandra musica*, beautifully marked with numerous white lines. Messrs. Veitch were second with a handsome *Aralia* from New Caledonia; *Maranta Veitchii*; *Rhododendron Brookianum*; *Aedya phalaena*, with ovate brownish-green leaves and some reddish markings; a pretty *Aphelandra*, from Peru, distinctly banded with yellow; and *Briceana albo-marginata*, pale green, edged with golden yellow.

Among other plants from the same firm were a handsome golden variegated *Croton*, quite distinct from the older kinds in the form of its leaves; a pretty *Aralia* with footstalks exhibiting some yellow and crim-

son markings; and Phyllanthus variegatus with green leaves variegated with white. Psychotria nivosa with singular white flowers came from M. Linden.

For three new plants in flower, Messrs. Veitch were first with Begonia Pearcei, with velvety dark green leaves and bright yellow flowers; Palava flexuosa, and an Aphelandra. Mr. Bull was second with Siphocampylus fulgens, with bright scarlet flowers; Bertolonia margaritacea; and an Australian Mallow.

The next class was for one new plant in flower. Here M. Linden was first with the Pseuderanthus above-mentioned to Mr. Standish second with double Clematis Fortuna; Messrs. Veitch third, with *P. Darwinii*.

For a new plant not in flower, M. Linden was first and equal second with Dichorisandra muscicola, and *M. ranta Lindeni*; Messrs. Veitch being equal second and third for the Peruvian Aphelandra and *Maranta Veitchii*; and Mr. Standish equal third for a pretty Aethiopian from Japan. Mr. Bull exhibited a variety of *Passia grandifolia* with variegated leaves; and *M. Ambrasia Verschafflii*, *Zinnia villosa*.

In the class for twelve new plants, Messrs. Veitch were first with the beautiful rose-spotted *Bertolonia gottata*, *Primula cortusoides amana*, *Coleus Gibsonii*, from New Caledonia; an *Araucaria*, the new *Aphelandra*, and some other plants already noted. M. Linden, who was second, had *Dichorisandra vitata*, *M. ranta virginiana*, *M. roseopicta*, *Scindapsus pictus*, *Philodendron Lindeni*, Mr. Bull being among others, *Eranthemum argyreum*, and two pretty variegated *Crotophaga*, whilst Mr. Williams, who received a third prize in the class for six new plants, had an ornamental *Calamagrostis*, called *Impatiens Mariei*, *Teliumia* in the order; and a beautifully variegated New Zealand Flax.

MISCELLANEOUS.—Concerning a young such subject were several plants of *Eucharis amabilis* shown by Mr. Howard, gardener to E. Brand, Esq., Batham. These were in tubs, and measured not less than 5 feet across, though it was stated that but two and a half years ago they had been purchased in three-inch pots. The flowers were of remarkable size, and it was stated that the plants had bloomed three times since Christmas. The course of treatment pursued was to keep them airy with bottom heat in the stove, to ripen when necessary, and afford liberal supplies of manure water. A small collection of Canadian plants from Mr. Stark, Trinity, near Edinburgh, and variegated *Malva* from Messrs. Carter & Co. were shown near these, and at the base of the rock were *Lilies of the Valley* by Mr. Silber and Messrs. Veitch, those from the former having been beautifully striped. A new *A. variegata*, *Woburniana* came from Mr. R. H. Hort and Cork and an *Abies* from Mr. Veitch, the pretty *Eberharts stemonchyla*, and a new *Thymus* from Messrs. Fisher, Holmes, and Co. Mr. Wilson, St. Albans, sent a dozen *Filix Ferns*, several of which were very fine; Mr. Burnett, gardener to J. Taylor, Esq., a number of aquatics, such as *Vallisneria spiralis*, *Apongeton distachyon*, and *Limnocarum Humboldtii*; and Mr. B. B. H. C. O. de P. *Andropogon*, a hybrid *Ananarthus* with very ornamental foliage, totally distinct in character from *A. melancholios ruber*, and which promises to be useful. Miscellaneous groups of plants were exhibited by Messrs. Veitch, Linden, Lee, and E. G. Henderson. That from Mr. Standish including the pretty new variegated *Crotophaga*. Mr. Bull had the *Long-stemmed Radish*, *Pitcairnia tabularifera*, variegated *Malva*, *Maranta piperita*, the singularly marked *Dioscorea amabilis*, *Godenia discolor*, of which the white midribs formed a row. In contrast to the rest of the dark velvety leaves, *Eranthemum argyreum*, and many other interesting plants. From Messrs. Lee came *Andropogon* and *Andros*; from Mr. Wilson, gardener to W. Marshall, Esq., the *Madagascar* *Leucanthemum*; and from Messrs. E. G. Henderson & Son a number of handsome-fangled soft-wooded plants. A very interesting exhibition being the *Ailanthus glandulosa* with the silkworm peculiar to that tree feeding on its leaves, together with specimens of the silk, came from Lady Dorothy Nevill.

BOUQUETS, AND OBJECTS OF ORNAMENT IN NATURAL FLOWERS.

THIS week we can do no more than enumerate the prizetakers in each class, but we propose to do so week by week in our details.

DINNER-TABLE DECORATIONS.—First, Mr. Forman, Knighton, Finchley. Second, Messrs. Lucking, Westbourne Park, W. Third, Mr. T. Charles March, Ambassador's Court, St. James's Palace.

TABLE D'EAU.—Second, Mr. P. A. White, 15, Bedford Place, E. Third, Mr. Deary, 10, St. Andrew's Street, E. First, Mr. T. Charles March, Ambassador's Court, St. James's Palace.

DRAWING ROOM PLANT CASE.—First, Mr. George Macintosh, Nurseryman, Hume Smith. Second, Messrs. Cludet, Houghton, St. Leon, 8, High Holborn. Third, Messrs. Barr & Sazden, King Street, Covent Garden. WINDOW BOX.—First, Messrs. Wm. C. Boush & Son, Nurserymen, Highgate.

HANGING PANSY.—Second, Messrs. Wm. C. Boush & Son, Nurserymen, Highgate. ONE WEDDING BOUQUET.—First, Messrs. Lucking, Westbourne Park, W. Second, Mr. John Belgrave, Nurserymen, Holm Lane, Otton, Cheshire.

THREE BOUQUETS FOR BALUS.—First, Mr. Richard S. Yates, Sale, Cheshire. Second, Messrs. Lucking, Westbourne Park, W. THREE HEAD-DRESSES OR WREATHS.—Second, Mr. Richard S. Yates, Sale, Cheshire.

FRUIT.

THE show of Fruit was not so extensive as might have been expected on such an occasion—a result doubtless attributable to the early period of the season. The quality, however, was generally good. The only collection of ten dishes was that from Mr. Turner, of Slough, which consisted of two good Pines, *M. Jans*, very good bunches of Black Hamburgh and Muscat Grapes, *Cross Mignonne*, *Peaches*, *Hunt's Tawny Nectarine*, *Strawberries*, and *Figs*.

PINES were few in number, but to make up for this deficiency, several were very good. In Queens, Mr. C. J. non, gardener to the Duke of Richmond, was first with a very good fruit; Mr. Carr, gardener to the Rev. J. Micklethwait, Norwich, second; and Mr. Higgs, gardener to Mrs. Burchard, Putney Heath, third. In Smooth-leaved *Cayenne* a fine fruit from that veteran Pine-grower Mr. Borne, gardener to Lady Belle Pierson, was first, and a very good one from Mr. Cameron's second. In the class for a first prize. In the class for any kind, a Smooth-leaved *Cayenne* of 7 lbs.

from Mr. Page, gardener to W. Leaf, Esq., was first, but it was over-ripe at the base, and not sufficiently ripe towards the crown; Mr. Wallis, gardener to J. Dixon, Esq., 4th Park, second with Black Prince, weight 1 1/2 lbs.; and Mr. Drevitt, gardener to Mrs. Cabitt, Dobbies, third with Black *Juniper*.

GRAPES.—In the class for five varieties, Mr. Bannerman, gardener to Lord Ragot, Bitchfield, was first with Golden Hamburgh, Black Hamburgh, and *Chasselas Musque* very well coloured, Black Prince, and Black *Tenerife*. Mr. Allport, gardener to R. Ashford, Esq., Dodington Park, was second with Muscat Hamburgh, Black *Foxtail* from West St. Peter's, Inzuan; *Profile Muscat*, and Black Hamburgh. This was also a nicely coloured collection, and the berries were of size. Mr. Osborne, Kay's Nursery, Finchley, who was third, had, among other, very good bunches of Black Hamburgh and Buckind Sweetwater.

In the class for six bunches Mr. Hill, gardener to R. Sneyd, Esq., Keele Hill, was first with six fine bunches of Black Prince, well coloured, and measuring about 1 1/2 inches from the stalks; the points still green, but not quite to the splendid bunches of this variety which he usually exhibits. Mr. Osborne was second with large bunches of Black Hamburgh not quite perfect in colouring; and Mr. Bannerman third with good bunches nicely coloured, but smaller in bulk. In the same class Mr. Turner exhibited good *Muscats*, but not quite so good; Mr. Gannett and Mr. Wallis excellent Black Hamburghs; Mr. W. Henderson, gardener to Sir G. Beaumont, Bart., Coleorton, very good bunches of the same kind and of Golden Hamburgh.

In Black Hamburghs, three bunches, the exhibitors were un-nominal, and generally very good. Mr. Allport was first and Mr. Turner second with large bunches well coloured; Mr. M. Henderson third with well-grown and nicely coloured bunches. Good exhibitions in the same class came from Mr. Wallis, Mr. Allen, gardener to Capt. Glegg, Mr. Clement, Mr. Bannerman, and J. Tomita, Finchley.

For three bunches of any other Black Muscat coloured Grape, Mr. Allport was first with Black *Foxtail*, two of the bunches handsomely shouldered; Mr. Miller, gardener to Lord Foley, second with the same kind, and Mr. Fowler, gardener to the Earl of Star, Castle Kennedy, third with Muscat Hamburgh.

In the class for three bunches of any other Black kind, Mr. Hill was first with Black Prince; Mr. Allport second with West St. Peter's, and Mr. Crickshank, gardener to W. Jones Lloyd, Esq., third with fine bunches of Black Prince, but scarcely sufficiently coloured.

Muscats, as usual at this season, were not in the state of ripeness that they are seen at a later period, but better in this respect than we have usually seen them at the same time of year. Mr. Turner, who was first, exhibited the ripest, and these were fine bunches with large berries. Those from Mr. Chambers, gardener to H. Fowler, Esq., Woodford, were also very good. Mr. Deasley, gardener to Mr. Wood, Twyford Abbey, Ayles, was third.

On White Grapes, with a Muscat flavour, Muscat Troveron from Mr. Standish, was awarded the first prize, and *Chasselas Musque*, from Mr. Fowler, the second. Mr. Ruffitt, gardener to Viscount Palmerston, was third.

For three bunches of any other White kind the first prize was awarded to Mr. Osborne, Finchley, for Buckind Sweetwater, very fine, and even in size of berry; the second to Mr. Fowler, gardener to the Earl of Stair, for fair bunches of Golden Hamburgh with good-sized berries, but apparently not sufficiently ripe, and the third to Mr. Bannerman for small bunches of the same kind, but well ripened.

The best single bunch of Black Grapes was Black Hamburgh, well shouldered and finely coloured, from Mr. Allport, and the second best the same kind, from Mr. Osborne, large in bunch and berry, but not quite perfect in colour. In the corresponding class for White Grapes, Mr. Turner was first with splendid *Muscats* just acquiring a yellow tinge, Buckind Sweetwater, from Mr. Osborne, very fine but scarcely quite ripe, was awarded the second prize.

OF VINES in pots, Messrs. Lane exhibited four splendid specimens in 20-inch pots, and loaded with large bunches. The kind were Buckind Sweetwater, Alicante, Black Hamburgh, and Foster's White Seedling. These were awarded a first prize, and a like award was made to Mr. Record, gardener to Lieut.-Col. Lloyd, Hawkhurst.

MUSCATS were not numerous. The best of the Green-fleshed was *Meredith's Hybrid Calamagne*, from Mr. Smith, gardener to H. Littledale, Esq., Epsom Hill. Mr. Bennett, gardener to G. S. Poljanec, Esq., Osherton Hall, was second; and Mr. Whiting, gardener to Mrs. H. P. The Dredene, third. In the Scarlet-flesh class, Mr. Lane, gardener to J. Miles, Esq., was first, with *Scarlet Gem*; Mr. Balseg, gardener to J. Gott, Esq., Arnsley, second; and Messrs. Gadd, third.

PEACHES AND NECTARINES.—But few of either were exhibited, but what there were was good in quality. Mr. Gardner, gardener to Sir George Phillips, St. James's Palace, was first, with what appeared to be Royal George; Mr. Turner second, with *Cross Mignonne*, well coloured, and first in Net vines with Hunt's Tawny, Mr. Tegg, gardener to the Duke of Newcastle, being second. In the class for three dishes of the same fruit, Mr. Evans, gardener to C. N. New Regent, Esq., M.P., was first, with Red Roman, Elrage, and *Vilette* *Native*.

FIGS.—Only a few dishes were shown. Very good Brown Turkey, from Mr. Peaburn, Slough, was first; the same kind from Mr. Tegg and Mr. Snow, West Park, second and third. Some fine fruit of the Castle Kennedy, together with branches of it bearing freely, were shown among miscellaneous subjects.

STRAWBERRIES.—Several fair dishes were exhibited. There was only one exhibitor in the class for six kinds—Mr. Widdowson, gardener to J. Barnes, Esq., Rickman, worth, who had a first prize for Oscar, Sir Harry, Sir C. Napier, President, Empress Eugenie, and River's Seedling. For three kinds, Mr. O'Brien, gardener to R. P. King, Esq., Brist. was first with very good fruit of Oscar, Dne de Malakoff, and *Teddlap's Victoria*. In single dishes, Mr. Brevet, gardener to Mrs. Cabitt, Dobbies, was first, with Alice M. side; Mr. O'Brien, second, with *Teddlap's Victoria*, and Mr. Irvine, gardener to the Duke of Hamilton, Wickham, third with *Marguerite*. Very good Strawberries in pots, from Mr. Fairbank, with the fruit equally ripened, received a first prize.

CUMBUSS.—But few were shown. The first prize went to Empress Eugenie, from Mr. Ruffitt; the second to Black Tartarian, from Mr. Allen, gardener to Capt. Glegg; and the third to Mr. Carr or Knight's Early Black, and the same exhibitor had a similar award for Elbow. A pot plant of Frogmore Forcing Cherry, a new kind allied to Vermer's Early Heart, and in excellent bearing, was exhibited by Mr. Turner, of Slough, and was awarded a first-class certificate.

RASPBERRIES.—Only two dishes, red and yellow, were shown. These came from Mr. Allen, gardener to E. J. Hopwood, Esq., Manchester, and were awarded second prizes.

MISCELLANEOUS.—In a class specially appropriated to Bananas a fine cluster of *Musa Cavendishii* from Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet was first; and a smaller one from Mr. Batger, gardener to J. Gott, Esq., Armley, second. From the gardens of O. F. Meyrick, Esq., there was also fruit of *Philodendron pertusum*, and from Mr. Taylor, gardener to J. Yates, Esq., Highgate, the curious fruit of *Bion edule*. Mr. Cameron, gardener to the Duke of Richmond, Goodwood, exhibited four fine Queen Pines; and Mr. Evans, gardener to C. N. Newdegate, Esq., a box of well ripened *Violette Hative* and *Elrue Nectarines*. Mr. Hazlewood, Hoddesdon, contributed excellent examples of Oranges and Citrons; and Mr. Ford, gardener to W. Hulburd, Esq., Horsbarnham, a collection of Apples and Pears in excellent condition, comprising of Apples Pearson's Plate, Norfolk Beating, New Rock Pippin, Dutch Mignonette (fine), Alfriston, Holland Pippin, Royal Russet, Manington's Pearmain, French Crab, Royal Pearmain; and of Pears, Knight's Monarch, Easter Beurre, and March Bergamot; also Citrons and Oranges of home growth. Mr. Snow, West Park, had very fine Court-Pendul-Plat, Scarlet Nonpareil, Beauty of Kent, Reinette du Canada, Sturmer Pippin, Boston Russet, and Old Green Nonpareil Apples, and The Warden Pear. In a collection from Mr. Barnett, gardener to the Rev. W. Garnett, were Beurre de Rance, very fine, clear-skinned and sound, and *Ne plus Meuris*. Well-kept Apples also came from Mr. Lumsden, gardener to Lady Mary Hamilton, and Mr. Divers, of Staplehurst. Vanilla pods were shown by Mr. Bennett, gardener to G. Foljamba, Esq., Osberton; Oréhard-houze trees in fruit of Oranges, Figs, Peaches, and Nectarines by Messrs. Lane and Mr. T. Morten, Amersham. The only examples of training exhibited came from Messrs. Jamin and Durand, Paris, and represented various forms of palmate and pyramidal training as applied to the Apple, Pear, Peach, and Apricot.

In concluding our remarks on the above portions of the Exhibition, a word of praise is due to Mr. Thomas Moore, the Exhibition Secretary, for the excellence of the arrangements in his department, in carrying out which he was ably seconded by Mr. R. Dean, the Assistant-Secretary, and in the entry department by Mr. Flood.

VEGETABLES.

At this grand Exhibition the old rule in gentlemen's gardens of making vegetables the first consideration, fruit the second, and ornamental plants the third, was thoroughly reversed; for though fruit and vegetables were more than respectable, neither in quantity, nor in quality, could they compare with the magnificence of the ornamental department.

In Class 201, Forced vegetables of six kinds, without salading, there were five entries; the first prize being taken by Mr. Carr, gardener to the Rev. J. W. Micklethwait, Taverham Hall, Norwich, and consisted of Mushrooms, rather old; early Turnips, small; Carrots, very good; Ash-leaved Kidney Potatoes; Dwarf Kidney Beans, nice and crisp; and Tom Thumb Pea in good condition. Second prize was taken by Mr. R. Budd, gardener to the Earl of Darnley, Cobham Hall, Gravesend, and consisted of Tomatoes, ripe; Carrots, small; a dish of small Mushrooms, good Sea-kale, young crisp Dwarf Kidney Beans, and a pretty dish of Kidney Potatoes named *Mona's Pride*.

In Class 202, Vegetables not forced, six kinds, first prize to Mr. Bailey, gardener to P. T. Drake, Esq., Sharnbeles, Amersham, and consisted of Carrots, fine Broccoli, good Leeks, good Cabbage, Potatoes, and a good bundle of Asparagus. Second prize to Mr. Whiting, gardener to Mrs. Hope, of the Deepdene, Dorking, for fine round Potatoes, Asparagus, Broccoli, Cabbage, Spinach, and Onions. Third prize to Mr. Budd, gardener to the Earl of Darnley, Cobham Hall, for good Onions, good old Carrots, Broccoli, Cabbage, Leeks, and Asparagus.

In Class 203, Salading, ten sorts, first to Mr. Mason, Market Gardener, Lower Road, Deptford, for Mustard and Cress, two kinds of Lettuces, two of Radishes, Onions, Endive, Cucumber and Celery. Second, Mr. Budd, gardener to the Earl of Darnley, for a nice collection. Third, Mr. Lumsden, gardener to Lady M. C. N. Hamilton, Bloxholm Hall, Slough. The Cabbage Lettuces in this collection were extra good.

In Class 204, fifty heads Asparagus, first to George Tippett Hassell, Esq., Barton Hill, Bristol. Second, Mr. Snow, gardener to the Countess Cowper, West Park, Silsoe, Beds. Both good.

In Class 205, twelve largest heads of Asparagus, first, George Tippett Hassell, Esq. Second, J. Cocks, Esq., West Moulsey Lodge (J. Pendold, gardener).

In Class 206, Mushrooms, one punnet, first, Mr. Budd, gardener to the Earl of Darnley, for a nice sample. Second to E. J. G. Hopwood, Esq., Hopwood Hall, Manchester (W. Allen, gardener). Other good dishes of larger Mushrooms were shown.

In Class 207, Potatoes forced. Kidney, first to Mr. H. W. Cordle, gardener to the Earl Fitzwilliam, Coolatten Park, Carnew, Wicklow, for a beautiful dish of the Prince of Wales Kidney. Second to Mr. Lumsden, gardener to Lady M. C. N. Hamilton. Third, Mr. Whiting, of the Deepdene.

In Class 208, Potatoes forced, twenty-four of any round kind, first, very nice dish from Mr. Thomas Westbrook, Abingdon, Berks. Second, Mr. Snow, of West Park.

In Class 209, Kidney Beans forced, fifty pods. These in general were fine pods in nice young condition. First to J. S. Oates, Esq., Floral Villa, Hamwell. Second, E. Oates, Esq., Bydorp House, Hamwell (gardener, Richard Marchant). Third, J. Gott, Esq., Armley House, Leeds (E. Batger, gardener).

In Class 210, Peas, half a peck, only one dish, a good one, exhibited

by Mr. Turner, of Slough. In these days of early vegetables, we were surprised that Peas were not more numerous.

In Class 211, Early Carrots, bunch of twenty-four, first, Mr. Snow, of West Park. Second, Mr. Whiting, of the Deepdene. Most of the Carrots that were not prizetakers were rather young.

In Class 212, Early Turnips, bunch of twelve. Did not perceive any shown separately; of course they could only have been slightly forced ones.

In Class 213, Cucumbers, one brace, first, Mr. John Rabbitt, gardener to the Lord St. John, Melchbourne Park, Higham Ferrars. The kind, *Invincible*. Second, H. Littledale, Esq., Liscard Hall, Cheshire (G. Smith, gardener).

In Class 214, The handsomest Cucumber, first, Mr. Rabbitt, gardener to the Lord St. John, of Melchbourne Park, for *Invincible*. Again a good-looking show of Cucumbers. Second to Mr. H. Carr, Jeffries' Arboretum Nurseries, Ipswich (Jeffrey's Gem). Third, Mr. John Jennings, Shipston-on-Stour.

In Class 215, Cucumber, the longest, first, Mr. John House, East Gate Nursery, Peterborough. Second, Mr. H. Carr, Jeffries' Arboretum Nurseries, Ipswich. Third, Mr. John Jennings, Shipston-on-Stour.

Except for securing size and length, the most of the many Cucumbers exhibited were too old for use. Where fine-sized fruit formed a feature the end had blown on a small neat brace of about a foot or 14 inches in length, and great was the commotion even among the outsiders, as to the reason why these little fresh things should have a prize. If Cucumbers had been shown on the principle of fittest for the table, we confess that in our opinion that small neat brace would have run more than hard those three times in bulk and weight.

In Class 216, Rhubarb, heaviest twelve stalks, first, Mr. Whiting, gardener at the Deepdene. Second, Mr. John Cattell, Nurseryman, Westerham. Third, R. Barclay, Esq., West Hill, Highgate (W. Young, gardener). The kinds shown were chiefly Myatt's Victoria.

In Class 217, Cabbage, three heads, first, Mr. Snow, gardener at West Park, for nice firm compact heads. Second, W. Earley, gardener to P. Pryor, Esq., Digswell, Welwyn. These Cabbages were very good, but most of the Cabbages were too young, with flabby leaves, instead of compact hearts getting firm.

In Class 218, Cauliflowers, three heads, first to John Cattell, Nurseryman, Westerham, Kent. Second, Mr. Snow, of West Park. These collections had firm, white, compact heads. There were few Cauliflowers on the tables.

In Class 219, Broccoli, three heads, first, Mr. Cattell, for Cattell's Eclipse, very compact firm heads. Second, Mr. Whiting, of the Deepdene, with Cattell's Champion. Third, Mr. T. Record, gardener to Lieut. Col. Lloyd, Hawkhurst, Kent, with larger but more open heads. Besides these, and others not placed, we noticed three fine compact heads of Garaway's late White, from Messrs. Garaway and Co., of Durdham Down Nursery, Bristol. These seemed us if they would bridge us over nicely between late Broccoli and early Cauliflower.

In Class 220, Newly introduced vegetables, we did not observe the prizes given, but there were good specimens of *Dioscorea batatas* from Mr. Crickshank, gardener to W. Jones Loyd, Esq., Langleybury, Watford; and from the Messrs. Ivery, of Dorking, though these could scarcely be considered new vegetables. Then a large space was filled with the new Radish, *Raphanus candatus*, sent by Mr. Bull, of Chelsea, which, even in small pots, produced freely its whip-like pods. We did not taste the pods, and therefore can say nothing of its qualities; but its distinct and singular appearance, and free growth, will, we have no doubt, make it pretty generally diffused next season.*

IMPLEMENTS, &c.

There was next to an impossibility of coming to a decision on the merits of many implements, because there was no chance of trying them in practice, and the absence of cards left the Jurors in doubt whether the objects were intended for competition or not. There did not seem to be anything new in the great numbers of small mowing machines, and the best could only be decided on by trial, and price, &c., taken into consideration. This was partly broken through when a first certificate was awarded Mr. Read for syringes, pumps, and engines, owing to their superior workmanship; and an award was made to Messrs. Warner & Sons for a similar collection, all priced. A horse-shoe covered with wood, to be used for rolling and mowing lawns, was shown by Mr. Henderson, gardener to Sir G. H. Beaumont, Bart., Cole Orton Hall, Ashly-de-la-Zouch, which, if it do not crack, become slippery, or turn up the edges of the turf, will have the advantage of not keeping the horse's feet too hot, which boots are apt to do. This injuring of the feet of the horse from the use of boots is a great thing against their employment, unless for short periods. Models of Paxton's, Cranston's, and Ingram's Strawberry-houses, and Will's patent folding-ground viney were passed for reasons stated above, and it is not now containing anything new. Tubular saddle boilers were exhibited by Messrs. Cumming and Edmonds, Stamford Bridge, Brompton, S.W., in which the saddle consists of circular tubes. In some cases the bottom of the furnace is formed of tubes, and in the other of bars in the usual way, and we rather like that best, just as other men of even

* This is not a new vegetable. Nearly fifty years ago, Mr. Lambert, President of the Lincæan Society, found it growing in a private garden in Wiltshire.

greater experience prefer tubes. These small boilers, we have no doubt, will answer well for small places, though it is doubtful whether the tubes of the saddle will be better than the common saddleback. Another boiler was exhibited with furnace complete, and a lid fitting the inclined plane to the bars, and at night a galvanised tube to be fitted to this opening filled with fuel to descend gradually to the bars. We wonder how long such a tube would stand when used by a common labourer. For a careful amateur, who does not like looking to his fire often, the supply-tube would be useful in a cold night. A prize was given to Mr. Gray for his oval double tubular boiler, though there is not much of the oval in it; but those who have worked it say that it is a powerful boiler when much work is to be done with it. In wheelbarrows there was nothing to merit special attention, though improvements are much needed. For sunshades for garden seats a certificate was awarded to Mr. Scowan, patent canopy maker, Allen Road, Stoke Newington, each supported by a stout rod of brass, and which can be moved according to the direction of the wind. Prices not given.

In Class 231 (G), a prize was awarded to Mr. W. Earley, gardener to F. Fryor, Esq., Digswell, Welwyn, Herts., for a guard for protecting young trees from animals in parks, &c. It is made of stout iron, with feet to go in the ground, with wire for 2 feet in height to keep out small intruders; is neat and artistic in appearance, and is to cost only 30s. It would be well if exhibitors would state the price of the things exhibited. This guard is really good. It is made in two semicircular pieces, and then joined when placed round the tree with screws and nuts.

In Class 231 (C), Mr. Charles Lee exhibited a strong two-wheeled transplanting machine, and which can be built for £20. In principle it would act much the same as the old timber-gig. As combining the novel and the adaptable, to circumstances, such as passing through narrow gates and on narrow walks, the prize was given to a machine constructed by Mr. J. McIndoe, gardener to Coles Child, Esq., Bromley, Kent. Speaking from memory we cannot well describe its size, &c.; but the two wheels at back are of iron, occupying about a yard in width altogether, have a strong pole attached by means of bands of iron, which rise far above the level of the wheels. To the sides of the pole are attached strong canvas, cordage, or chains, for passing under the ball of the tree, and then that is raised by leverage in the usual way. Between these two iron wheels, and on the same axis, is placed a narrow wheel, notched for a ratchet wheel, and the turning of this with handle enables the operator to place the machine backwards and forwards with very little application of physical strength. To make this all the more easy when the tree is lifted and the pole brought to the ground in front, a small wheel on each side these causes the whole to be moved when empty or loaded with great ease.

In Class 231 (D), for the best mode of ventilating plant-structures, the prize was awarded to Messrs. Sanders, Frewer & Co., Bury St. Edmunds, for one of Beard's patent metallic non-conducting glass houses, the main features of which have been previously described in the Journal. A small sash all along the apex is made to open by leverage, and the same takes place in front; and a distinguishing feature is, that the opening is made close to the surface of the ground outside. The mode of opening and shutting all these ventilators at once is very simple.

The models sent by Mr. Newton, landscape architect, did not seem simple enough to be appreciated by the Jurors, more especially as there was no one to explain the objects.

DESIGNS FOR LAYING OUT A PRIVATE GARDEN on the scale of 40 feet to the inch, the space twenty acres, &c. (Class 235).—The prize was awarded to J. W. Chapman, Hermitage Road, Richmond, Surrey. The object seems to have been to cluster the offices, &c., on one side of the mansion, and the flower garden on the other side and in front close to the house. Garden front, open lawn with but few trees, sides skirted with masses of shrubs in the picturesque style; a lake in front in the distance. Entrance through a lawn open, but sheltered, and the sides, &c., well grouped. A good design.

In laying out an oblong of five acres on a scale of 10 feet to the inch, the prize was awarded to Mr. Thomas J. Caporn, King's Road Nursery, Newark; and though there was more of the artistic shown, and there was more massing at the sides of the lawn and walks through the wood and shrubberies, there was the same principle of an open lawn on the garden front developed and maintained. Such designs will help to show the importance of ease and breadth of view close to a mansion. Dotted the lawn with flower-beds would have spoiled the effect in either place. It would improve many places if the lawn were enlarged at the expense of flower-beds, and there was more green and less colour, however bright in summer, and less of dull earth in winter.

GARDEN ORNAMENTS (Class 232).—There were some pretty large vases formed of ribs of iron and then covered with the turf to keep in the soil, shown by Messrs. Hunt & Pickering, of Leicester; and Italian baskets shown by Mr. Bull, of Chelsea. A certificate was awarded to vases, fountains, &c., of artificial stone, sent by Messrs. Rosher, Queen's Road West, Chelsea. Also, to Mr. Thomas, 6, Newcastle Place, and 133, Edgeware Road, Paddington, for wire arches, seats, temples, and trainers; but chiefly for the great variety and artistic beauty of many suspended wire baskets, &c.; also, for a nice collection of rustic work in wood, of seats, baskets, and tables, of the proprietor of which no name was attached. Also, for some nice garden chairs with wooden-spurred bottoms, but the back done very artistically and nicely with metal bronzed. There was a great variety of this style of chairs,

mostly of wood with the exception of the framework, but these chairs with metal backs were taken out of the class of garden utilities into that of garden ornaments, and as people do not lean much again to such chairs, the wooden bottoms made them almost equal in point of comfort for the sitter, &c., to those formed all of wood. I know that it is common to see iron chairs and wire chairs stuck about in all quarters, but few things could be more uncomfortable either in cold or wet weather, owing to the absorption and radiation of heat. A great improvement was effected when these chairs were made with wooden bottoms. There was no name attached to this exhibition, but for elegant places these chairs are a march in the right direction. No prices were given, but the common Leicester chair to hold three or more persons may be had according to the style of the painting, from 15s. to 25s.

A prize was also awarded for two nice designs of rockwork or ruins, suitable for Ferns, sent by Mr. E. A. Puig, Grove Terrace, Grove Road, St. John's Wood.

Of Orange tree tubs, there was a great variety, and among others was one of stained or varnished wood, which would look well in an ornamental conservatory attached to a suburban rustic mansion; but if we proceed as we are now doing, the time will not be far distant when the floor of conservatories close to a palatial mansion will be covered with marble, and the tubs, or rather the artistic vases, will be made of the finest china, with rougher lining inside to keep them from injury. Once we saw a marbled-floored conservatory, and some baskets of plants on it, the baskets made of common wire, green painted! The finest and a different marble would have been more appropriate material for pots to stand on the marble of such a floor.

BOTANICAL CONGRESS.

THE first meeting of the Botanical Congress was held in the Raphael Room of the South Kensington Museum, May 23, at 11 A.M., Professor De Candolle in the chair.

A very large meeting, including almost all the British and foreign botanists and horticulturists present in London, assembled to hear the President's address, and a large number of ladies graced the meeting with their presence. Before proceeding to the business of the meeting, Professor DE CANDOLLE spoke as follows:—

"Before I commence my address in French, allow me to say a few words in English—first, as a mark of respect to this great country, and next, in explanation of my views for the conduct of present and future meetings of this kind. We have to choose between two alternatives: either that every member should speak in his own language, or in that of the country where the congress meets. This last method would destroy the equality between members which is desirable in every public assembly. Not a few would be reduced to silence, or at least prevented from taking part in the discussion, and several distinguished men would therefore avoid international congresses. The other plan of letting every one speak in his own language appears to be much more convenient. For these reasons I shall address you in French, and in doing so I establish in fact the right of every Englishman to speak in English at Paris or at Berlin, at Florence or at Vienna, under similar circumstances."

The SECRETARY then announced that the following gentlemen had been elected Vice-Presidents of the Congress:—Professor Leconte, Clermont Ferrand; Dr. Weddell, Poitiers; Professor Kickx, Ghent; Professor Morren, Liège; Professor Caspary, Königsberg; Professor Reichenbach, Hamburg; Professor Karl Koch, Berlin; Dr. Schulz Bipontinus, Deidesheim; M. Hermann Wendland, Hanover; Professor Meisner, Basle; Signor Triana, New Grenada.

The following works were laid on the table:—

Dr. Hasskarl: a manuscript *Clavis to Rheedee's "Hortus Malabaricus;"* some papers from Professor Gasparini; an illustrated work on the species of Cotton, by Professor Parlatore, &c.; some exceedingly beautiful water-colour drawings, with analyses of flowers, by Mr. Julius Phatzmann, of Leipzig; also several beautiful drawings of British plants, by Mr. W. G. Smith.

Professor DE CANDOLLE then read his inaugural address, on the conclusion of which a vote of thanks was proposed by Sir C. Wentworth Dilke, M.P., and seconded by Sir Rodrick Marchison, who took the opportunity to allude to the philosophic views of M. De Candolle, and to the masterly way in which he had handled his subject.

Mr. BENNETT, on the part of the botanists of Britain, also tendered his thanks to the eminent Chairman for the honour he had conferred on them by presiding on the occasion, and specially for the preparation of so admirable an address.

Professor DE CANDOLLE briefly replied.

Dr. SCHULZ BIPONTINUS, a Vice-President of the Imperial Leopoldine Academy, offered the congratulations of that learned and ancient body to the President and members of the Botanical Congress.

Dr. MOORE then exhibited specimens of *Megacarpaa polyandra*, a Crucifer with fifteen stamens, which excited great interest among the botanists present.

Mr. RIVERS then made some remarks on seedling Peaches and Nectarines.

Professor CASPARY then spoke on the movement of the branches of woody plants caused by low degrees of temperature.

Mr. HOWARD'S paper on the *Cinchona* was then read; and in the discussion that followed, Dr. Weddell said that he approved of the spelling of the name of the genus as adopted by Linnæus. This

paper was illustrated by numerous specimens of Cinchona barks, of dried specimens of the plants, grown in India and collected by Mr. Markham, &c.

Professor Koch then made some remarks on the nomenclature of plants, &c., and the meeting adjourned.

The second meeting of the Botanical Congress was held on Thursday, in the Sheepshanks Gallery, which was well filled throughout the whole proceedings.

The first paper read was that of Dr. MOORE, Glasnevin, on the climate, flora, and crops of Ireland; the next that of Professor Lecoq.

Mr. HOWLETT exhibited a model of an apparatus which should combine shading with night-covering of plant-houses, by means of one contrivance fitted to the roof. It was considered that for most purposes this contrivance would exclude the light too much.

Mr. ANDERSON'S paper on Orchid culture excited an animated discussion, in which Professor Daubeny, Professor Reichenbach, Mr. Bateman, M. Alfred de Morney, and Mr. Howlett took part, all advocating the justice of Mr. Anderson's views.

Mr. KRILLAGE next addressed the meeting in German, on the nomenclature of plants.

Dr. DICKSON, Edinburgh, read some remarks on the leaves of Sciadopitys and Phyllocladus, which he considers in the light of leaf-like branches rather than as true leaves, a view in which Professor Caquary did not fully coincide.

Professor DE CANDOLLE exhibited a measure, on a long strip of paper, of the trunk of one of the gigantic Sequoias of California. The enormous dimensions were well exemplified by the length of the strip, which extended well high from one side to the other of the room. The rate of growth was carefully noted by counting the annular rings.

Professor REICHENBACH addressed the meeting in English on certain peculiarities of Orchid structure. In the course of the discussion that ensued on this subject, Mr. Bateman said that he had seen a branched spike of *Oblongosium grande*, and Dr. Masters said he had also met with a similar case in *Ophrys aranifera*.

Professor MORREN, of Liege, treated at some length on the influence of coal gas on plants, and detailed his experiments on this point.

Mr. W. G. SMITH then stated his views as to the corona of Narcissus.

Several other communications were read, including one from M. Andre, Paris, and the President declared the Congress at an end; on which Mr. Bennett proposed, Dr. Daubeny seconded, and Dr. Schinz Bipontium supported, a cordial vote of thanks to the President.

THE CONVERSAZIONE.

THE Conversazione on the evening of the 23rd was held in the Raphael Room at the South Kensington Museum. There was a brilliant attendance.

M. DE CANDOLLE'S ADDRESS TO THE CONGRESS.

In order to derive the full advantage from a meeting of so many lovers of science, horticulturists and botanists, brought together from all parts of Europe, it is necessary that the common object for which they have met should be perfectly understood.

It devolves on me, who am called upon to preside in honour of which I feel myself unworthy, to point out the bond which unites us, and of which, perhaps, you have at present but a vague, and, so to speak, an intuitive perception.

In my opinion, we are not here merely as amateurs to satisfy our curiosity. The proof of which is, we are here assembled to listen to discussions, instead of wandering about the fairy-like garden of the Exhibition. Evidently we seek something more than a mere show, and that something is, in my opinion, instruction. It is not sufficient for horticulturists merely to see—they must also study and reflect. Neither is it sufficient for botanists to observe details minutely; they must also see the plants on a large scale, and in grouped masses. The connection of Practice with Theory, and of Art with Science, is acknowledged to be indispensable; and in accordance with this prevalent opinion we here affirm, by our presence in this room, the necessary union of Botany and Horticulture. The aim of my brief observations will be to call to mind how they aid each other, and to show how much more they might do. If I am not mistaken, it will follow from facts to which I shall allude, that our united efforts, scientific or practical, modest though they appear, contribute to increase the well-being of man, in all conditions and in all countries.

FIRSTLY—THE ADVANTAGES OF HORTICULTURE TO BOTANY.

Let us first mention the services that horticulture renders, or may render, to botany. Without being myself a horticulturist, I affirm or recognise them willingly, the advancement of Science rendering it necessary to have recourse to all its collateral branches.

We no longer live in those times of illusion when botanists merely occupied themselves with European plants, or with a few from the East, and, from a spirit of caution rather than from ignorance, pictured to themselves all distant countries as possessing much the same general vegetation, with a few uncommon or exceptional species. A century of discovery has made known the extreme variety in the Floras, the restricted limits of many species, and the complicated entanglement of their geographical distribution. To see all the different forms of vegetation of the world, one would realise in a degree the

history of the Wandering Jew; besides, with this constant travelling, where would be the opportunities for that reflection or study which create true science?

The traveller is too much exhausted in warm countries, too distracted in those temperate regions favourable to active life, and his faculties are too much benumbed in the colder regions, to enable him to devote himself to minute researches with the lens or the microscope, or even to sketch or properly describe that which he has gathered. He sees, in passing, a crowd of things, but he can scarcely ever stop to enter into details, especially of those that come in rapid succession. Rarely can he see the fruit and flower of a species at the same time, and it is quite impossible for him to study their complete development during the whole year. The notes taken by the most intelligent naturalist are so affected by these fatal circumstances, that it is seldom they add anything to that which a dried specimen can teach the sedentary botanist.

It is horticulture, then, which brings before us a multitude of exotic plants in a condition best adapted for study. Thanks to the variety of species it accumulates and successfully cultivates, the botanist can investigate the most difficult questions, and pursue his researches in families whose genera are not indigenous in Europe. In the herbarium, more minute observations can be made than is generally supposed; nevertheless, for certain researches, it is absolutely necessary to have the living plant, particularly for those relating to relative disposition, the origin and development of the several organs, as well as for studying the curious phenomena of fertilisation, the movements and direction of the stem, leaves, and parts of the flowers. Horticulture has done much to advance the progress of physiological botany, but it still has much to do. The most remarkable experiments of physiologists—viz., those of Hales, Duhamel, Knight—have been made in gardens. Also, the long series of experiments of the younger Gaertner, and, more recently, of M. Naudin, on hybridisation, which relate to the cardinal subject of the species. As much may be said of the numerous trials which are made, in horticultural establishments, to obtain new races or varieties. These have a great scientific importance, and it is undoubtedly the horticulturists who are the teachers of botanists on these subjects.

It appears to me, however, that gardens can be made still more useful in carrying out physiological researches. For instance: there is much yet to be learnt on the mode of action of heat, light, and electricity upon vegetation. I pointed out many of these deficiencies in 1855, in my "Geographic Botanique Raisonnée." Ten years later, Mr. Julius Sachs, in his recently published and valuable work on physiological botany, points out much the same deficiencies, notwithstanding that some progress has been made in these matters. The evil consists in this, that when it is desired to observe the action of temperature, either fixed or varied, mean or extreme, or the effect of light, it is exceedingly difficult, and sometimes impossible, when observations are made in the usual manner, to limitate the effects of the constant variations of heat and light. In the laboratory it is possible to operate under more exactly defined conditions, but they are rarely sufficiently persistent; and the observer is led into error by growing plants in too contracted a space, either in tubes or bell-glasses. This last objection is apparent when it is wished to ascertain the influence of the gases diffused in the atmosphere around plants, or that of the plants themselves upon the atmosphere.

These plants under a receiver, they are no longer in a natural condition; leave them in the open air, and the winds and currents, produced at each moment of the day by the temperature, disperse the gaseous bodies in the atmosphere. Every one is aware of the numerous discussions concerning the more or less pernicious influence of the gases given off from certain manufactories. The run now of a manufacturer, now of a horticulturist, may result from the declaration of an expert; hence, it is incumbent on scientific men not to pronounce on these delicate questions without substantial proof.

With a view to these researches, of which I merely point out the general nature, but which are immensely varied in details, I lately put this question:—"Could not experimental greenhouses be built, in which the temperature might be regulated for a prolonged time, and be either fixed, constant, or variable, according to the wish of the observer?" My question passed unnoticed in a voluminous work where, in truth, it was but an necessary. I renew it now in the presence of an assembly admirably qualified to solve it. I should like, were it possible, to have a greenhouse placed in some large horticultural establishment or botanic garden, under the direction of some ingenious and accurate physiologist, and adapted to experiments on vegetable physiology; and this is, within a little, my idea of such a construction:

The building should be sheltered from all external variations of temperature; to effect which, I imagine it should be in a great measure below the level of the ground. I should have it built of thick brickwork, in the form of a vault. The upper convexity, which would rise above the ground, should have two openings—one exposed to the south, the other to the north—in order to receive the direct rays of the sun or diffused light. These apertures should each be closed by two very transparent glass windows, hermetically fixed. Besides which, there should be, on the outside, means of

* Pages 46, 49, 57, and 1346.

† "Handbuch der experimental-physiologie der pflanzen," 1 vol. in 8vo. Leipzig, 1865.

‡ "Geographic Botanique," 1855, pages 49 and 1346.

excluding the light, in order to obtain complete darkness, and to diminish the influence of the variations of temperature when light was not required. By sinking it in the ground, by the thickness of its walls, and by the covering of its exterior surfaces with straw, mats, &c., the same fixed degree of temperature could be obtained as in a cellar. The vaulted building should have an underground communication with a chamber containing the heating and the electrical apparatus. The entrance into the experimental hot-house should be through a passage closed by a series of successive doors. The temperature should be regulated by metallic conductors, heated or cooled at a distance. Engineers have already devised means by which the temperature of a room, acting on a valve, regulates the entry or exit of a certain amount of air, so that the heat regulates itself.* Use could be made of such an apparatus when necessary.

Obviously, with a hot-house thus constructed, the growth of plants could be followed from their germination to the ripening of their seeds, under the influence of a temperature and an amount of light perfectly definite in intensity. It could then be ascertained how heat acts during the successive phases from sowing to germination, from germination to flowering, and from this on to the ripening of the seed. For different species various curves could be constructed to express the action of heat on each function, and of which there are already some in illustration of the most simple phenomena, such as germination,† the growth of stems, and the course of the sap in the interior of certain cells.‡ We should be able to fix a great number of those minima and maxima of temperature which limit physiological phenomena. Indeed, a question more complicated might be investigated, towards the solution of which science has already made some advances—namely, that of the action of variable temperature; and it might be seen, if, as appears to be the case, these temperatures are sometimes beneficial, at other times injurious, according to the species, the function investigated, and the range of temperature. The action of light on vegetation has given rise to the most ingenious experiments. Unfortunately, these experiments have sometimes ended in contradictory and uncertain results. The best ascertained facts are, the importance of sunlight for the development of the green colouring matter, the decomposition of carbonic acid gas by the foliage, and certain phenomena relating to the direction or position of stems and leaves. There remains much yet to learn upon the effect of diffused light, the combination of time and light, and the relative importance of light and heat. Does a prolonged light of several days or weeks, such as occurs in the Polar Regions, produce in exhalation of oxygen, and in the fixing of green matter, as much effect as the light distributed from twelve to twelve hours, as at the Equator? No one knows. In this case, as for temperature, curves should be constructed, showing the increasing or diminishing action of light on the performance of each function; and as the electric light resembles that of the sun, we could in our experimental hot-house submit vegetation to a continued light.§

A building such as I propose would allow of light being passed through coloured glasses or coloured solutions, and so prove the effect of the different visible or invisible rays which enter into the composition of sunlight. For the sake of exactness nothing is superior to the decomposition of the luminous rays by a prism, and the fixing the rays by means of a heliostat. Nevertheless, a judicious selection of colouring matters, and a logical method of performing our experiments, will lead to good results. I will give as proof, that the recent most careful experiments concerning the action of various rays upon the production of oxygen by leaves, and upon the production of the green colouring matter, have only confirmed the discoveries made in 1836, without either prism or heliostat, by Professor Daubeny, from which it appears that the most luminous rays have the most power, next to them the hottest rays, and lastly those called chemical.

Dr. Gardner in 1843. Mr. Draper immediately after, and Dr. C. M. Guillemin in 1857,¶ corroborated by means of the prism and

* See the electric apparatus of M. Carbonnier, exhibited at Chiswick in 1857, figured in the "Flore des Serres et Jardins," vol. xii. Miscell. p. 184.
 † Germination under different degrees of constant heat, by Alph. de Candolle, in the "Bibliothèque Universelle de Genève" (Archives des Sciences, November, 1865).

‡ If the curves have not been constructed, the data for their construction are, at least, dispersed throughout our books. I will cite, for instance, the growth of a scape of *Dasyllirion*, as observed by M. Ed. Morren ("Belgique Horticole," 1865, p. 322). The figures there given are not favourable to the accepted notion, that the growth of tissues is more active by night than by day.

§ The apparatus which produces the most persistent and vivid light is the magneto-electric machine, based on the development of induction by magnetism, as discovered by the illustrious Faraday. The galvanic pile is replaced by a steam-engine of low power, which sets in motion a wheel furnished with magnets ("Bibl. Univ. de Genève, Archives Scientif., 1861, v. 10, p. 169."). The working of this machine is inexpensive; but unfortunately, the magnets are very costly. This system has already been applied to two light-houses,—that at the South Foreland, and to that of the "Société l'Alliance," at Havre—in consequence of the experiments of MM. E. Becquerel and Treca.

¶ Daubeny, "Philos. Trans.," 1836, part 1.

the heliostat the discovery of Dr. Daubeny, which negated the opinions prevalent since the time of Senebier and Tessier, and which were the result of erroneous* experiments. It was difficult to believe that the most refrangible rays—violet for instance, which acts the most on metallic bodies—as in photometrical operations, should be precisely those which have least effect in decomposing the carbonic acid gas in plants, and have the least effect over the green matter in leaves. Notwithstanding the confirmation of all the experiments made by Dr. Daubeny, when repeated by numerous physicists and by more accurate methods, the old opinions, appearing more probable, still influenced many minds,† till Mr. Julius Sachs, in a series of very important experiments again affirmed the truth.‡ It is really the yellow and orange rays that have the most power, and the blue and violet rays the least, in the phenomena of vegetable chemistry; contrary to that which occurs in mineral chemistry, at least in the case of chloride of silver. The least refrangible rays, such as orange and yellow, have also the twofold and contrary property, such as pertains also to white light, and which produces the green colouring matter of leaves or bleaches them, according to its intensity. It is these, also, which change the colouring matter of flowers when it has been dissolved in water or alcohol.‡ Those rays called chemical, such as violet, and the invisible rays beyond violet, according to recent experiments, confirmatory of those of ancient authors—those of Sebastian Pogglioli, in 1817, and of C. M. Guillemin—have but one single well-ascertained effect, that of favouring the bending of the stem towards the quarter from which they come more decidedly than do other rays; yet that is an effect perhaps more negative than positive, if the flexure proceeds, as many still believe, from what is going on on the side least exposed to the light.¶

The effect upon vegetation of the non-visible calorific rays at the other extremity of the spectrum have been but little studied. According to the experiments we have on this subject, they would appear to have but little power over any of the functions; but it would be worth while to investigate further the calorific regions of the spectrum by employing Dr. Tyndall's process—that is, by means of iodine dissolved in bisulphide of carbon, which permits no trace of visible light to pass.

How interesting it would be to make all these laboratory experiments on a large scale! Instead of looking into small cases, or into a small apparatus held in the hand, and in which the plants cannot be well seen, the observer would himself be inside the apparatus, and could arrange the plants as desired. He might observe several species at the same time, plants of all habits, climbing plants, sensitive plants, those with coloured foliage, as well as ordinary plants. The experiment might be prolonged as long as desirable, and, probably, unlooked-for results would occur as to the form, or colour of the organs, particularly of the leaves.

Permit me to recall on this subject an experiment made in 1853 by Professor Von Martins.** It will interest horticulturists now that plants with coloured foliage are becoming more and more fashionable. M. Von Martins placed some plants of *Amaranthus tricolor* for two months under glasses of various colours. Under the yellow glass the varied tints of the leaves were all preserved. The red glass rather impeded the development of the leaves, and produced, at the base of the limb, yellow instead of green; in the middle of the upper surface, yellow instead of reddish-brown, and below, a red spot instead of purplish-red. With the blue glasses, which allowed some green and yellow to pass, that which was red or yellow in the leaf had spread, so that there only remained a green border or edge. Under the nearly pure violet glasses, the foliage became almost uniformly green. Thus, by means of coloured glasses, provided they are not yellow, horticulturists may hope to obtain at least temporary effects, as to the colouring of variegated foliage.

The action of electricity on vegetation is so doubtful, so difficult to experiment upon, that I dare hardly mention it; but it can easily be understood how a building constructed as proposed might facilitate ex-

* Senebier, "Mem. Phys. et Chim.," 2, p. 69; Tessier, Mem. Acad. Sc., 1783; Gilby "Ann. de Chimie," 1821, v. 17; Senecey, "Commentatio de lucis effectibus chemiis," in, 4to, Jenæ, 1828, p. 61; Zantedeschi, cited by Dutrochet, Comp. Rend. Acad. Sc. 1844, sem. 1, p. 853.

† As a proof of the persistence of the old opinion, I will quote a phrase of Professor Tyndall's in his most clear and interesting treatise "On Radiation," (London, 1865), p. 6:—"In consequence of the their chemical energy, these ultra-violet rays are of the utmost importance to the organic world." I do not know whether the author had in view the influence of the chemical rays over the animal kingdom; but, according to certain passages of Mr. Sachs, I doubt if they have more power over animals than they have over plants; but Professor Tyndall did not concern himself with these questions, he was content to explain admirably the physical nature of the various rays.

‡ The researches of Mr. Sachs first appeared in the "Botanische Zeitung," in they are collected and condensed in the remarkable volume entitled "Handbuch der Physiologischen Botanik," vol. 4, Leipzig, 1855, p. 1 to 46.

¶ S. Pogglioli, "Opuscoli Scientifici," quoted by Dutrochet, "Compt. Rend. Acad. Sc.," 1844, sem. 1, p. 850.

** The rather confused and questionable explanations, founded on the notions of Dutrochet, of the existence of a deoxidising power on the brightest side, clash with the fact that the blue, indigo, and violet rays, the least powerful for deoxidising tissues, are the most powerful in causing them to bend.

*** "Gelehrte Anzeige," München. 2 Dec., 1833.

periments on this subject. Respecting the action of plants on the surrounding air, and the influence of a certain composition of the atmosphere upon vegetation, there would be by these means a large field open for experiments. Nothing would be easier than to create in the experimental hothouse an atmosphere charged with noxious gas, and to ascertain the exact degree of its action by day and by night. An atmosphere of carbonic acid gas might also be created, such as is supposed to have existed in the coal period. Then it might be seen to what extent our present vegetation would take an excess of carbon from the air, and if its general existence were inconvenienced by it. Then might be ascertained what tribes of plants could bear this condition, and what other families could not have existed, supposing the air had formerly had a very large proportion of carbonic acid gas.

Until horticulture can supply physiology with such convenient means of experiment, it, in the meantime, advances descriptive botany by the valuable publications it issues. The greater part of the old works with plates, such as "Hortus Pystettensis," "Hortus Elthamensis," &c.; also those of Ventenat, Cels, Redoute, &c.; the "Salicetum" and "Pinetum" of the Duke of Bedford; and more recently the "Rhododendrons of the Himalaya," by Dr. Hooker; the works of Bateman, Ponsatore, K. Lehmbach, on Orchids; and many others I could name, would never have been published, had there not been rich amateurs either to edit or to buy them.

It is horticulture that has given us the longest series of illustrated journals that have ever been published; and here I must do justice especially to the English horticulturists. No doubt the science of our time requires a larger amount of analytical details than is contained in the plates of the "Botanical Magazine," "Botanical Register," "Andrews' Repository," "Loddiges' Botanical Cabinet," "Sweet's British Flower Garden," "Paxton's Magazine and Flower Garden," and other English journals; but what a number of forms are thus fixed by the engravings in these books, and what a fund of valuable documents for consultation they afford! One cannot fail to admire the "Botanical Magazine," commenced in 1793, continued from month to month with an exemplary regularity, and which is now at its 5,580th plate. Not only has it always represented rare and new species, but it has ever been conducted on a simple and uniform plan, which renders it convenient to consult.

The series of plates is unique from the very beginning. Each plate has its number, and each article of letter-press refers only to one plate, by which means the quotations from the work are rendered brief and clear. Many editors have not understood the advantage of this simple arrangement. They have varied their titles, their series, their pagings; they have affixed to their plates numbers, then letters, then nothing at all; the end of which is (and this ought to serve as a warning for the future), that the more they have altered and complicated the form of their journals, the shorter time have they lasted.

How is it that the purely bibliographical details cause in us such sad recollections? Of the men just mentioned, who have rendered such eminent service to botany and horticulture, England has lost three during the year 1865—Sir Joseph Paxton, Dr. Lindley, and Sir William Jackson Hooker.* I should certainly fail in what is expected of me if I did not express, in the name of the foreigners attending this meeting, our deep regret at such serious losses. We know them all by their writings, and many amongst us have known personally the distinguished men I have mentioned. Their names follow us at each step in this the scene of their labours. If we admire the boldness of construction of the iron domes that characterise modern buildings, we think of the Crystal Palace, of Chatsworth, and of the humble gardener who became a great architect. If we visit the beautiful establishment at Kew, we see everywhere around us proofs of the indefatigable activity of Sir William Hooker. Lastly, if we ask the origin of the garden of the Royal Horticultural Society at Kensington, we are told it is only a development of that at Chiswick, where Lindley stood pre-eminently by his knowledge and his energy; and of that Society were botanists of my age found in their youth such valuable encouragement in their studies.

The names of Sir William Hooker and of Dr. Lindley, thanks to their special works, will ever remain distinguished in science. These two botanists have, moreover, been directors of horticultural journals, and of great horticultural establishments, and since their influence has been so fully acknowledged by practical men, I shall have little trouble in showing that science is as useful to horticulturists, as horticulture is to botanists—and this will form the second part of my discourse.

SECONDLY.—THE ADVANTAGE OF BOTANY TO HORTICULTURE.

The principles of vegetable physiology are what horticulturists and agriculturists usually study in books on botany. They do not always find direct answers to their questions; but they can draw from them certain rules, certain ways of experimentalising and reasoning, which saves them from falling into many errors. Should some ridiculous idea be promulgated by some ignoramus or charlatan, it is by an appeal to the general rules of physiology that a practical man may at once reject them, or at least, hold them in distrust. On the contrary, in-

novations, if in harmony with the general principles of the science, may be, and I will even say, ought to be readily accepted.

Do not let us put too much faith in the lucky results of experiments made absolutely by chance. It is with some of these experiments as with dreams and presentiments—if they come true once in a thousand times they are talked about, otherwise they are passed over and forgotten. Besides, it must be said, men nearly always are guided by theories; but the theories of the ignorant are often absurd and without foundation, whilst those of educated men are based on probabilities or on an accumulation of facts.

Conjointly with physiology, botanical geography shows the distribution of plants all over the globe, their struggle with the elements, their migrations, and already raises a portion of the veil which covers the obscurity of their origin. All this ought to offer a real interest to horticulturists. We are beginning to have the power of expressing in figures the effect of each climate upon vegetation; consequently, the possibility of a given species enduring the mean or extreme climatal conditions of that country to which it is desired to introduce it. Already we can show, in the clearest manner, the analogy between the vegetation and climate of certain regions widely separated the one from the other, and point out in which cases new attempts at cultivation should be tried or where they should be discouraged. A celebrated geologist was able to say beforehand, There is gold in such a part of New Holland; and gold was found there. We can also say, the Olive tree and the Cork Oak will succeed in Australia; the eastern and temperate region of the United States is favourable to the growth of Chinese plants, more particularly to that of tea; and we can assert that that part of America included between San Francisco and the Oregon territory will, one day, supply wines as varied and as excellent as those European ones produced between Portugal and the Rhine.

It is a singular fact that the two principal beverages of the civilised world, wine and tea, which produce similar stimulating effects, but which to a certain extent are the substitutes one for the other in different countries, present also in the mode of cultivating them the most marked resemblances and differences. The Vine and the Tea-plant succeed best on stony, barren hill sides, of which they sometimes increase the value a hundredfold. According to the exposure, the soil, the cultivation and manner of preparing the produce, wine and tea are obtained of unquestionable excellence; whilst the neighbouring crops, but a short distance off, may be more or less ordinary in quality. The two shrubs require a temperate climate, but the Vine needs heat and no rain during summer, whilst the Tea-plant requires rain and but little summer heat; the result of which is, that these two species are almost geographically incompatible. Vine-growing countries will never produce tea, and vice versa.

But, you will say, these examples belong rather to agriculture, and concern neither botany nor gardens. I maintain the contrary. It is science, in the present day, which points out what plants to cultivate, and into what countries to introduce them. Horticulture makes the trial with infinite pains. If successful, the young plants are submitted to the less careful treatment of agriculture. Before the happy introduction of Cinchonas into British and Dutch India could be effected, botanists were required to collect, distinguish, and carefully describe the various species of American Cinchonas; horticulturists were then called on to make cuttings, gather the seeds, raise the young plants, transport and establish them in another part of the world; and so at last they were passed over to the care of the agriculturist. The Coffee plant did not spread gradually from Arabia to India, from India to Java; nor was it the American colonists who brought it from its original country to their *fazendas* or *haciendas*. The shrub was first described by botanists, and was afterwards introduced by the Dutch into a garden at Batavia; from thence it was taken to the Botanical Garden at Amsterdam, from whence a specimen was sent to the king of France in 1714. De Cien, a naval officer, transplanted it from the garden at Paris to the French colonies in America. A multitude of such instances might be named. In the present day science has progressed, practical men avail themselves of it, governments and nations have abandoned those mistaken ideas in accordance with which it was supposed that a cultivation advantageous to one country was injurious to others. Hence we may hope to see, before long, useful species planted in all regions where they can thrive, to the great advantage of mankind in general.

One of the most evident effects of science has been to create in the horticultural public a taste for varied and rare forms. Formerly in gardens there were only to be found certain kinds of plants which dated back to the time of the Crusades, or even of the Romans. The discovery of the New World did not produce a change in proportion to its importance; perhaps because horticulturists did not travel enough, or acquainted themselves with those countries whose species were most suitable for cultivation in Europe. Botanists, fortunately, were more ambitious. Their collectors were numerous and daring. They enriched their herbaria with an multitude of new forms, and published works upon exotic plants, such as those of Hernandez, Kumphius, Sloane, &c. The immense variety in the forms of plants was thenceforth recognised, and in point of taste the elegant simplicity of the primitive flowers was able to vie with the gaudiness of the double ones. Then came the reign of Tulips and Peonies in flower-gardens. Curiosity, that great incentive to all science, having penetrated horticulture, the change in gardens became rapid. Instead of a few hundred species such as were cultivated at the commencement of the last century, there

* Since these lines were in the printer's hand British science has sustained a severe loss in the death of the truly amiable and learned Professor W. Harvey, of Dublin, so well known by his works on Ager, and on the Botany of South Africa. I cannot refrain from expressing our sense of this great bereavement.

are now 20,000 or 30,000 to be found in most of the present catalogues. The single family of Orchids has probably more different representatives in our hothouses than was the case with all the families of plants put together a hundred years ago. Fashion, united to the present curiosity of amateurs, causes, from time to time, old plants to be abandoned for new ones; and thus the entire vegetable kingdom will ultimately pass under the observation of civilised man.

What would horticulturists do, amidst this invasion of thousands of species, had not botanists devised convenient plans of classification and nomenclature? The families, genera, and species, have all been arranged in books, just as the districts, streets, and numbers of the houses are in our great capitals.—with this superiority of method, that the form of the objects indicates their place—as if, in looking at a house in a town, one could discover, at a glance, to what street and to what quarter it belonged. The plan of giving a single name to each species, besides its generic name, together with the prohibition of changing names without due reason, and of giving the same appellation to two different species, or to two genera, far exceeds our plan of distinguishing individuals. How much it would simplify our intercourse with men, and facilitate our inquiries, if, in the whole world, the members of one family only bore the same name, and if each individual had but one christian name, differing from those of the other members of his family. Such is, nevertheless, the admirable plan of nomenclature that science has provided for horticulturists, and which they cannot too much appreciate and respect.*

THIRDLY.—THE BENEFICIAL EFFECTS OF THE ASSOCIATION OF BOTANY WITH HORTICULTURE.

The pursuit of horticulture demands books and herbaria, as that of scientific botany requires cultivated, living plants. Thence the necessity, which is more and more recognised, of bringing together the materials for comparison in the same town, the same establishment, and even under the same administration, organised so as to facilitate the use of them. How many institutions in Europe, either private or public, would be benefited by this arrangement! How many towns and countries are now deficient—some in libraries, some in herbaria, some in respect to horticulture. Professional men proffer their complaint; let us hope that public opinion may end by listening to them.

The bringing together the means of study, I have said, is desirable. Not less so is the interchange of ideas and impressions, both of botanists and horticulturists. Each of these classes must clearly have distinct characteristics; but the one should be influenced by the other. By these means, some too-retiring dispositions may be brought out, and certain dormant powers developed. Horticulture, for instance, has a commercial tendency which may be carried too far. Charlatanism may slide in amongst flowers. Botany, on the contrary, is a science, and consequently rests on the investigation of pure and simple truth. A horticulturist who allows himself to be influenced by a scientific spirit, necessarily frees himself from over-selish tendencies. Natural history, on its side, by reason of the perfection of its method, its nomenclature and its minute observations, has something technical and dry about it, which contrasts with the grandeur of nature and with the sentiment of art. It is for horticulture, combining, as it does, the planning and the decorations of gardens, to develop the aesthetic faculties of the savant, as of the world in general. A lovely flower, beautiful trees, a splendid floral exhibition, excite a sort of admiration, and even enthusiasm, similar to the effects produced by music or painting.

The powers of the German composers of modern days, and those of the Italian painters of the sixteenth century, are justly extolled; but may it not also be said that in point of art they are equalled in their way by the beautiful parks of old England? The feeling of harmony in form and colour, is it not also studied in them? The effect of contrast, is it not skilfully managed? The gradual transition from architectural to natural beauties, is it not treated in an admirable manner? Yes; decidedly the English landscape gardeners are poets; they have drawn from the same sources of inspiration as the most national writers of their country, and that source is the appreciation, so universal in England, of the beautiful, in an aspect of nature which is elegant and attractive, though somewhat severe.

Thus, gentlemen, for the development of our talents, as well as for our actual benefit, Art and Science keep pace together. Let us rejoice over their union, rendered conspicuous to-day by this congress of botanists, held in connection with a great floral exhibition; and after

* Two years ago I made a request to the *Fédération des Sociétés d'Horticulture Belges*, which appears to have been favourably received, and it may not be useless to repeat it here. It consisted in begging the horticulturists who obtain new varieties not to give them botanical names, with a Latin designation, but merely arbitrary names of quite a different nature, in order to avoid confusion and useless researches in books. For example, if they called a *Calecolaria* *Sebastopol*, or *Triomphe de Gand*, every one would understand it meant a garden variety; but if they named it *Lindleyi*, or *mirabilis*, the student would take it to be a botanical species, and would search for it in scientific works, or in the *Floras of Chili*; and botanists, happening perhaps to mistake it, would add it to the end of the genus in their books as a species imperfectly known. The more horticultural names differ from Latin ones, the better it is, unless they can be appended to the scientific nomenclature; as when we say *Frassica campestris olifera*, instead of, shortly, *Colza*.

† The Botanical Gardens at Kew afford a fine example of what should be done, either on a large or a more modest scale, in many towns where the means of study are yet inconvenient or incomplete.

these general observations—perhaps rather too protracted—let us enter upon the consideration of those more truly scientific subjects, in which many among you are no doubt disposed to take part.

THE BANQUET AT GUILDHALL.

On Tuesday evening a grand banquet took place at the Guildhall, at which the Right Hon. the Lord Mayor presided. Upwards of 550 were present, and amongst them were Viscount Powerscourt; Sir Broke Middleton, Bart.; Right Hon. R. C. Nisbet Hamilton; M. A. De Candolle, of Geneva; Professor Koch, of Berlin; Professor Reichenbach, of Hamburg; Professor Caspar, of Konigsberg; Professor Morren, of Liège; M. Schulz Bipontinus, of Deidesheim; M. Meissner, of Parsle; M. Weddell, of Poitiers; M. Van Houtte, of Ghent; M. A. Verschaffel, of Ghent; M. Lindén, of Brussels; Sir Wentworth Dilke, M.P.; Dr. Hogg, Dr. Maxwell Masters, Mr. Kelk, M.P.; Mr. J. Clutton, Mr. Sheriff Gibbons, Mr. Alderman Besley, Mr. Pender, Mr. E. A. Bowring, C.B.; Mr. Micholls, Mr. Samuel Morley, Mr. George Godwin, F.R.S.; Mr. J. J. Blandy, Mr. W. H. Dixon; Mr. G. W. Johnson; Mr. T. Moore; Messrs. Veitch, Lee Standish, Bull, Williams, Paul, Waterer, Low, Wendland, Fortune, and Captain Walker.

Grace having been said, and the "loving cup" sent round, the Lord Mayor gave the first toast, "Her Majesty the Queen." He said: "On the throne of this peaceful and constitutional country there sits a Royal lady, who reigns not alone over her subjects, but in the hearts of her people. It is amongst the happiest of our customs, that upon these festive occasions we drink to the health of Her Majesty, wishing that her reign may be a long and happy one, and that her people may be prosperous, contented, and free."

The Lord Mayor then proposed "The Army, Navy, and Volunteers." He remarked that the bravery and exploits of the Army and Navy were matters of history. No one could contemplate what was passing in neighbouring countries without the deepest emotion. There was not a heart that did not sympathise, not a tongue that did not utter the hope that the miseries and horrors of war might be averted. This was the earnest prayer of every Englishman, and he trusted that it might never be uttered in vain.

Admiral Sir GEORGE BROKE MIDDLETON, Bart., in returning thanks made some remarks on the recent events in South America. Though on such an occasion as the present he was unwilling to introduce a subject which would direct the thoughts of those who listened to him to the horrors of war, yet the news that had recently been received from a distant part of the world had cast a shadow over the profession to which he had the honour to belong; and as that profession had been most ungenerously attacked during the last few days, he felt himself bound to say a few words in its defence. He alluded to what had been said in reference to the bombardment of Valparaiso. He had the honour to call Admiral Denman his friend, and he knew him to be one of the most high-spirited and gallant officers in the service.

The Lord Mayor next gave "The House of Lords and the House of Commons." There never was a period in the history of this country he said, when there was a greater sympathy than existed at present between the House of Lords and the people; and with regard to the House of Commons, he thought he might safely say that the intelligence and independence of this great country were fairly represented in that House.

Viscount POWERSCOURT after having made a few remarks on the present position of matters in the Houses of Parliament, said that he could not resume his seat without congratulating the Committee of the International Horticultural Exhibition on the very beautiful and highly successful Show they had witnessed that morning—an Exhibition that must have afforded the greatest pleasure to all who took the least delight in horticulture.

Sir C. W. DILKE, Bart., the Chairman of the Executive Committee, proposed "The health of the foreign visitors and the President of the Botanical Congress." This he said had been the most remarkable horticultural Exhibition that had ever been held, and he was happy to add that it had been most successful in the number of visitors it had attracted. As a whole it was an Exhibition that had never been equalled, and he doubted whether it could ever be surpassed.

The toast was received with loud cheers.

Professor DE CANDOLLE, in responding, said:—"The words of welcome which we have just heard, and the fact that my name has been mentioned in so kind a manner, make it incumbent on me to thank you in the name of the strangers present. You have done them great honour by inviting them to this banquet, and, indeed, since their arrival they have not ceased to receive, in private as well as in public, a welcome of which they cannot but be proud, and which will leave many pleasant remembrances in their minds. This morning the Prince and Princess of Wales and the Princesses of the Royal Family condescended to express their regret that they could not accept the splendid hospitality over which the chief of the illustrious city of London presides; and the hon. baronet who has assisted in all these preparations with a zeal which has been crowned with success, has been kind enough to propose the toast. The only persons who are to be pitied in all this are those botanists and horticulturists who may have desired to come to London, and who have been prevented from doing so either by their public duties or by the unfortunate state of affairs now existing on the Continent. But let us put on one side these personal considerations, and let us rather congratulate ourselves

on the prosperous state of the sciences and their applications, and particularly in the progress of Horticulture, of which this International gathering furnishes a proof. Our age is in this respect a great age, Horticulture has been pushed to an extraordinary degree of perfection, and the natural sciences have also advanced. What science wants, above all, is liberty—not only political liberty, which is to a certain extent very necessary; but, above all, that liberty which is accorded to each individual by public opinion. We have seen nations and ages where, under an absolute monarchy, there has been a great deal of liberty of thought; and *vice versa*, free countries in which public opinion has exercised an actual tyranny over individuals. Those who seek for scientific truth require to be protected by the public, even more than by a free political system. All the world ought to know the advantage of toleration of opinion, and public reprehension ought only to fall on bad faith. Science prospers when national institutions and public opinion allow it freedom. At the present time horticulture flourishes more particularly in the West of Europe, in England, Belgium, and Holland; and in some cities, such as Paris, Berlin, and Hamburg. Evidently a climate offering neither extremes of cold, nor heat, nor dryness, is favourable to its development. Evidently, also, the intelligent and pain-taking peoples of these western lands naturally give themselves to the minute details of cultivation; but there is still a condition which overrules all. Horticulture, carried to a certain extent, is a luxury. It supposes riches, and there is no extent of country more generally rich than Western Europe on either side of the Channel. Will International Horticultural Exhibitions spring up in the future on that arena? We must hope for it as well as for a more important object—peace, for war devours men as well as capital. Imagine to yourself (said M. De Candolle), what is the cost of the millions of soldiers at the present day massed together on Continental Europe. You will find, perhaps, that with their pay for a single day we could construct a conservatory reaching from Paris to Berlin. And here is a piece of advice which may be given beforehand to the horticulturists of the east and south of the Continent—not to make an insignificant imitation of English, Belgian, or Dutch culture, but rather to create a new system of horticulture as different from these as possible, suitable to their particular climates—a system of horticulture having for its foundation the plants of Asia, Africa, and Australia, capable of supporting heat, cold, and dryness. In making efforts in this direction they will do something new and remarkable, and the horticulturists of the west will go to see the exhibitions of eastern and middle Europe with the same pleasure that they visit in the present day their own exhibitions." M. De Candolle concluded by again thanking the assembly for the kindness which they had shown to the foreign visitors.

The Right Hon. C. NISBET HAMILTON, in proposing "Success to the International Horticultural Exhibition and Botanical Congress," said: "He had no doubt that those who had witnessed the Exhibition were highly gratified by what they had seen. For his own part he must confess, that although he had seen numerous exhibitions of flowers in many parts of the world, the present Exhibition surpassed them all. Lord Bacon had said, nearly three hundred years ago, 'God first planted a garden, which, indeed, is the parent of human pleasures; it is the greatest refreshment to the spirits of men, without which buildings and palaces are but gross handiwork.' This, it should be remembered, was an expression employed by one of our greatest philosophers. In England horticulture was pursued alike by the greatest and noblest, and the poorest and humblest in the land; and he believed that it had a tendency to elevate the mind. Although, he said, we are proud in this great country of our manufacturing and commercial prosperity, we are proud also that such a meeting as the present can be held under the presidency of the chief magistrate of the City of London. It was gratifying to observe the taste for floriculture that exists among the people, as is evidenced in many of the crowded lanes of the metropolis and other densely populated places, by the care that is taken of a solitary plant, such as a Geranium or a Fuchsia. Referring, again, to the Exhibition of the morning, he would say that Brussels and Amsterdam had had their International Exhibitions, and London had followed the example set by those places; and he hoped he might say without offence, that in this Show we had been enabled to surpass those that had gone before. He trusted that although this was the first Show of the kind that had taken place in London, it would not be the last."

Dr. Hogg briefly responded.

Sir C. W. DILKE proposed "The health of the Lord Mayor and the Corporation of the City of London."

The Lord Mayor said in reply: "My Lords, Ladies, and Gentlemen—Different men, according to their different humours, have formed various plans for bringing the whole human race under one head. A tyrant wished that all mankind might have one neck, that he might strangle it. A gallant bard grieved that 'fair womankind could not reserve their smiles for him alone; and I, by an inverse process of reasoning, would give my place to-night could I be blessed with a thousand warm and varied tongues wherewith to bid you, from 'heart to very heart,' one and all a sincere and earnest welcome. The gentlemen who honour us with their presence here to-night have invited us to view the most interesting, the most marvellous, and the most wonderful Exhibition the world has ever seen. I think I may call it the queen of exhibitions. The right honourable gentleman has told us that Lord Bacon says, 'The Almighty Father first planted a garden.' A garden is, and has been, the foundation of religion—of poetry—of all

that is brightest and holiest amongst men. What is there on earth that so much contributes to our delight, to our enjoyment, as a garden? A garden is health—a garden is wealth—a garden is happiness. What is more refreshing, more delightful than the sweet fruits of earth? What is more fragrant than the breath of flowers? It has been said that Nature, so fair and bounteous in herself, needs not the hand of man to train and cultivate her; but Nature in every shape requires cultivation. The luscious Peach, the clustering Vine, the fragrant Myrrh, the Rose divine, abundantly illustrate the truth of this. In this age of great competitive and cosmopolitan industry our neighbours are doing with their flowers what we do with our sons—urge them to take honours at home, and send them to gain laurels abroad. On the part of this municipality, I beg to assure you that we hold out to you, one and all, the right hand of fellowship—that we recognise the great merits of art, of science, and of literature, and we look upon this Exhibition as one of the happy and peaceful triumphs of our time. May it flourish, not only for the present, and for our sakes, but may it flourish for the future."

Prof. Koch proposed "The Executive Committee of the Horticultural Meeting," and Sir D. Cooper returned thanks.

Mr. C. DILKE having proposed "The Lady Mayoress and the Ladies," the Lord Mayor, in acknowledging the toast, said that the Lady Mayoress desired him to say that the sight she had seen that day was one of the most gratifying of her life.

During the evening the band of the Grenadier Guards, under the direction of Mr. D. Godfrey, played a choice selection of music in the gallery.

DEJUNER AT MESSRS. VEITCH'S.

BEFORE commencing the formal business of the Congress on Wednesday, the foreign botanists and gardeners were invited by Mr. Veitch, the English horticulturist, to a magnificent déjeuner at the Exotic Nurseries, Chelsea. The foreign guests were met by a distinguished company of their English counterparts, and the occasion was one of much interest. Among the principal visitors were—Professor Lecoeq; Professor Triand, of Paris; Professor Koch, of Berlin; Professor Morren, of Liège; Dr. Reichenbach, of Hamburg; M. Barillet, Paris; M. Vilmorin, Paris; M. Popin, delegated by the French Government; M. Sello, Potsdam; M. Nilsson, Naples; Baron Oxy, Antwerp; M. Linden, Brussels; M. Van den Recke, M. Willink, Amsterdam; M. Krelage, Haarlem; Viscount Foreville; Sir Wentworth Dilke, Bart.; Sir D. Cooper, Bart.; Rev. Joshua Dix; Rev. Mr. Berkeley; J. McSah, Esq., Edinburgh; Dr. Moore, Dublin; Dr. Hogg; Dr. Masters; G. Eyles, Esq.; J. Liddell, Esq., &c. Mr. Veitch, senior, presided. Among the toasts drunk was one to "The Foreigners present." To this the representatives of France, Belgium, Holland, Germany, and Italy responded. Several of these gentlemen spoke in English, and expressed their admiration at the pre-eminence of British horticulture. Mr. J. G. Veitch, who has travelled in Japan, Australia, and other regions searching for new plants, many of which he has successfully introduced to cultivation, replying to some complimentary remarks of one of the foreign professors present, spoke in French. Sir Wentworth Dilke, as Chairman of the Executive Committee, returned thanks for the observations made complimentary to this country. The visitors inspected Messrs. Veitch's valuable collection of plants, the most notable of which, however, are now being exhibited at the Show. The whole occasion was marked by the most cordial feeling, and was a matter of much gratification to those present. Each guest, on leaving, entered his signature in a book, and received from Mr. Veitch his *carte-de-visite* as a souvenir.

DINNER AT ST. MARTIN'S HALL.

ON Thursday evening upwards of five hundred gentlemen sat down to dinner at St. Martin's Hall, Lord H. G. Lennox, M.P., presiding.

Among those present were Sir Wentworth Dilke, Bart., the Rev. Joshua Dix, Rev. S. R. Hole, Dr. Hogg, Mr. T. Moore, Mr. C. Edmonds, Messrs. Lee, &c.

On the removal of the cloth, the CHAIRMAN said the first toast on the present occasion was one which all Englishmen delighted to honour. For many years they had had the happiness of being under the most constitutional of Sovereigns, a Lady whose private life would bear comparison with that of any other in the land. These were great blessings, and would always secure that, wherever the toast was proposed, it would be received with enthusiasm. He was one of those who thought that, possessing such blessings, they could not do better than enumerate them on every possible occasion.

The CHAIRMAN next proposed that of the Prince of Wales, with that beautiful Danish Rose which had been transplanted to this country, and who, they trusted, might long flourish on British soil, and the other members of the Royal Family. Prince Alfred was a true Britisher. He had seen him on board of ship in the Mediterranean, where he took all his watches and performed all the duties as the sons or brothers of those present would have done if they had been in that position. He trusted also that they would give an extra cheer for the Princess Helena, who was about to be married, but who, he was happy to say, was not about to leave England, but to remain here to be a solace to her widowed mother.

The CHAIRMAN next proposed "The Army, Navy, and Volunteers," associating with it the name of The Maceod of Maceod, who briefly returned thanks.

The CHAIRMAN said he must now crave the indulgence of the meeting while he proposed the toast of the evening. It was a toast which would naturally tax the powers of a chairman under any circumstances, for in itself it possessed an intrinsic interest to all present. He trusted that that interest would act as a cloak to cover the deficiencies of him in whose hands it had been placed. The toast, as placed in his hands, was "Success to the Promoters of the Horticultural Exhibition and the Botanical Congress." He himself was one of those promoters, and it would be judicious to propose success to himself. He would, therefore, with the permission of the meeting, substitute "Success to the Horticultural Exhibition and the Botanical Congress now sitting in London." From the first time this scheme was broached, he had given it his most

cordial support, because he thought it was simply a grateful return for the courtesies which British horticulturists had received in Belgium, France, and Holland. In the next place, he supported it because he believed it tended in a great degree to foster and to increase in this country a love of horticulture, and a taste for the growth of flowers. There was no sentimentalism about that. It was an undisputed fact that a love of horticulture and a taste for floral creations tended to refine and humanise the best feelings of man. Let any one go to Battersea Park, or to Kew Gardens, and see the artisan who, confined for six days by his work, escaped on the seventh to admire the wondrous creations of nature displayed there, and he would not fail to come back with the strong conviction that through these works a man's mind must be directed to Him who was the Creator of them all. This, then, was an essentially practical matter. As a member of the Council of the Royal Horticultural Society, it had devolved upon him to receive and to read communications without end from the clergy of various denominations in this great metropolis, praying that the Society would afford them assistance in providing prizes for window gardens in the poor and densely populated districts of London in which they laboured. One and all of these gentlemen stated, that in giving this aid they would be doing an immense amount of good—an amount of good which would be incalculable. In consequence of these representations they did establish prizes, and last year they expressed their willingness to co-operate with others in providing additional prizes; but, owing to the illness of a gentleman who undertook the management of the matter last year, the subject had lapsed, only, however, to be revived next year. They had established prizes in the shape of silver and copper medals, for the best cultivated gardens in the largest camps in England and Ireland; and they had received the warmest testimonials from generals and officers, who had agreed in assuring the Council how much what they had done had contributed to the morality and the good order of the regiments where such prizes had been given. Horticultural science had this great advantage, that from the moment a child commenced it, flowers literally grew under his feet. Even the greatest tyro in the study could never feel lonely in the secluded lanes or the wildest districts of the country, for wild flowers would crop up around him on every side, giving him ample food for meditation, and so turn out to be his kindest and most genial friends. Thus much, then, for the reasons which had induced him to give his hearty co-operation to this scheme, and was it not a scheme that had proved a decided success? To his mind, there could be but one answer to that question, and that was a most emphatic affirmative. It was an attempt on their part to rival, with all possible kindness, similar undertakings that had been inaugurated in various parts of the Continent. He regretted that in the magnificent display they had witnessed there were not more productions from foreign countries; but, on the other hand, he rejoiced to think that both in that room and in another place there were professors of botany and horticulture who had come over from foreign lands to testify their sympathy with the efforts which had been made here. Had any one, he would ask, ever seen more beautiful specimens of horticulture than those which had been displayed? Had any one ever seen more successful fruits of unwearied patience than the horticulturists of this country had furnished? Had any one ever seen a collection which had been displayed in a more advantageous or picturesque manner? Strolling down its long avenues, it really appeared that these beautiful flowers had been placed there by some magic hand, and that it must be one of those happy places in which they were told in their childhood fairies delighted to dwell. The next point they had to consider was to whom those great successes which had been achieved were due. In the first place thanks were due to the gardeners of this country whose public spirit, enthusiasm, unwearied zeal, and great ability, together with their great disinterestedness in trusting plants of so valuable a nature to all the chances and changes of temperature, could not be too highly commended. Next, thanks were due to a public-spirited gentleman, Mr. Ormsen, who had seen that everything tender was warmly housed; and lastly, thanks were due to Mr. Gibson, who had been selected by the Executive Committee to arrange the grounds. Let them for a moment pause to consider the enormous strides this matter had made during the last few years. Some of those present would remember the first Show, how small and comparatively insignificant it was; now the Show extended over 31 acres; and at the Paris Exhibition, which it was proposed to hold next year, so confident were Frenchmen of the resources of England, and the public spirit of English gardeners, that they had apportioned 31 acres of their space to England—a space which they expected English gardeners to fill. They were assembled on the anniversary of that distinguished Swedish naturalist, Linnæus. In one sense that was to be regretted, because the gentlemen who composed the Society bearing his name were holding a banquet that night, a circumstance which deprived them of the support of many of the professors of botany and horticulture, who otherwise would have been amongst them. In the latter part of the last century that great man visited this country. If he had gone to the Exhibition and seen those beautiful Azaleas, had looked upon the colour-follage of the plants which vied with them, or those Orchids, grotesque in form but brilliant in colour, would not thoughts have occurred to that scientific mind which would have opened to him a new world of inquiry? But while the gardeners of England had done well they must not suppose that he (the Chairman) was going to tell them off by saying that they had done all they could. They had done nothing of the kind. He trusted that if he were spared until next summer, he should see the English gardeners over in Paris, and that they would show to the French nation what they could do, and that they would not be afraid either of transit by land, or passage by water, so that they might rival their friends abroad. He knew that many of their foreign friends were present that evening, so he would conclude his remarks with an allusion specially addressed to them. He would say to them that the great festival which they were now celebrating was a mark—only a feeble mark it might be—of their deep gratitude for the cordial, hospitable, and friendly manner in which they received the British horticulturists when they were abroad. He would tell their foreign visitors that they were heartily welcome in this country, and he trusted that they would accept the reception which had been given to them as a feeble expression of the gratitude of Englishmen for past kindnesses. Above all they would declare to their foreign friends that night, whether from France, Holland, Belgium, or anywhere else, that the wish of the English people was that they might cast aside old rivalries and old antiquated jealousies, and do nothing but compete with one another in the most friendly contests—not on the battle field, but in the promotion of all that tended to the advancement of science, of

commerce, and of art. He would propose "Success and prosperity to the Horticultural Exhibition, and to the Botanical Congress, and might the great objects sought to be accomplished be abundantly realised."

The toast was drunk with loud applause.

Mr. W. PAUL, in responding, stated that the origin of this movement had been so well explained, that he need not further advert to it. For its success it was greatly indebted to Mr. Moore, who had done his very utmost to secure it. They had succeeded in bridging over a chasm between horticulturists and botanists which no doubt would be turned to favourable account hereafter. He maintained that Horticulture was both an art and a science—an art as pursued from the decorative point of view, a science as regards the production of fruits and flowers. Gardening as an art had produced men of whom every Englishman had reason to be proud—a Prince, a Knight, a Gipsin, a Kepton, a Paxton, to say nothing of living men; and the highest and wealthiest in the land, the most refined and intellectual, take a pride and pleasure in the decoration of their gardens. Horticulture as a science has so many true sons that it would be impossible to name even the most prominent. Is there no science in producing with unerring certainty, alike amid the snows of winter and the heat of summer, those splendid fruits and flowers, without which the entertainments and assemblies of this great nation would be shorn of half their enjoyment? It is too close upon the event to estimate its results. Of this, however, we may be sure, that while Botany and Horticulture are promoted by it, it will give fresh life and a wider development to an important branch of natural industry.

The Rev. J. DIX said no doubt at the present time the horticultural world was wide awake; it had been asleep some time. He had been asked to propose as a toast, "The Royal Horticultural and Botanic Societies." In all sincerity of heart he had advocated the claims of the Horticultural Society, and since he became a member of it he had gone through many difficulties. He had been called an obstinate opposer, but he had found that what was called obstinacy had been productive of very good results. When he mentioned the great success of their Tuesday meetings he thought he need say no more. They must remember that their operations were under the searching and scientific eyes of many visitors. As he looked down the tables before him he saw gentlemen who were the very sinews of horticulture, and he had no doubt they would experience the best results if members of the Society would look after their own interests. He proposed "The Horticultural and Botanic Societies," with which he would associate the names of Mr. G. F. Wilson, and Sir Walter Stirling.

Sir W. STIRLING, and Mr. G. F. WILSON returned thanks.

Dr. DAVID MOORE gave some account of the progress of horticulture in Ireland.

Mr. J. G. VEITCH proposed "The health of their kind friends, the distinguished Foreign Visitors." It was on foreign soil that the first Exhibition of this kind took place—viz., at Brussels, and in England they were only carrying on what was begun there. He assured the foreign visitors that although their reception had not been one of ostentation or splendour, it has been a hearty and a welcome one.

M. VAN GEERT, jun., acknowledged the toast in appropriate terms.

Mr. JOHN LEE proposed the health of "Friends from the Provinces," to which the Rev. S. KEYSOLDS HOLE, Vicar of Caunton, Nottinghamshire, and Mr. A. DICKSON, of Chester, appropriately responded.

"Friends from Scotland and Ireland," was proposed by Mr CHARLES TURNER, Mr. DAVID MITCHELL returning thanks.

Sir C. W. DILKE, Bart., expressed his regret that he was not present earlier, but in common with some friends who had been at the Linnean Society, he had determined to be amongst them as soon as possible. He was always anxious to give as much assistance as possible to the cultivation of horticulture and botany. He felt that it would have been impossible for him to attend and not propose the toast which he would ask the company to drink with all the heartiness it deserved—"The Health of the Chairman, Lord Henry Gordon Lennox."

The toast was drunk with enthusiasm.

The CHAIRMAN, in acknowledging it, said he asked himself why he had been invited to preside. It could only have been because he felt a deep interest in the promotion of the sciences they were met to serve. The position he held had many advantages, but his sole desire was to make them conducive to the general welfare of the Society.

The company then separated.

One of the best evidences of the entire success of the Exhibition is the unanimous wish of the Committee and exhibitors to prolong the time during which it shall be open to the public. There is a general reluctance to have such an artistic accumulation of beauty dispersed, and we are very pleased that it is to remain in its integrity until Thursday next. The Royal Horticultural Society have also liberally consented to have their garden gratuitously open to the visitors of the Exhibition during the time.

We think the Committee would confer a great benefit as well as afford great pleasure to a multitude, if on the last day they allowed four to be admitted for a shilling. Thousands would avail themselves of the privilege who would not like to spend the shilling on themselves alone, yet could not afford the same sum for their wives and children.

The amounts of cash taken at the doors up to Saturday night were—

Tuesday (£1 admission) £392	Friday (1s. admission) .. 4150
Wednesday (10s. do.) .. 1222	Saturday (2s. 6d. do.) .. 810
Thursday (2s. 6d. do.) .. 1798	

These amounts are quite irrespective of the sale of tickets by the agents, which is not yet ascertained.

SOME HINTS AS TO THE ARRANGEMENT OF FLOWER BEDS AND BORDERS.

(Continued from page 302.)

No. 29. Centre, *Pelargonium Stella*; next row, *Tropaeolum Elegans*; third row, *Verbena Velvet Cushion*, with an edging of *Gnaphalium lanatum* next the grass. The *Gnaphalium* must be kept closely pegged down and pinned in, otherwise it will overgrow the *Verbena*.

No. 30. Centre, *Verbena venosa*—the plants of this should be well established; 2nd row, *Geranium Flower of the Day*, with the flowers left on; 3rd row, *Amaranthus melancholicus ruber*, with an edging next the grass of *Golden Chain Geranium*.

No. 31. Centre, *Calceolaria Sparkler*; 2nd row, *Geranium Christine*; 3rd row, *Iresine Herbstitii*, with an edging of *Gazania splendens*. This bed would present a very dazzling effect.

No. 32. Three or four feet of the centre should be filled with *Coleus Verschaffeltii*; next to this a two-foot band of *Viola cornuta*, with an edging of *Arabis lucida variegata*.

No. 33. *Geranium Boule de Feu*; 2nd row, *Verbena Purple King*; 3rd row, *Geranium Christine*; 4th row, *Lobelia speciosa*; 5th row, *Geranium Queen's Favourite*.

No. 34. Centre, *Centaurea gymnocarpa*; 2nd row, *Coleus Verschaffeltii*; 3rd row, *Geranium Rose Rendatler*, with an edging of *Geranium Spread Eagle*.

No. 35. Centre, six good plants of *Arundo donax variegata*; next, a band 3 feet wide of *Dracena ferrea variegata*, with a foot margin next the grass of *Viola cornuta*.

To be successful with this bed and the following, it will be necessary to make proper preparations. The whole of the soil should be taken out, also 16 or 18 inches of the clay below the good soil. These beds should also be so situated that they may be easily drained. The bottom of the hole should then be filled up with brick rubbish, and this should come up 6 inches or so above the level of the clay; some chopped sods should then be laid over the brick rubbish to prevent the soil from trickling down amongst the drainage; the good soil should then be replaced, mixing in with it a good quantity of leaf soil, peat, and rough sand to keep the bed porous. If the soil become soddened and sour, farewell to the expected beauties of the sub-tropical garden bed. By preparing the beds as described above, and taking especial care to have them well drained, many of the magnificent tropical plants may easily be grown, especially in the south and west of England; and by taking extra care in preparing the plants previously to planting them out, selecting the warmest and most sheltered positions, much may be done with them even in the north. The wonderful results that have already crowned Mr. Gibson's labours at Battersea Park prove what can be done by energy, perseverance, and skill. What he has succeeded in doing during the past three years would have been thought an impossibility ten or even five years ago, and cannot be credited even now by many who have not had the advantage of seeing the sub-tropical garden at Battersea Park, which is worth travelling three or four hundred miles to see.

It is a pity on that account that the great gathering we have witnessed this week was not held later in the summer, so that many gardeners who have not enjoyed the privilege of seeing the sub-tropical department at Battersea Park might have done so on that occasion: for most assuredly they would there have learned one of the most useful lessons, not only as regards the out-door department, but would have greatly assisted them in the arrangements of their conservatory, plant-houses, &c. They will even now, thanks to the good judgment displayed by the Committee of Management for the Great International Exhibition in obtaining Mr. Gibson's valuable services for the arrangement of the ground on which the Exhibition is held, be able to form some idea of the wonders to be seen in the sub-tropical garden at a later period in the summer.

No. 36. Large bed. Centre, sixteen large plants of *Psephenia terminalis*; then a three-foot space covered with *Fuchsia Pillar of Gold*; then a double row of *Dracena congesta*, with a margin 1 foot wide next the grass of *Dietyis glomerata variegata*. If the space between the stems of the plants were covered with *Viola cornuta* this would set it off to great advantage.

No. 37. Large bed. Centre, *Caladium esculentum*; 2nd, *Canna bicolor*; 3rd row, *Canna rubra perfecta*, with an edging next the grass of *Centaurea candidissima*.

No. 38. Large bed. Centre, *Nicotiana wigandoides*; 2nd row, *Solanum macranthum*; 3rd row, *Gnaphalium lanatum*.

The following arrangements for ribbon-borders would look well either on grass or gravel. In planting a ribbon-border I

always, if possible, contrive to have the rows of *Verbenas* supported on each side by *Geraniums*, for the *Verbenas* can by this arrangement be so much more easily kept in their proper place.

No. 1. Back row, purple *Zelinda Dahlia*. This should occupy a space of 3 feet, and the plants should be so planted that they may quickly form a good thick row. Next plant 18 inches of *Calceolaria Aurea floribunda*, then a row of *Geranium Boule de Feu*; 4th row, *Verbena Purple King*; 5th row, *Geranium Flower of the Day*; 6th row, *Lobelia speciosa*; 7th row, *Geranium Golden Fleece*.

No. 2. Back row, *Dahlia Alba nana floribunda*; next row, *Ageratum mexicanum*; 3rd row, *Iresine Herbstitii*; 4th row, *Geranium Flower of the Day*, with the flowers left on; 5th row, *Viola cornuta*; 6th row, *Geranium Golden Fleece*; 7th row, *Verbena Velvet Cushion*.

No. 3. Back row, *Calceolaria amplexicaulis*—these plants should be planted pretty thickly together, and sticks placed to support them as soon as they are planted. If this is not attended to they will grow almost any way but the right way. 2nd row, *Amaranthus melancholicus ruber*; 3rd row, *Geranium Christine*; 4th row, *Verbena Purple King*; 5th row, *Geranium Cybister*; 6th row, *Verbena Cicely (pink)*; 7th row, *Lobelia speciosa*.

No. 4. Back row, *Calceolaria Sparkler*; 2nd row, *Geranium Flower of the Day*; 3rd row, *Verbena Claret Queen*; 4th row, *Geranium Bijou*; 5th row, *Verbena Purple King*; 6th row, *Geranium Little David*; 7th row, *Cerastium tomentosum*.

No. 5. Back row, *Geranium Stella*; 2nd row, *Calceolaria Gaines's Yellow*; 3rd row, *Heliotrope Florence Nightingale*; 5th row, *Geranium Bijou*; 6th row, *Iresine Herbstitii*, kept well pinched in; 7th row, *Arabis lucida variegata*.

No. 6. Back row, large plants of *Iresine Herbstitii*; 2nd row, *Geranium Christine*; 3rd row, *Verbena General Lee*; 4th row, *Geranium Flower of the Day*; 5th row, *Verbena Velvet Cushion*; 6th row, *Mangles's Variegated Geranium*; 7th row, *Lobelia speciosa*.

No. 7. Back row, *Geranium Boule de Feu*; 2nd row, *Verbena Le Grand Boule de Neige*; 3rd row, *Amaranthus melancholicus ruber*, kept pinched in pretty closely; 4th row, *Geranium Alma*; 5th row, *Verbena Princess Victoria*; 6th row, *Lobelia speciosa*; 7th row, *Geranium Queen's Favourite*.

No. 8. Back row, *Amaranthus melancholicus ruber*, large plants; 2nd row, *Calceolaria canariensis*; 3rd row, *Verbena Velvet Cushion*; 4th row, *Viola cornuta*; 5th row, *Geranium Golden Fleece*; 6th row, *Mimulus cupreus*; 7th row, *Cerastium Biebersteini*.—J. WILLS.

CULTURE OF VINES IN POTS.

(Continued from page 314.)

STOPPING AND REGULATING THE SHOOTS.—After the eyes have broken those at the lower part of the cane should be rubbed off closely, and all those along the cane from the bottom upwards for the required length to reach the rafter. I think it best to leave them until the eyes have broken, for if removed with a knife prior to breaking the wounds bleed, but if left until broken there is no danger of this taking place, and their being allowed to remain for a time calls into activity roots for their support. The removal of shoots or buds not wanted leaves more sap for those retained.

When the shoots are so far advanced that the fruit is visible at their points, a partial disbudding may take place, leaving, however, more than will be required for a crop, and if they show well every other bud or shoot may be rubbed off, and this will leave many shoots that ought not to be allowed to carry any fruit, but they will be useful for keeping up a good root-action, which is of primary importance. Take out the points of the shoots at the first leaf above the bunch, tying the shoots loosely to the wires, and being careful not to break the shoots. Laterals will issue from most of the joints, stop these at the first joint or leaf, as also the laterals proceeding from the joint at which the principal shoots have been stopped; as often as these laterals make a leaf pinch out their point. If fruit is shown at the joint to which the shoot is stopped in the first instance, as well as at the joint next below it, make choice of the best bunch as to size and form, cutting the other away.

BUNCHES.—Leave but one bunch to a shoot, one shoot from a bud, all others to be removed so as to leave the shoots 9 inches apart. From six to eight bunches are a good and almost too heavy crop; the bunches should therefore be re-

duced to that number immediately after the flowering is past, and the laterals below the bunches should be broken off close home, keeping those above the bunches closely stopped to one joint, or so soon as a leaf is made take out the point of the shoot; the tendrils to be pinched off close. Keep the shoots well tied down, and properly adjusted to the wires.

THINNING THE BUNCHES.—When the berries are the size of No. 4 shot commence thinning, first of all tying up the shoulders of the bunches. Thin out the smallest berries, and especially those with small wiry footstalks, remembering that as the berries are now small they must be left correspondingly wider apart than were they not thinned until larger. It is well also to bear in mind that the earlier thinning is commenced the less the nourishment afforded by the roots and leaves will be expended on those berries cut away, and the larger those left will be. It is well to go over the bunches twice, first giving a good thinning, and again in ten days or a fortnight going over them again, giving a final thinning, and if there is anything to be guarded against it is leaving too many berries. I find nothing so good for tying up the shoulders as yellow Japan flax, which from its fineness is scarcely visible, and it is of immense strength, even in very small shreds. In thinning avoid handling the berries, using a small round pointed stick about 7 inches long, and with this raise the shoulders and maintain the bunch steady in a proper position whilst the berries are being thinned out.

I stated in a former part of these notes that I would observe on the several descriptions of canes for fruiting at different seasons, but having gone through the whole routine of Vine culture it only remains for me to note the difference between Vines started in autumn and those after January, which consists in those started after that not requiring so high a temperature to commence with; 40° should be the maximum night temperature to begin with, increasing 5° fortnightly afterwards.

A correspondent finds a difficulty in "starting Vines in autumn to obtain strong canes for fruiting in January and February. They break well, but make such small straw-like canes as not to equal those raised in January from eyes, the others being strong one-year canes cut in to two eyes." I have experienced the same difficulty not only with Vines started in autumn, but with those raised from eyes—some always lag behind. Any having such will find stopping the Vines when they have grown a foot in length an excellent plan, cutting them immedately above a joint. A lateral will start from the joint to which the shoot was stopped, which, if allowed to grow, will make a leader, but of weak growth in comparison to that of the original. By the lateral is a bud, and to induce this to push the lateral by its side is to be pinched off closely, otherwise the principal eye would not push until next season. All the laterals below are to be pinched off closely, and then one or other of the principal eyes will certainly push. The shoot from a principal eye is to be preserved, and trained as a leader, which will usually be strong; if not, allow it to grow a foot and then stop it as before, and obtain a new leader from a principal eye by closely pinching in the laterals.—G. ABBEY.

(To be continued.)

SOWING VERBENA SEED.

I HAVE just read an article in your Number of April 17th on the raising of Verbenas from seed by Mr. Wills, and as his recommendations are entirely contrary to my own experience I write to say that I always find Verbena seed will vegetate, if properly treated, in about a fortnight, and will grow nearly as freely as Mustard. In proof of this, I have Mr. Perry's permission to show your correspondent some thousands of plants with the bloom-buds on them, all raised from seed sown in February last. The seed was not sown "2 inches" deep, as recommended by Mr. Wills, or I should not have been surprised if it had been from "seven weeks to two years" before the plants had made their appearance, or even if they had never seen daylight.—T. POINTON, *Gardener to C. J. Perry, Esq., The Cedars, Castle Bromwich, near Birmingham.*

DAFFODIL IN IRELAND.—On looking over the second volume of your "Wild Flowers of Great Britain," I find, under the head the "Common Daffodil," "Abundant in woods and moist meadows in the south of England. Rare in Scotland and Ireland." I beg to bear my testimony that it is most abundant in the county of Dublin, amongst old trees and in moist meadows,

and as far as I can learn it is almost as common in other parts of Ireland.—J. VERNON, *Clontarf.*

[Our authorities, Hooker and Arnott, speak of it as rare in Ireland, and Bentham says that it occurs "in Scotland and Ireland only where introduced."—EDS.]

HORTICULTURAL EXHIBITION AT THE ANTIPODES.

THE Horticultural Society of Canterbury, New Zealand, held its final Exhibition for the season on February 28th. The Exhibition, I am sorry to say, was not patronised by the public to the extent that it decidedly merited on this occasion. The display of flowers far exceeded the show of fruit and vegetables. This last Exhibition for the season certainly surpassed the previous two as regards the number, variety, and growth of the articles which were contributed. I send you a few notes I made on the occasion, which you must receive in the shape of gossip. I omit the long list of prizes awarded, and if you knew the intrinsic value of each award it would furnish you with a good hearty laugh.

I will begin with pot plants, which were shown in great profusion. The Fuchsias were really magnificent; some of the plants were 5 feet high and 5 feet through. They consisted of Sir Colin Campbell, Souvenir de Chiswick, Rose of Castille, Guiding Star, and some others; these formed the most attractive part of the show of flowers, and I may say there was not much else in this department to arrest the attention of those accustomed to good shows. I must say also that the Fuchsias were the finest I have seen in the province, and equal to any I ever saw at Chiswick years ago. I must specially notice some Gloxinias, Achimenes, Gesnera zebrina, and Clerodendron fragrans, as being without doubt the first time I have seen them exhibited here. They were beautifully in flower and well cultivated, and much admired by the visitors; many questions being asked about them as well. I missed from the plant-stages this year *Humea elegans* and *Perilla nankinensis*, which had a very graceful appearance mingled amongst the other plants. Stove plants seem to be creeping in to fill up their place. I am looking forward to see Orchids amongst us at no very distant period. Marble Balsams and Cockscombs were well represented on the table amongst other subjects, and are becoming very fashionable at our exhibitions. They put me in mind of those formerly exhibited at Chiswick about the year 1840 by Mr. Wm. Cock, which no doubt will be fresh in the memory of many of your readers. We have not been able to come up to him yet in growing Pelargoniums to such a large size, nor do I think we ever shall. Our Pelargoniums are grown so as to form much smaller and more compact plants. We are not far behind, however, in the growth of the Fuchsia.

Of native Ferns I noticed only one collection which, according to the schedule, should be twelve in number. Amongst them were *Lonarica elongata*, *L. nigra*, *L. discolor*, *Asplenium bulbiferum*, *Cyathea dealbata*, *Dicksonia squarrosa*, *Phymatodes Billiardieri*, *Cheilanthes tenuifolia*, *Leptopteris hymenophylloides*, and several others. They well deserved the small prize awarded, 7s. 6d. Seven-and-sixpence for a prize for twelve Ferns in pots! Why, it is ridiculous. I was sorry not to find in the collection *Asplenium Hookerianum*, for it is pretty plentiful in our bushes. I noticed at the Exhibition, in the shape of dried plants, a handsome species of *Gleichenia*, brought from our west coast gold field. I understand that plants of it are looking healthy with us as well. Your Fern-growers will be pleased to hear this. The taste for indigenous Ferns here is quite in the bud. We have an endless variety of them. I hope in course of time the taste for them will grow fully ripe amongst us, and that we shall see the bud fully expanded. We are not short of material to work on, I can assure you.

In finishing with pot plants I must not forget to mention double *Petunias*, which, mixed with the Fuchsias on the stages, had a very pleasing effect. We have them of all shades and colours, with flowers exactly like a double *Dahlia* or *Hollyhock*, and equal in size to a good *Rose*, and fragrant in scent. We can grow bedding-out plants here, and well too; neither are florist's flowers forgotten amongst us. We have progressed wonderfully in this way. Seeds of choice Verbenas, *Petunias*, &c., keep arriving every mail by post, thanks to our friends at home for sending them.

Of cut flowers, our *Dahlias* were not so fine as usual, owing

to bad weather; a good many were staved, nevertheless. Roses were inferior in quality, as is usual at this late season. What were shown were of the Bourbon section. I never recollect having seen so poor a show of the queen of flowers. Pansies were not so good as usual, though competition was being carried on in earnest with them. I expected to have seen a much better show of them and better culture. Some spike of very fine varieties of Gladioli attracted much notice. Some of the new varieties arrive every year when we receive our annual supply of Dutch bulbs. Marigolds, both French and African, were rather meagrely shown; one or two blooms of the former were only worth notice. One beautiful hand bouquet exhibited was, to my thinking, faultless. In bouquets, both table and hand, I cannot but record a decided and gratifying advance on former years. For the first time a collection of Helichrysiums were exhibited, and they were beautifully arranged.

Of fruit, some of the kinds of fruit exhibited were fine and large, but as to flavour and quality little was said by the Judges. I will endeavour to make up for this deficiency by stating what I think about the subjects of exhibition. I will begin with the Grapes. The bunches of Black Hamburgh were a decided improvement on other years, the bunches much larger, and of course heavier. They were only deficient in colour, having been cut too soon. We grow very good Grapes out of doors now in sheltered places, as well as Figs, which we could not grow seven year ago. Peaches were well represented by the Royal George and other sorts. Royal Georges being the largest, the Judges awarded the first prize to them, though they were deficient in colour. Other Peaches were there of much better colour, and, in my humble opinion, a ripe Peach looks nothing without a good rosy cheek. The temptation to help one's self was nearly irresistible, particularly to taste the Grapes and virgin honey in comb. Apples were a great deal better represented than Pears; some of the Apples were of very large size. For the first time three Water Melons were exhibited, grown in the open air, and of a good average size. I think I have now enumerated all the fruit worthy of notice.

From some cause or other the exhibition of fruit this year cannot be compared with exhibitions of other years. The interest felt in exhibiting fruit seems to be dying out and becoming neglected. Exhibitors here, as well as at home, have an eye to profit as well as fame. Fruit and vegetables are the "backbone" of our exhibitions here for the present, and if our Managing Committee would offer better prizes of real sterling worth they would soon find a great improvement in the productions. With better encouragement, better productions will follow no doubt, and more of them for competition.

The show of vegetables was highly creditable, and was an evidence of the suitability, soil, and climate of the province to produce, not only the essentials in common use, but likewise those that are regarded as delicacies of the table.

To finish with, I may mention that in addition to the prizes awarded by the Judges, a gold medal, manufactured of Canterbury gold, was exhibited during the day for inspection by one of the Managing Committee, and the medal is to be presented as a prize to the gardener who shall have obtained the greatest number of prizes at the three last Exhibitions of the Society. I consider the medal to be a very creditable specimen of colonial workmanship. My brother gardeners here, of old Adam's trade, have determined to celebrate the occasion of this medal being presented by an anniversary dinner.—WILLIAM SWAIN, *Tron-side Botanic Gardens, Canterbury, New Zealand.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

SEE that the directions given in former calendars have been attended to; where, from unavoidable causes, such has not been the case, lose no time in doing so now. Prepare trenches for early Celery, by throwing out the soil from 1 foot to 18 inches deep; and for the early crop, which is seldom allowed to stand till it attains full size, 2 feet between the trenches will be sufficient. Dig into the trench 6 inches of old hotbed dung, which for Celery is preferable to that which is rank and new; and as soon as the plants are ready plant them carefully, making a hole for the ball with a garden trowel, choosing a dull day for the operation, finishing with a good watering, and where practicable, shade for a time in bright weather. Little else can be added to last week's directions. Keep the hoe going. Prick-out all sorts of advancing seedlings, that they may get stocky and gain strength before their final planting.

Stir the surface of the soil wherever the late rains have caked it. Above all things watch for slugs, which are very numerous this season; sprinkle crops they are apt to attack with soot and lime mixed, and lay traps for them, such as cabbage leaves, slates, pieces of board, &c., and turn them over daily, when numbers will be found on the side that has been next the ground, and can be destroyed.

FRUIT GARDEN.

Strawberry plantations must now have a final hoeing till after the fruit is gathered, a long stirring of the surface of the soil amongst them would, when the fruit is set, cause the sand to adhere to the advancing fruit, and prove very injurious to them. Where spent hops can be procured cover the ground between the rows with them; they will keep the fruit clean, and they banish snails, especially in dry weather, for by adhering to their slimy skin, they make the insect uncomfortable, and, consequently, they change their quarters. Where spent hops cannot be procured, the best substitute is wheat straw. Attend to thinning the shoots of Raspberries and Apples on the walls, and lay in the Apricot wood where sufficiently advanced. Persevere in the destruction of insects on fruit trees as soon as they are perceived. Remove some of the water wood from the Currant bushes, and thin Raspberry suckers.

FLOWER GARDEN.

All annuals should be thinned out as soon as they are well above ground, for if left to grow too thickly they spoil one another, and never make half the display plants do that are allowed plenty of space, and which are grown strongly from the first. Attend to staking such of the herbaceous plants as require it before they get blown about and injured, and do not huddle the stems together. The early-flowering Tulips, Hyacinths, Turban Ranunculuses, &c., should not be left in the ground after the decay of the foliage, for if wet weather occurs they will be making fresh roots, which weaken them for next season. Attend to the propagation of the better varieties of Pentstemons, which are very useful plants. Also see to having a good stock of border Proteas and Ceanothus, which are valuable for cutting. Cuttings of these, if put in before the wood gets too hard, root as freely as Planks. The time for planting and bedding-out plants in the places where they are to form the great display of the flower garden is now come, and it cannot be too strongly urged upon those who have this work to do, that system in arranging the colour is absolutely essential to complete success. By those who have paid much attention to this part of the gardener's business, it must have been often noticed that different artists produce very different effects with the same plants, and this upon a careful examination will be found to arise more from the judicious arrangement of the colours than from any other circumstance. What can be more beautiful than some of the white Verbenas or the yellow Calceolarias? but place these two sorts together, and the pure white of the Verbenas is quite destroyed. Neither should colours be placed in violent contrast, because richness of effect is not produced by contrast, but by harmony. Thus, scarlets harmonise with purples or blues; these again with any orange-coloured flower; pink will harmonise most delicately with any flower of a pure white colour, and violet with yellows. In some cases, however, especially on gravelled terraces, contrasted colours are very desirable, and these are much more easily managed. Thus, the contrasting colour to scarlet is white, the contrast to purple is yellow, and the contrast of orange is blue, and so on of their different shades. Summer creepers should be grown to some size before being turned out, if early flowers are required. The colours of the flowers of the common Nasturtium are very beautiful, and if the leaves of the plants are thinned as they grow, interesting effects may be produced by the flowers. Plant in rich soil a good supply of Stocks and Asters for the autumn, and sow a succession of annuals for filling-up any vacancies which may occur, and likewise another sowing of Mignonette in pots for the rooms or for filling window-boxes. Look to young shoots of all old Fuchsia stocks, let them be thinned out to five or six. Attend diligently to standard Roses, constant disbudding is necessary at this period; also keep down suckers. Let every attention be paid to propagating reserve stock to fill gaps, and let that already rooted or the remains of store pots have kindly cultivation forthwith, in order to be ready to fill blanks. They should be kept in a shady border by themselves, that the proper keeping of the garden may be as little interfered with as possible, through the litter and confusion consequent on "turning out." Use every dispatch to bring this work to a finish; but if any

portion of the stock is not sufficiently prepared, allow it to remain under glass as much longer as may be necessary, and plant-out nothing but strong plants that have been carefully inured to the sun and air, for weakly ill-prepared stuff is so much at the mercy of the weather, that it is folly to depend upon its covering the ground in any reasonable time. Give sufficient water to settle the soil about the balls of the plants the first warm morning after planting, and give no more until the soil becomes dry, unless warm drying weather should set in, and then a gentle sprinkling every morning will greatly benefit the plants.

GREENHOUSE AND CONSERVATORY.

When the cold pits and frames have been cleared of the bedding stock, they will form excellent places during summer for the growth of many things for the autumn and winter decoration of the conservatory. Indeed, many of our most useful plants for this purpose will do better for the next three months in cold frames than in larger houses, where the state of the atmosphere is not so much at command, nor the plants so readily examined, as in these humble structures. Roses are, perhaps, more generally admired than any other class of plants, and bloom freely in the conservatory in autumn and early winter, if properly attended to at the right time. Young plants of the perpetual-flowering kinds, as Teas, Bourbons, Hybrid, and Damask Perpetuals, if placed in a cold frame and properly attended to with pot room, and liberally supplied with manure water, will soon form nice-sized specimens. But in order to secure their blooming freely in autumn and early winter, the flowers must be picked off as they make their appearance, and strong, stocky growth secured by giving abundance of air, exposing the plants to the night dews, and keeping the shoots stopped and tied out as may be required, and otherwise attending to the habits of the variety. Also, attend to the Japan Lilies, Chrysanthemums, scarlet Salvias, tree Carnations, and plants of that sort for autumn and early winter decoration. Give them plenty of pot room, good rich compost, a moist atmosphere, and plenty of space for the proper development of their branches and leaves. Epacrises, winter-blooming Heaths, and Cytisus, should likewise be cultivated in quantity, for few plants surpass them for winter decoration. The atmosphere of plant-houses can scarcely be kept too moist at this season, therefore sprinkle every available surface frequently, and syringe growing stock twice a-day during bright weather.

STOVE.

As regards stove plants and Orchids, thorough cleanliness, free ventilation, plenty of atmospheric moisture, and occasionally a slight shading in very bright sunshine, are at present the chief requisites. No means should be neglected to encourage a free growth in Orchids at this period, in order to get their pseudo-bulbs firm and well ripened betimes.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

FROM the 19th and onwards to the time of writing this there has been a bright sun, attended too frequently with dry parching winds, and less or more of frost in the morning. Protected some fresh-planted things with trays, and run the Dutch hoe through all crops sufficiently advanced to be seen, as alluded to last week.

FRUIT GARDEN.

Did the same with the hoe as respects *Strawberries* to prevent the ground cracking, which it threatened to do, and a loose surface is the great remedy for that evil; but unfortunately it also keeps the heat out, and, notwithstanding the bright sun, the earth is still cold at a small distance from the surface. Filled more frames with *Strawberries* showing bloom, lifting the nice young plants with large ever-so-many-shaped balls, which needed no disturbing, as they would have required if to be squeezed in pots. In such weather as this these plants will come in a fortnight before those out of doors. Arranged a row in pots in front of the orchard-house, where they will have plenty of light and air, and these will come in a week or ten days before those planted out in the frames. Before filling the frames we washed the back and the ends with a paint formed of three parts sulphur, and one part of lime and one of soot, the latter just to mellow the colour. The red spider is the great enemy of the *Strawberry* under glass, especially when the plants are placed up on high shelves. On the highest of our four shelves in the Peach-house we detected traces of the little enemy, and had the plants taken down at once

and the shelf removed. Put a coating of lime, sulphur, and soot on the pipes and on all the openings on the back wall; daubed them with a thick paint made of soft soap, sulphur, and a little water. We particularly daubed this close to the apex of the roof, and wherever there was a chance for the sun's rays to strike unobstructedly on it, as then strong fumes will be given off for a long time, and nothing will suffer from them if air is given early. The soft soap, besides giving off fumes unpleasant to all insects, causes the sulphur to stick pretty well, and so far bid defiance to the syringe. So painted the open places in the orchard-houses, and about 18 inches at the top of the wall in the vineries, as the only place where there was a chance of the sun beating on the wall. This simple application, and a little sulphur at times applied to the pipes, generally keep off the spider from Vines, without any syringing except merely to damp the floor and pathways.

Air-giving.—We believe that giving air early, or, where the coal heap will permit of it, keeping on a little air at the top of the house all night, would be found the great remedy against scorching, scalding, and even the attacks of the red spider. In one of these hot days with a fierce sun, a great enthusiast for air was astonished to find that at midday we had not more than 2 inches of air on at the top of the house, and nevertheless the house felt quite comfortable, and everything seemed to like the atmosphere at about 85°; but an inch was given early before the house rose to 70°, and the pipes were comparatively cool when the sun heat was strong. He told us he was sure he would have a foot of air at the top, and 6 inches at least in front, but, then, it was next to impossible to keep plants from being parched and shrivelled up. Well, the scarcity of water and the less labour in air-giving, as well as the teachings of Nature, which informed us that the greatest heat takes place during the day, led us first to lessen the quantity of air generally given to houses, so as to take full advantage of sun heat, the cheapest and the best of all modes of heating. Such a mode will scarcely answer with those amateurs who run to their houses at 9 or 10 A.M., and then after a bright sun pull down sashes and open doors, doing their best to shivel and dry up their plants after submitting them to a scalding, steaming process. Our advice to all such gardeners with small houses, who cannot get at their pets early enough in the morning, is never to shut up their houses entirely at top from the end of March to the end of October. Plants will rarely be scalded in such houses even with little air, as the heat of the sun rises gradually, and all heated vapours will freely escape. Nothing so much tends to make plants ready to receive the visits of all kinds of insects as placing them alternately in a vapour-bath, and then in a strong current of dry parching air.

A certain distance from the glass, say from 12 to 18 inches, according to the position, acts also as a means of safety. The foliage is much less liable to be scalded or scorched in such circumstances, and if the glass is at all large and good the plants will be in no danger of being drawn up weak. Keeping plants near the glass is a capital rule in dark shady houses, or where light only reaches them on one side, but it may be safely neglected when there is nothing above them to intercept the sun's rays. With free light above and on all sides, the plants may be kept sturdy and strong, though at a considerable distance from the glass. Cuttings may thus often be struck without the necessity of shading, and the diffusion of the rays before reaching them will save them from flagging, which they would be sure to do if unshaded and close to the glass in a bright sun.

Even in the case of early *Strawberries* there is less necessity for keeping the plants close to the glass, if they enjoy unobstructed light, and a current of air passing over them when they are in bloom, and at that time they are not subjected to a too high temperature. When the *Strawberry* sets most freely out of doors the average temperature, except in sunshine, will often range from 40° to 50°, and it is quite a mistake to suppose that the plants would set better if kept in a temperature of from 60° to 70° at night. When that is done, the vital energies of the plants are unduly exhausted, unless, indeed, when the custom is adopted of keeping down the temperature during the day, with large admissions of air. For instance: very fine Grapes have been produced by keeping the night or day temperature within 5° or 10° of each other, but it is a much cheaper plan to imitate Nature in this respect, and allow a considerable fluctuation of the temperature between a cold night and a bright day, and thus get the sun to help us instead of always resorting to the coal heap.

Temperature.—One other thing we must here allude to. The

cool temperature at night, and the high temperature during the day from the effects of sun, are the best means of all others for keeping insects at bay. Keep a high temperature at night to unduly expand the tissues, when there is no sun to concentrate strength, and the weakness thus secured just gives every encouragement to insects to commence their ravages. In destroying them, we have great faith in heat suddenly applied, when as a liquid it seals the insects and yet does no harm to the plant; but for keeping them off commend us to letting the plants have rest, instead of excitement in darkness.

And then again, on the principle of sudden fluctuations, plants are safer every way when a fair distance from the glass than when they are exposed close to it. We should be afraid to tell what a gentleman told us his tobacco and Gishurst, &c., cost him in a twelvemonth, and we recollect a great gardener telling us that when last he went through that gentleman's houses he had a good sprinkling of menly bug on his clothes. We believe that after a cleaning process had been gone through the keeping clean would have partly depended on burning less fuel. Even in the tropics the heat is not always at fever heat at night, and there is not always a parching draught of air during the day.

Small Plant-houses.—There are two things that prevent many an enthusiast from having one of these plant-houses in his little garden or attached to his residence. The first is, he hears from all great gardeners about the superiority of hot water, but he dreads the bill of a hot-water man, and he cannot get into the simplicities enough to have faith in a stove or a small flue. The second drawback affects the giving of air. It is more than a mystery, it becomes a puzzle and a drawback. He knows that if he opens the door a good deal of air will at once enter—that is, that there will be immediately an attempt at equilibrium between the atmosphere without and the atmosphere within; but then the opening of the door would be too much in coldish weather for his small house of, say, 12 to 18 feet long and 8 to 12 feet wide. He can easily have a sash or two, or large-framed squares, made to open in front; but then he knows that a fixed roof is a great point of economy, and he dreads the expense and the bother of having moveable sashes or ventilators at the apex. Well, for all such small plant-houses, although as has been seen, we are advocates for air-piving at the apex, yet from 12 to 15 inches of an opening at each end of such apex will prevent all mischief, provided that in extra hot weather more air is given by the ventilator in front or by the door in hot weather. If these end ventilators stand open night and day from April to the end of October, the labours of the amateur will be vastly diminished.

For the thousands of our readers, many of whom are anxious to have a house, and are deterred by this question of air and its generally supposed intricate minutiae, we wish for their encouragement broadly to proclaim that, provided air is given early, much less than is generally supposed will do—and that if the temperature inside during the day will fluctuate backwards and forwards, according as the sun enters or emerges from a cloud, the plants will do better than when treated on a more unnatural, though perhaps more attentive system. We have ourselves done it, and seen others lessen and enlarge the air-openings of houses some six or seven times in an hour—a good thing for securing attention as well as wearing shoe leather, but really doing no great amount of good to the plants so treated.

ORNAMENTAL DEPARTMENT.

Kept potting Fuchsias, Geraniums, Begonias. Brought Camellias into vineries, the plants quite done blooming. Potted Ferns, and Selaginellas. Brought Azaleas done blooming into a closer moister atmosphere, and this is just one of those cases in which we little folk have to think and scheme more than many of our great gardeners, who have a place and a house for everything; the man who has a flowering and a growing house for Azaleas can easily keep the one cool, and the other in the humidity and heat of the tropics; but the difficulty with the man of one house is to give flowering, and growing, and resting plants the right treatment they require under the same roof; and what is not quite agreeable is, many employers, who should know better, expect results in their small places which can only be fully obtained when there is a place for everything according to its requirements. Our work, however, has chiefly been in rolling, mowing, cleaning up, and, as the nights are still so cold, preparing the ground by digging and turning in sunbeams, for getting the flower-beds into a suitable state for the reception of the plants that are now chiefly growing in earth-pits and trenches with less or more of protection.

There are two things of importance which we have lately learned, and which we cannot well keep back for the discoverers to speak about. The first is the efficacy of a common fishing net spread over the glass for preventing turning over of fine-foliaged plants, and giving a better colour than a dense shade; and the second is the plan of striking cuttings of *Centaurea combidissima*, &c., on the cool system, as practised by ourselves and others with *Calceolarias* in the autumn, of which Mr. Robson could tell us something interesting.—R. F.

COVENT GARDEN MARKET.—MAY 23.

A good supply of both foreign and home-grown produce, and last week's quotations are generally maintained. Some English Green Peas are now coming in, and will materially influence the market for those of French growth in another week. There have been heavy arrivals of Potatoes from the west of England and the Channel Islands, and of good quality.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Holloway.—*General Catalogue of Plants.*
F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Select Bedding Plants, &c.*

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

INSECTS (*B. Ball.*)—We examined with a powerful magnifier the soil you sent, but were unable to discover any insects. If there are any which hide in the soil, sprinkle guano over the surface.

EXHIBITING-STAND FOR ROSES (*W. H. M.*)—Rose-stands should be 1 foot 6 inches broad, 6 inches high at the back, and 4 inches in front; the length of box will vary according to the number of blooms. The holes should be about 6 inches apart, and a tin tube in each to hold water.

GERANIUM IN WINDOW (*W. H. B.*)—1. We do not recommend guano to be mixed with the soil, but you may use it advantageously by dissolving an ounce in a gallon of water, and with this water the plants at every alternate watering. 2. The plants should have a shift at once into pots 7 or 8 inches in diameter, and not less than 6 inches. 3. Plants thrive best in common pots.

DEVONSHIRE ROSE FLOWERS NOT OPENING (*T. T.*)—We think the atmosphere of your greenhouse has been kept too close and moist, and the temperature too low. To open well, a temperature of 50° to 55° is requisite, and a rather dry atmosphere.

RED SPIDER (*Under Gardener*).—See what Mr. Fish says to-day in "Doings of Last Week."

ERRATUM.—At page 576, second column, No. 21, "*Helianthus*" should be "*Melianthus*."

AZALEAS IN ROOM (M. C.).—Providing the room is light, and the plants kept near the glass, you may keep Azaleas there in autumn and winter; but they will not do so well as if kept in a greenhouse; and they will need placing in a warm and moist house to make growth after flowering, to secure new growth, and the setting of the bloom-buds. Though you can keep them in a room, it is not desirable to do so longer than can be helped. A few days whilst in bloom do not do them any great harm; but, as a rule, it should be restricted to that.

EUCCHARIS AMAZONICA NOT BLOOMING (Idem).—Your plant does not bloom because the annual growth is not well ripened. After the growth is made, expose fully to light and air, give no more water than sufficient to prevent the foliage flagging, and it will bloom in due season. Get a good growth, and well ripen it off.

GEBANUM LOND OF THE ISLES BLOOM (Idem).—The flowers of this have a tendency to be crumpled and not to open flat, it being aggravated by not ventilating so as to avoid cold currents, and the absence of a slight shade will cause it, as will the plants being attacked by aphid.

WALL FOR PEACH TREE (A Subscriber, Linn).—Your wall (8 feet), is sufficiently high, and the trees should be pruned level with the top of the wall. You may also raise the wall as you propose, but it is quite unnecessary, unless you have some other object in view.

SEEDLING SCARLET PELARGONIUMS (Thomas Sampson).—Your seedling Pelargoniums appear to be of the right sort, and although similar to some already before the public, they are of great merit. The deep

rose flower of the Christine section is very good, and the brilliant scarlet Nosegay a very promising flower. There is great substance and smoothness of petal in all the seedlings, but to arrive at their respective merits they must be compared with others. Seedling Pelargoniums are innumerable. Could you not name them? Send some plants for the opinion of the Floral Committee, South Kensington; you would then ascertain their value and merits.

GLASS (Spalding).—Hartley's rough plate glass is the kind you allude to, probably. Any wholesale dealer in glass who advertises in our columns can supply you. You had better write to one or two for prices.

SCALE (S. A.).—The scale on your Plum tree may be a new species of Coccus, but more probably C. persica.

APPLYING GUANO WATER IN DRY WEATHER (Agnes).—There is not the least objection to using guano water, 2 ozs. to the gallon of water, to Strawberries and Roses during dry weather; but at such times, and such only, can manure water be of benefit, for in moist weather water is not needed, and any manure applied then are best given on the surface so that the rains may wash it in. Guano water will injure the blossoms if it touches them. It should be applied between the rows of the Strawberries, a good watering being more efficacious than many dribbles.

NAMES OF PLANTS (H. K.).—*Caladium Belleyneii*. (M. E. M.)—1, *Blechnum occidentale*; 2, *Scolopendrium vulgare*, var. *crisatum*; 3, *Asplenium bifidum*. (F. Angel.)—1, *Aster fruticosus*; 2, *Cistus ladaniferus*; 3, *Lisianthus*; 4, *Cantua baxifolia*; 5, *Solanum capsicastrum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 26th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. ab.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WOODBRIDGE EXHIBITION OF POULTRY.

This Show has now been most successfully carried on for the last five years, and year by year its improved character has reflected much credit on its management. The whole of the surrounding neighbourhood is most rural and pleasant; and the spring-tide of the year, when the leafage shows in such splendid contrast to the blooms of the Horse Chestnuts, now at their prime, is just the season of all others to attract the visits of those persons whose lot it may be to spend their days within the limits of populous towns. To such individuals the contrast of a "country out" is most covetable, and the attractions of ringing of the church bells, and the performances of the Third Volunteer Band, together with a local drum and fife band, each and all vied to draw together as large a company as possible. Again, the suburbs of Woodbridge are notorious for the abundance of its Nightingales—so much so, that it is not by any means an uncommon occurrence to hear three or four of these birds singing at the same time on the show grounds, and not a few visitors availed themselves of this opportunity of listening to these charming songsters. In the burial ground belonging to the Seckford Almshouses, not far distant, the Nightingales may also be heard to great advantage, both by night and day, singing as it were a requiem over the bodies of those aged participators in this very excellent charity who are already called to their "long home." In proof of the salubrity of this situation, by referring to the numerous tombstones we find the shortest-lived had weathered through sixty-four summers, and that the majority had closely approximated to one hundred.

By the very kind permission of Colonel Long, the Abbey Grounds were thrown open, as heretofore, for the purposes of the Poultry Show. They are singularly well adapted for such a meeting, and two large tents erected on the lawn provided thoroughly against every possible exigence of weather that might have arisen, but most fortunately the day was very propitious. Mr. Cooke, of Colechester, provided the pens, than which none can be better suited for the purposes of a show. The greatest cleanliness was observed throughout, and the popular expression of gratification was general among all comers.

The Woodbridge Show was strong in the Game classes, Mr. Matthews, the well-known Game breeder of Stowmarket, exhibiting a most splendid collection, and as will be seen by consulting the prize list appended, taking no inconsiderable portion of the prizes allotted to these classes, and in the first class all three. A most capital Duck-wing hen shown with one toe altogether deficient, from some previous mishap or other, lost this gentleman, we are told, still another side-board trophy. Mr. James Fletcher, of Manchester, showed some excellent Duckwings, and also obtained a plate premium. The *Dorking* class contained a most worthy muster of good birds, but from their

owner's mismanagement great numbers of them were sadly diseased in the feet and toes. It cannot be too strongly impressed on Dorking breeders, that the perches used as roosting-places for these weighty birds should never be above 2 feet from the ground. If placed higher, braised toes and ulcerated feet are the inevitable result. Many very good individual birds of this breed were shown in the "Selling Class," but not matched in feather properly for exhibition. In *Cochins*, the Partridge-coloured were mostly very good, whilst many pens of good Buifs were also shown. The three prize pens of Black *Spanish* were capital birds, and the two principal ones were exceedingly well shown in *Beahms*, the dark-feathered variety were worthy of especial mention, and obtained the extra cup for Brahmas, "dark or light-coloured." The latter variety were deficient in substance. The Golden-spangled *Hamburghs* were remarkably good, and the Silver-spangled but little inferior. In the last-named class we regret to find Mr. A. K. Wood, of Barnside, Kendal, lost a most excellent hen. She was reported as being dead by the guard in charge of the train on the railway, on her reaching the Bishopsgate Station, and certainly appeared on her arrival at Woodbridge to have been dead a considerable time. It is a serious loss to the owner, as it will be an unusually difficult task to replace her. She was without any delay repacked in a small basket and sent back to the owner; the cock, however, remained a solitary occupant of the pen allotted to them, and was a remarkably good specimen. The Silver-pencilled *Hamburghs* were not at all a first-rate class, but the class for "Any other variety of fowls," was capital. La Flèche, Houdans, and Silver-spangled *Polands* were the successful breeds; but *Rumpless*, *White Silks*, and a very singular pen of *Cuckoo-coloured Rumpless*, are mentioned in the prize list. We cannot speak so highly of the *Game Bantam* class as of single *Game Bantam* cocks, the excellence being limited almost exclusively to the winners only. In "Any other variety Bantam class," *Birchen Greys* stood first, and some good *Japanese* were the recipients of the second prize.

The *Rouen* and *Aylesbury Ducks* were good, but the competition was very limited. The same may be said respecting both the *Geese* and *Turkeys*.

The *Pigeon* premiums being confined to a first and second prize only, drew out but few competitors, though many broods were available. The first was taken by *Black Carriers*, and the second by *Black Magpies*.

Very unfortunately from some mismanagement on the part of the railway authorities, a very considerable number of pens were delayed until the morning following the arbitrations, and were of necessity entirely thrown out of all chances of prizetaking. In fact, some of the baskets of fowls were actually just come to the Woodbridge Railway Station, when the Judge was leaving the next morning. There appeared to be above a dozen in number by this train, independently of even a larger quantity, that were too late for competition the night before, though the awards had been purposely delayed till evening. It certainly appears at first sight somewhat inexplicable how it should

occur, that birds sent off altogether should arrive in three different consignments—a feature that can admit of no other solution than vigilance on the part of the railway officials themselves.

Certain it is, no committee could be more anxious to oblige every one than that at Woodbridge, and all that the most scrupulous care and attention could do was done in every case, so soon as the birds came into their hands. Of course, to owners it is a matter of considerable annoyance, without referring at all to the wasted outlay in carriage and the expense of entrance money. The transit of show poultry ought to be always immediate, to prevent these mishaps.

GAME (Black-red-sted and other Reds).—First and Cup, and Second and Third, S. Matthew, Stowmarket (Brown Reds); High R. Commanded, J. Fletcher, Stow-cough, near Manchester (Brown Reds); E. Pettitt, Colchester (Brown Reds).

GAME (White and Piles, Blacks and Brass-winged).—Prize, S. Matthew (Pile).

GAME (Duckwings and other Greys and Ribbons).—First and Cup, J. Fletcher (Duckwings).—Second, S. Matthew (Duckwings).—Third, J. Goodwin, Holesby (Duckwings).

DOERING (Coloured or White).—First and Second, H. Lingwood, Needham Market (Coloured).—Third, E. Parlett, Chelmsford (Coloured).—Highly Commended, Rev. T. Palmer, Trinity St. Martin (Coloured); J. Frost, Wickham Market (Coloured); D. C. Campbell, M.D., Brentwood (Coloured).—Commended, W. H. Walker, Shenfield, Brentwood (Coloured); T. Tatham, Kites the top, Northampton.

COCHIN-CHINA (Fairfeather).—Cup, First and Second, J. Stephens, Walsall. Third, W. F. Josling, Chelmsford.

COCHIN-CHINA (Any variety).—First, T. Tobham, Bury. Second, Rev. C. Spencer, Attleborough, Bury. Third, H. Linwood (Bury). Highly Commended, Rev. C. Gilbert, Stumpshaw Hill, Norwich. Commended, S. Felgate, High White, G. Manning, Springfield (Bury); F. W. Kust, Hastings (Bury); Rev. C. Spencer (Bury).

SPANISH.—First and Second, R. Wright, B. Roway Road, London. Third, J. S. Johns.

BRAMA POUTRA (Dark).—Cup, J. H. Piddles, Bridge End, Todmorden. Second, J. Wright, Wood ridge. Highly Commended, E. Smeerman, Chelmsford; J. Wright, J. K. Fowler, Aylesbury.

BRAMA POUTRA (Light).—First and Second, J. Pares, Postford House, Guildford.

HAMBURGH (Golden-spangled).—First, A. K. Wood, Berriside, Kendal. Second, E. Garrett, Sump Bridge. Highly Commended, J. Wright, Commended, Rev. T. L. Fellowes, Boughton Rectory, Acle, Norfolk; I. F. Leversidge, Newark.

HAMBURGH (Golden pencilled).—First, C. Havers, Ingatstone, Essex. Second, Rev. T. L. Fellowes. Highly Commended, Mrs. Burrell, Ipswich.

HAMBURGH (Silver-spangled).—First, A. Woods. Second, J. Wright. **HAMBURGH** (Silver-plumbed).—First, T. J. Saltmarsh, Chelmsford. Second, Rev. T. L. Fellowes.

ANY VARIETY.—First and Second, Rev. C. Gilbert (Houdans and La Fleche). Third, J. Binton, Binton, near Bath (Silver Polands). Highly Commended, Mrs. Burrell (Silver-spangled Polish and Silkies); E. Pizeon, Lymstone, near Exeter (La Fleche); W. A. Lathbridge, Bottisham, Cambridge (Crève Coeur). Commended, T. Bryant, Chediston, Halesworth (Dimples); J. Read, Lin Road, Magna (Rumpless); W. A. Lathbridge (La Fleche).

BANTAMS (General).—First, G. Manning. Second, R. E. Postens, Dredwood. Third, H. Sumball, Gedney, near Wisbech.

BANTAMS (Any variety).—First, Mrs. Pattison, Maldon, Essex (Duckwing). Second, T. Pigeon (Japanese). Highly Commended, G. Manning (Golden Schright); Mrs. Burrell (Rumpless); Mrs. Saltmarsh, Chelmsford (Gold-bred Schright).

SELLING CLASS.—First and Second, F. A. Kent, Kesgrave, Woodbridge, Suffolk (Coloured Dorkings). Third, D. C. Campbell, M.D. (Coloured Dorkings). Highly Commended, J. Frost, Wickham Market (Coloured Dorkings). Commended, R. Goodwin, Wood ridge (Game Duckwing).

GAME COCK.—First, S. Matthew. Second, E. Pettitt. Highly Commended, W. G. Murcl, Wickham Market.

BANTAM COCK.—First, Rev. G. Raynor, Kelvedon Hatch, Brentwood. Second, Mrs. Smeerman. Highly Commended, E. Pizeon. Commended, R. Garrett.

DUCKS (White Aylesbury).—First and Second, J. K. Fowler. Highly Commended, Rev. M. E. Bernard, Margravetung, Ingatstone.

DUCKS (Rouen).—First, Rev. T. L. Fellowes. Second, J. K. Fowler.

GEES.—Prize, C. Cypou, Framlingham.

TURKEYS.—First, C. Cypou (Black Norfolk). Second, R. Garrett.

PIGEONS (Any variety).—First, J. Pass, Ipswich (Carriers). Second, E. Pigeon (Magpies). Commended, R. Goodwin (Carriers).

JUDGE.—Edward Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham.

SHEFFIELD EXHIBITION OF POULTRY AND PIGEONS.

It cannot be disputed that the Show just held at Sheffield has proved by far the best that has ever yet taken place in that locality. It appears that the Sheffield Shows have been hitherto not so pecuniarily successful as was expected, but the Committee of this year determined to have no stone thrown that might tend to increase its popularity and consequent success; therefore, they have added an exhibition of Dogs, a feature that evidently possesses much attraction.

This leads to a passing remark that may prove useful to our general railway companies, if they listen to the suggestion, and may prevent a great amount of vexation and loss to both themselves as public companies, and also to parties who feel the deepest interest in the objects they exhibit. We allude to the very reprehensible practice of packing dogs in the same van with poultry of any kind during transit to shows. Every one must admit that dogs as well as poultry share in the general excitement of railway travelling, and, consequently, it cannot be a

matter of astonishment if, when birds are noisily excitable, they should receive injury from dogs closely confined with them—dogs, too, that perhaps have hitherto been altogether unaccustomed to such poultry clamour. All the particulars of these cases we have not been favoured with, therefore can only give the results so far as they have come to our knowledge. Mr. Yardley's well-known pen of Yellow Dragon Pigeons, the prize-winners at many and many a show, were not only killed but almost entirely eaten by a dog on their journey to the Show, their assailant having ripped up his own bait and their's also to effect his purpose. "Romaine," a very celebrated bull dog, considered by judges the best bull dog of the day, and for which the owner gave £150 only a very few months back, was found dead, apparently from suffocation; and a very valuable batch of the same excellent breed proved on its arrival so far gone that it was only recovered after great difficulty, coupled with the most anxious attention for several hours. Surely for the future, railway companies will see the absolute necessity of providing separate vans for dogs; and any careful observer at the Sheffield Show might easily perceive by the broken plumage of various pens, how continuous must have been the alarm of the birds from the close proximity of their ferocious assailants when travelling. But enough has been said on a subject by no means pleasurable to dilate upon.

The Show was held on the Cricket Ground, about two miles or a little better from the centre of the town—a lovely spot for the purpose, but to our mind one a little too far out for visitors. The weather was in every sense "Queen's weather," and the public seemed thoroughly to enjoy the treat provided.

It is only very rarely so capital a class of Spanish fowls meets the eye of an amateur, and Mr. B. Eldon may well be proud of his success; for in addition to first prize in the Spanish class, his excellent pen obtained the extra prize of a case of fifty-three pieces of the best cutlery, liberally presented by one of the Committee, Mr. Brown, to insure a good entry. It was quite evident that this prize was intrinsically worth far more than it represented on the prize schedule—a feature most creditable to the donor.

The Grey Dorking was mostly scaly out of feather, but there was an abundance of good birds. Some White Dorkings were also well shown.

Mr. Bierley's Game cocks proved one of the great attractions of the Show, though shown among a whole host of by no means unworthy rivals. Most of the Game were exceedingly good, but several pens lost position from having the neck-hackles and saddle-feathers "trammed," a practice that is not required by a good bird, and by no means improves an indifferent one. It would be well if the habit was abandoned altogether, though, we are sorry to add, it has now become far too general. Though there was a numerous entry of Game Bantams, the generality of them were not first-rate.

The Spangled Hamburgs were all that could be expected, but the Pencilled ones were not worthy of remark.

The Polish fowls were an exhibition in themselves. The Brahmans, though including a numerous entry, were not such as might have been expected.

The Cochin classes contained many most excellent specimens, but the end of May is unfavourable to their being shown in first-rate condition.

The entry of the "Single Game Hens" was capital, but, perhaps, no task could have been assigned to the Judges more critical than the awarding prizes to Game hens, many of which were inveterately "broody."

The Duck classes for Rouens and Aylesburys were really deficient, but an unusually good extra Duck class made ample compensation. In this, Mandarins, Carolinas, Grey Calls, and some other varieties were shown in the highest possible perfection of health and plumage.

The extra class for "Any variety of poultry," contained Houdans, La Fleche, Guelderlands, Indian Game, &c.

There were not shown in the Bantam classes some capital Japanese.

The "Selling Classes," for both Pigeons and poultry, were an entire success, the entries being most abundant, and sales were plentiful. These classes are, of late, generally well filled, and frequently, too, with birds superior to those shown for the general prizes.

The show of Pigeons was throughout, without question, remarkably good; so much so, as not only to elicit the highest approval of the Judges, Messrs. Hewitt and Tebb, but also the warmest admiration of the many Pigeon amateurs present. In brief, the Short-faced Tumblers were perfection itself, as were not a few of the Posters, Owls, and Toy varieties. The extra prize for the best collection of Pigeons was obtained by Mr. Yardley, of Birmingham, with a very meritorious and extensive selection.

All the arrangements were good; the Committee, themselves being amateurs, looked personally to every detail, and the result necessarily was, everything was scrupulously clean and in order. Under the present management we sincerely hope the Sheffield Committee may be able to secure for their town the high position a poultry show ought to maintain in the northern counties, where so many of our leading poultry breeders are located.

We published the list of prizetakers last week.

CIRENCESTER POULTRY SHOW.—Since my few lines on this Show last week, the schedule has undergone some change. A

Polish class has been added, and the second prizes increased in all the classes to 15s., the third prize being withdrawn except in the selling class, the restricted price in this class being fixed at £2. The Bantam classes and the Dutch classes still have second prize 10s. In lieu of a silver cup for the best single-cock in the sweepstake classes, the best bird in each class will receive an additional prize of 7s. 6d. This is a good alteration. The prizes are most liberal for the entry—viz., 3s., and we southerners must trust that the Show will prove successful.—Y. B. A. Z.

NEW BOOK.

The Apiary: or Bees, Their Lives, and Bee-Culture. By ALFRED NEIGHBOUR. Second edition. London: Kent & Co., and Geo. Neighbour & Sons.

MR. NEIGHBOUR'S book, the first edition of which was noticed by us in February 1855, now makes its appearance in a new guise, being reduced from demy 8vo. to crown 8vo., whilst the number of its pages is increased from 134 to 274, with but a slight increase in price. In addition to a description of the various hives and apiarian apparatus sold by the well-known firm of which the author is a member, it contains a considerable amount of generally accurate information compiled from the best authorities, Mr. Woodbury's contributions to our pages being in particular heavily drawn upon.

A new feature in this edition is a couple of steel plates illustrative of the anatomy of the bee, engraved by Mr. E. W. Robinson with his customary ability; embracing also coloured delineations of the three sexes of the Ligurian or Italian variety of honey bee. Of these illustrations that of the queen is the best, the worker not doing justice to the elegant and graceful form of the original; whilst the drone is simply a faded cabinet specimen which has shrunk to the length of the worker.

Mr. Neighbour possesses a very great advantage over a mere compiler in that he is himself a practical bee-keeper, and divers anecdotes of his experience are related by him in a light and amusing manner. For this reason, also, the information conveyed in his pages is, as we have already stated, very generally correct, although he may occasionally be found tripping. For instance; it is stated in page 17 that the eggs of drones and queens "are hatched in warm summer weather, a higher temperature being necessary;" whereas a queen has been known to be hatched at Christmas, and natural drones frequently make their appearance in March, whilst in stocks possessed of drone-breeding queens they come to perfection much earlier. In page 22 we are told that "the cause of a swarm leaving the stock hive is that the population has grown too large for it," an idea which has frequently been disproved. In the new chapter on the anatomy of the bee we are assured that it is with the foremost pair of its six legs that "the bee unloads the little pellets from the baskets on her thighs;" we can only conclude, therefore, that the writer has never seen a worker bee perform this everyday and simple action. In page 169 it is stated that for the successful formation of an artificial swarm it is "necessary that the hive contain drones;" another mistake, as the presence of drones in neighbouring hives is sufficient. We are also told that when bees are likely to incommode workmen or others, instead of confining them, "it is better to move the hive a few paces." We certainly should not be disposed to envy either the workmen or the bees where such an expedient has been resorted to.

Mr. Neighbour copies the Rev. Mr. Tristram's erroneous statement, that the Italian variety of honey bee is indigenous in Palestine, and remarks thereupon—"Does not evidence such as this point to the conclusion, that the bees which Samson found in the carcass of the lion were *Ligurians*? and may we not further speculate that the ribs of the carcass constituted the first *lar-hive*?" Whatever may be thought of this latter rather fanciful speculation, it is certain that Mr. Tristram's evidence is incorrect, there being no doubt whatever that, as stated by Mr. Woodbury in our pages a few weeks ago, the Syrian honey bee is entirely distinct from that of Italy.

The engraving copied from Klein's work and representing a royal cell on the edge of a comb protected by a wire pipe-cover, embodies an idea which, like others of our German friends, is more ingenious than practical. We were ourselves somewhat taken with it at the time, but having submitted it to the test of experiment in queen-rearing operations, we soon discovered it to be of no value whatever.

We cannot but think that a little more care might have been advantageously bestowed upon the index, which is frequently incorrect. A good index is, beyond question, a most valuable adjunct to a work of this kind; but one which so often refers the inquirer to a wrong instead of to the right page, is likely to prove a sore trial both of his temper and his patience.

Notwithstanding this drawback, Mr. Neighbour may be considered as having performed his task in a creditable manner, and substantially to have attained the end at which he professes to have aimed—viz., that of producing a "handy book which should contain full and detailed replies sufficient to meet all ordinary inquiries."

SPARROWS EATING LIVE BEES.

I SEE by a letter in your last week's Journal that we bee-keepers need not fear sparrows eating our bees, but only tamely perpetrating that enormity. Up to last week I was myself of that opinion, never having seen sparrows attack a single episode nor would I have believed any one who had told me the contrary, thinking they must have made a mistake. However, on Sunday last, in the middle of the day, I noticed one of these birds jumping up at the hives, and immediately flying a few yards off, and there humming a bee round in its beak, and then starting off to the nest with the wings and legs of the insect left behind. In a few moments back it came again, renewing the operation, and this time accompanied by its mate, both of them flying away each with a killed bee. On further watching I not only saw this couple, but two other couples doing the same thing, each flying to its own nest and feeding their young. So actively were they doing this, that there was always one dead at least on the ground in front of my hives, and sometimes three. Hitherto I have rather encouraged these birds building round my house and stables, and at that time there were at least fifteen or more with young and eggs in various stages of progression. I immediately ordered their destruction, and the next morning my gardener told me he had found more than fifteen young birds, which, with six destroyed by me, made twenty-one young sparrows offered up to the manes of departed bees.

I have kept bees for more than twenty-five years, yet I had never before noticed such an occurrence; and I believe it to be an exceptional thing, owing to the dry, harsh, easterly winds and cold nights preventing the development of insect life, upon which almost entirely the young sparrows are fed. Driven hard to find subsistence for hungry mouths, the parents had recourse to living bees, and dearly they have paid for their tenacity. Whether this has been the cause or not I do not know, but most of my hives are very backward and no honey collected, whereas this time last year they were making honey fast.—A BUCKINGHAM.

P.S.—I have this day (23rd) had my first swarm; very large.

DO SWARMS EVER ISSUE BEFORE DRONES MAKE THEIR APPEARANCE?

MY reason for asking is, that on the 17th inst. I opened my Ligurian hive, which I received from Mr. Woodbury in October last, and I could not find the queen, but I found five sealed royal cells. There were not the least signs of drones, drone brood, or drone eggs, and the population seemed to have decreased; and there appeared to be no breeding going on, there being no young brood in the hive. I opened the same hive again on the 18th inst., and found the royal cells being torn open, and the young queens, two of which were killed, making their appearance. I captured one, and placed her in a nucleus-box with a comb of bees out of the parent hive, and gave her a broodcomb out of a black stock. I also placed the comb containing the only royal cell that was not torn open into another nucleus-box, after having brushed the bees back into the hive, and added to it a black broodcomb well covered with bees. I could only find one more queen, which I left in the parent hive. Is it possible that the mother of the hive may have led off a swarm? or what do you think has become of her? They have never shown the least signs of swarming. There is not a single drone, either Italian or English, to be seen in my apiary, which consists of one Ligurian stock and five English stocks, all of which are in Woodbury hives, and the two nuclei before mentioned. I have been very particular to discourage drone-breeding among my black bees, by cutting out all the drone-

comb as fast as it is built, so that my queens may become impregnated only by Ligurian drones; and now I have no drones at all. My English bees are breeding fast, but the Italians seem to be at a stand-still. If my Ligurian mother has gone off with a swarm, or met with her death, may I expect to keep my Ligurians pure under the present circumstances? or, in other words, will the young queens to which I have alluded commence and continue drone-breeding until they become impregnated by their own progeny? or would it be better for me to purchase another swarm or stock containing a good supply of drones?—A. R., Birmingham.

Swarms rarely, if ever, issue before the appearance of drones; but in your case the question does not arise, there appearing, unfortunately, no doubt whatever that the Italian queen is actually defunct, and the stock must, therefore, continue to retrograde until the young queen becomes capable of recruiting the waning population. Notwithstanding the paucity of drones in your own apiary, we believe your young queens will succeed in their wedding flights. They cannot under the circumstances fail of being hybridised, as it is certain that they cannot be fertilised by their own male progeny. We do not see that you can do better than obtain another stock with which, under the circumstances, we doubt not Mr. Woodbury will willingly supply you at a moderate expense.

BEEES WINTERED IN THE UNICOMB HIVE.

I deem it worth mentioning, that I have managed for the first time to preserve a unicombe hive alive through winter and spring. In former years my observatory hives were always visited with dysentery in winter, and died out before the middle of March. To preserve the requisite degree of heat in such hives, the bees must draw very largely upon their stores; and if confined by reason of cold only ten days or a fortnight, their bodies become surcharged, and death or dysentery follows.

About the end of December last, the unicombe I speak of had dwindled down, through dysentery, to the merest handful of bees, and I had no expectation of preserving any bees alive in it till the middle or end of January. It occurred to me, however, that it might answer a good end were I to line the interior of the glass with paper to within 3 inches of the top. I did so, and angred well of the process, from seeing the excellent article of Mr. Langstroth on the employment of woollen cloth as a covering for wooden hives in winter. As soon as the paper was fouled by discharges, I renewed it. The bees lived and were healthy, and on the 22nd of March the queen commenced egg-laying. Unfortunately not an egg has been hatched to life, owing to the very small number of bees, and the hitherto ungenial season; but on the 8th of May the queen and her daily diminishing retinue were alive and vigorous, and, as the experiment succeeded in most hopeless circumstances, I have since joined the few surviving bees to another hive.

In the course of my experiments some interesting facts in connection with dysentery were evolved. For instance: a high wind blowing in at the mouth of the hive invariably brought on an attack, causing as it did the consumption of food to be doubled. Several times the bees approximated the description given by Mr. Woodbury of the complaint which he hypothetically termed dropsy. At the close of a gale many of them were greatly swollen, and emitted a fluid nearly transparent.

The advantage arising from the paper lining consisted in the facility of ascent which it afforded to the bees seeking egress in vain. A bee labouring under retention of the faeces has very great difficulty in ascending the cold glass, and often perishes in the effort. This accounts for so many in a dying state being found at the bottom of a unicombe glass hive after a cold night. From what came under my observation, I have little doubt that a paper lining would prove a benefit to box hives in preserving them from internal moisture, but as yet I have only partially tested it.

Contrary to expectation, I have two hives in boxes made of half-inch wood, which have wintered uncommonly well. They were unprotected in any way, and one of them contained only six frames. Though not intended for the purpose, they are at this moment good stock hives. Frequently in March, at 9 a.m., the thermometer indicated 14° of frost, but it did not seem to affect the bees in the very least, notwithstanding the thin walls protecting them. It must be confessed, however, that the past winter has, on the whole, been very favourable to the apiary. True, the hives are in a backward state, but a little

fine weather now would soon put them into a very flourishing condition.—R. S.

OUR LETTER BOX.

RAT TRAP (S. J. S.).—Our correspondent wishes to know where "Uncle James's Infallible Rat Trap" mentioned by the Rev. Mr. Rodwell, is to be purchased. We never found any traps superior to the common drop trap and the steel trap.

QUANTITY OF FOOD FOR FOWLS (Constant Reader).—It is an utter impossibility to answer your question. It depends entirely on whether there is any food obtained by them beside that which is given by hand. Farmyards, gardens, and grass fields teem with food for fowls and Turkeys. Ditchies do the same for Ducks. You can easily make your own calculation. Feed one day yourself, let no one else have anything to do with it. Measure the food carefully. Give none but that which is thrown on the ground, and throw only so long as they will run after it; let none remain uneaten. Feed morning and evening, with a moderate midday meal. The quantity will be a correct consumption to allow. It will differ somewhat at times; birds eat more in the winter than the summer, and those that come from hard quarters will, for a few days, eat voraciously; but they soon settle down to an average.

TEMPERATURE OF INCUBATOR (H. J. B.).—The proper heat in a hatching-machine is 104°. We are not able to state at present what maximum and minimum temperatures destroy vitality in eggs; but we are making experiments, and you shall hear the result. An extreme heat is, we think, more fatal than cold. Minus's incubators can now be had, and are generally successful. Our columns contain the advertisement of them.

SPANISH CHICKENS (J. C.).—The principal thing to do is to induce as much growth as possible in your chickens. Let them have all the sun they can get. The semi-dark and confining process is necessary only with adults. The white face, so advantageous in Spanish chickens, is with them a result of maturity, and maturity can only be advanced or encouraged by taking every natural advantage. Fresh air and exercise are important ones. The fatter your chickens grow the more their good points will be developed. You can show them as chickens till the end of the year, and afterwards, wherever there is a class for birds of 1866. After the fates are become quite white, it is well not to allow them too much light for some days before they go to a show.

COCHIN CHINA EGGS UNFERTILE (J. T. J.).—You do not say whether all the eggs from this hen were unfertile. Those you mention are called "clear eggs," and would be as apparently fresh after being under a hen six months as they were the day they were put under. It admits of very easy explanation. There is no germ of life in the egg, and consequently there is no development; there is no life, and therefore can be no death; no chicken even if well sat on; no decay as if partly hatched and then neglected. We do not think much of your food; to add bran to the meal, to stimulate digestion without giving it food to act upon. The attention of the cock has nothing to do with producing eggs, it only fertilises them. With regard to the one hen, we have long learnt, that cocks have their likes and their dislikes among their hens, and this will often explain why many had eggs come out of a pen. It is not the fault but the fancy of the cock. It would seem to be in low condition, and we advise you to alter your feeding, by giving oatmeal or ground oats morning and evening, with whole corn in the middle of the day. We answer your question as to the sterility of the eggs, believing it has occurred now, lately; if it happened in the winter, there might be other reasons.

EGG-EATING HENS (E. M.).—It is believed that hens, in the first instance, eat their eggs because they require the shell to form that of eggs to be laid. They like the contents, and eat afterwards for that reason. One egg-eater will inoculate a whole yard with the practice. The best plan is to put some hard composition eggs in the nest, and to lay one or two about their haunts. They get tired of pecking these. Watch the chief culprit for a few days, and as soon as she has laid drive her from the nest and take the egg.

BARLEY-MEAL AS A FOOD (G. V. T.).—As a rule, fowls have great digestive powers, and meal possesses enough of the bran element to stimulate them without adding more, unless it be for convenience of storage or transit. We do not see what you gain by making bread or biscuit of your meal. Shake it with water; that is no more trouble than soaking the biscuit, and you save the labour and expense of making and baking biscuit. A more direct answer to your question is to say, bread or biscuit made of barley-meal, without the addition of extra bran, and soaked, will be very good food for poultry.

EGGS BECOMING PALEN, &c. (New Subscriber).—You have little to complain of. Your fowls have laid and done well during three months. Towards the end of the laying it is common for the eggs to get lighter. Nature is getting tired. Much of the shabbiness of the plumage may be attributed to the long-continued attentions of the cock; the rest to the fact they have worn the same clothing ever since last autumn, and it is getting shabby. As soon as they leave off since last autumn, and it is getting shabby, the egg will be diverted into another channel, and will supply fresh clothing. Potatoes are not good food for fowls confined in a small space. They are not nutritive enough. Your midday meal is good; let that in the morning and evening consist of oatmeal slaked with water. Brewer's grains are too stimulating, and act injuriously.

PHŒASANT MALAY (A. L. B.).—The Phœasant Malay has a plumage of very dark rich chestnut, with darker black, tail, and thighs. The hens are more or less spangled in most cases, and the resemblance to the breast of a cock Phœasant has earned them their present name. The combs are red, rough, and flattened on the head; the legs should be yellow. They have other points in common with ordinary Malays. The cock has a darker saddle. They are not Game fowls. Their origin is from the East, but they have been crossed in England with Golden-spangled Hamburgs. The hens weigh about 4 lbs., the cocks 6 lbs., each. The Versicolor Phœasant is a native of Japan. It is not larger than our English birds. A pair of pure birds is worth about £14. Their colour is a rich purple, varying in shade and brilliancy with every motion of the bird.

BEE-BOOK FOR A BEGINNER—ORNAMENTAL HIVE (H. S., Gedney).—"Bee-keeping for the Many" sent free from this office for five stamps. Messrs. Neighbour, 149, Regent Street, and 127, Holborn, or Mr. Pettitt, Snargate Street, Dover, supply ornamental hives.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 69.9°; and its night temperature 47.4. The greatest heat was 99°, on the 6th and 7th, 1846; and the lowest cold 34°, on the 9th, 1862. The greatest fall of rain was 1.18 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

CULTIVATION OF THE FIG.
ON WALLS.

FOR the growth of Figs in our climate a south aspect is indispensable. The trees will grow, and show fruit plentifully on east and west aspects so far north as the

Tweed, and yet they rarely, if ever, ripen a crop. Even on south walls in exposed and elevated situations the fruit ripens seldom rather than in general.

SOIL.—The Fig tree does best on a warm soil—good sandy or light loam on gravel, and on such soil it will ripen a crop in the majority of seasons. On the other hand, if the soil is strong and cold the growth is great, and the fruit are large, but they ripen only occasionally, as during a sunny and hot summer like the last. Unless the soil be rather light and shallow, gravelly, and well drained naturally, borders affording these conditions should be formed. Dig out the soil to the depth of 2 feet 3 inches, and let the bottom slope from the wall to the front of the border, where there should be a drain to carry off the water. The bottom should be covered with 3 inches of concrete, which may consist of lime riddlings laid on in thin layers, and beaten firm—it cannot be rammed too firmly; and on this place 6 inches of brickbats, broken stones, and similar materials. There will then be depth for 18 inches of soil, which may consist of the top 6 inches of a pasture where the soil is a loam of medium texture, and if there is gravel under, and even in the soil, all the better. Place a layer of the turf, grass side downwards, upon the drainage, and then the remainder, chopping it a little with a spade. The width of the border should be equal to the height of the wall. If the soil contains no gravel, one-sixth of brick and old mortar rubbish may be mixed with it. This will be a sufficiently rich soil for the Fig tree; for the difficulty is not in obtaining growth, but in securing strong close-jointed wood. For this reason the border should be made firm, for if the soil be free or loose the shoots will be long, and the leaves far between; and if the roots have an unlimited space to feed over, great abundance of wood and leaves will be the result. The roots, therefore, in rich soils should be confined within proper limits, or kept in poorer soil. On gravelly hungry soils these precautions are, of course, unnecessary, for on such the Fig grows sufficiently, and the less it grows the earlier it will show its fruit, and the chances of ripening are increased. It is an easy matter to make up for any deficiency in the richness of the soil by top-dressings of manure and copious waterings during dry weather, whilst it is difficult to control a Fig tree in rich soil by manipulations or stopping the branches.

PLANTING should be performed in the spring, before the trees begin growing, and the distance apart should be

20 feet for a 10 or 12-foot wall. Rather high walls are best, for the shoots of the Fig tree are rarely inclined to take a horizontal direction, but almost always seek the top of the wall. In planting the ball should be broken, and the roots disentangled; lay the roots regularly on the surface of the border, and cover them with 1 inches of soil; this will give the appearance of a mound, which is all the better, as the top-dressings will raise the border, and in time sink the collar, which at all times it is desirable, and especially with fruit trees, to keep slightly elevated. The trees may also be planted in summer, when in full leaf, from pots. Giving a good watering after planting and during very dry weather will be all the attention needed during the first year.

THE BEST KIND OF TREES TO PLANT are those with one-foot stems; for when those with no stem are planted a number of shoots spring from a level with and even below the ground line, creating continual trouble, and weakening the tree to no purpose. Eyes put in in February or March will by midsummer have made a growth of 15 inches. The point being then pinched out, three or more shoots will mostly come from the upper part of the plant, as shown in fig. 1. This is what is generally termed heading a maiden tree. This is the tree I would plant. It will not require stopping again the first year, but in spring, after planting,

Fig. 1.

Fig. 2.

it will put forth more shoots than one from the point of each shoot. If all but two be rubbed off we shall by midsummer have the shape of tree represented in fig. 2. When five leaves are made, take out the points of the shoot at that. This stopping will give rise to two or more shoots, but only two of these are to be retained. If only one shoot come from or with the spring growth it is of no consequence, only stop that one at the fifth leaf. Distribute the shoots so that an evenly-balanced fan-shaped tree may be produced, allowing a distance of 9 inches between the branches, and by continuing to stop the spring shoots at the fifth leaf so long as the trees exist, sufficient side shoots will be produced to cover the wall evenly in every part; and whenever a deficiency of young shoots occurs in any part, they must be encouraged from the base of the branch so becoming bare, and after a year or two's growth the old branch may be in part or entirely removed.

From the almost constant necessity of cutting out the old wood preference is given by many to what may not inaptly be termed the stool tree, or that having many stems rising from near and below the soil. These trees never have the shoots stopped, but are allowed to grow as long as they will, training any shoots that may be produced from them so as to fill up vacant spaces, and when the old

parts become naked these give place to a new and young shoot, which in its turn is served in the same manner. By this system there is no difficulty in keeping the tree furnished with young wood, without which there can be no crop, the difficulty being rather in the opposite direction—viz., that of keeping the suckers from crowding the base of the tree. This kind of tree is represented in *fig. 3*.

It is rarely that we see standard Fig trees against walls. These, however, are most productive, for the mode of training seems to check the flow of the sap, and to concentrate it more fully on the fruit. Standards are desirable when a high wall is to be covered, as will be obvious from *fig. 4*. The trees are prepared in the same manner as those on one-foot-stems, only they are allowed to grow with a straight stem to a height of 6 feet, and are then stopped, and three shoots are allowed to grow upon the side branches, after stopping, instead of two, as in the former case.

Fig. 3.

which will cause the production of one at least, if not two, shoots, which are the midsummer shoots, as they are called, and upon these the crops that ripen are borne.

As the Figs are produced on wood of the previous year, and this never bears fruit again, young wood must be laid in so as to keep up a succession of it in all parts of the tree; and when any part becomes naked or deficient of bearing wood, that part should be cut out, and young wood brought up or down to fill the space. The best time to cut out the old wood is in spring, and when it can be done remove an old branch to the stem. After this the knife should not be used for a twelvemonth, in the interval merely disbudbing so as to have the growing shoots 1 foot apart, and stopping the shoots with the finger and thumb.

PROTECTION.—In our climate the Fig is not hardy, though it will survive in the majority of seasons; yet the fruit of the size of Cob nuts mostly perish, or are so injured as to fall in spring, if the trees are unprotected during winter, and in very severe winters the trees are often severely injured. In 1860, Fig trees in many places south of London were killed to the ground by the severe frost of December 25th. It is not safe to trust them without protection north of London, and even there the

Fig. 4.

Fig. 4 shows the trees three years trained, by which it will be seen that a shoot is encouraged in the second year between the stem of the tree and the point at which the first stopping has taken place, and others between the several years' growth all along the main branches, and also upon the secondary ones, by which means the tree is kept furnished with bearing wood from the stem to the extremities of the branches.

PRUNING.—Figs upon walls produce their fruit upon the wood of the previous year. The spring shoots produce fruit which for the most part attains a good size, especially when such shoots are not stopped, but it never ripens, at least I am not aware of their ripening the second crop in England. If the spring shoots be not stopped they will grow a foot or more in length, and show no fruit; but after the first growth the second begins, and is remarkable for the stoutness of the wood and closeness of the joints, at every one of which, in the axils of the leaves, a little Fig will show itself. These short close-jointed growths afford the fruit that ripens in the following year. Without stopping it is rare that the shoots show fruit till they are a foot long, and then it is at their extremities only. This is the popular system of growing Figs, which wastes a foot space to secure from 3 to 6 inches of bearing wood, and is a most prolific source of naked branches.

Now, as the spring shoots are of no use for bearing, and waste the energies of the tree, their preservation is only essential as a means of obtaining wood to fruit in the following year. When the spring shoots have made five leaves pinch out the point at the fifth leaf. This will cause fruit to form in the axils of the leaves, and new, short, spur-like shoots to issue at the same time. These will show fruit by autumn, or it will be sufficiently formed in embryo to come in spring, and ripen in the autumn, whilst the fruit upon the spring shoots will attain a full size, but will not ripen, owing to a deficiency of heat. The spring shoots, therefore, as they produce a crop which does not ripen, should be kept in as little room as possible, and may safely be reduced to three joints, though when the tree is very vigorous it is better to stop at the fifth leaf,

trees must be protected, otherwise the largest of the young fruit will fall in spring or wither upon the trees, and the prospect of obtaining ripe Figs early in August will be destroyed. There is little prospect of obtaining a crop of Figs unless the trees are protected, for if the young Figs are fairly visible in autumn when the leaves are shed, and of the size of pea up to that of hazel nuts, they will not on an average of seasons ripen until the end of September, and very often not at all.

When the leaves have fallen a dry day should be chosen, and the trees, having their branches loosened from the wall and tied together, should be covered up for the winter. Some remove all fruit larger than a hazel nut, entertaining the opinion that if left it never ripens, which though generally correct sometimes does not hold good, for I have gathered what were large green Figs in the previous autumn ripe and very large early in August, whilst those of the size of a hazel nut or less were not ripe until the third week in August, or first fortnight in September. Had all the large Figs been removed the crop would not have been so early, nor would ripe Figs from the same tree have been produced for so long by weeks. In what way these large Figs can injure or rob the other Figs when the trees are at rest is to me inexplicable; and if they are so injured as not to swell in spring, they certainly do not rob those left of support, as it has been asserted they do. I think the removal of green Figs in autumn injurious to the tree rather than beneficial, for it cannot be effected without force, and Nature can do it herself in spring without any one knowing that the fruit had not ripened off.

Leaving, however, these matters of mere opinion and reasoning—the trees being loosened from the wall and brought into as little compass as possible without breaking them, place 3 inches of dry straw between the wall and the shoots, from the bottom to the top, fastening the shoots against the straw as the work proceeds. This will keep the straw up. Let the straw also extend beyond the spread of the branches, and cover these with 6 inches of straight straw, fastening it with tarred string. A thatcher will do this so that wet cannot

enter, and the Fig branches will thus be as dry as if they were in the middle of a haystack. The trees should be covered up in the above manner during the first dry period after the leaves have fallen, and before severe frosts occur. In this condition the trees may remain until the beginning of April, when the covering should be entirely removed during mild weather, and the trees protected at night and during frosty days with a double thickness of mats, removing them during mild weather. When signs of growth appear take off the covering by day in mild weather, but protect at night until danger from frost is past. The double covering of mats should be gradually reduced, first by removing one mat, and then withdrawing the other when danger is no longer apprehended. Under these circumstances the swelling and ripening of large green autumn Figs is not uncommon; but when a covering of a couple of mats only is given, then it is useless to expect them to ripen, though they may do so after an unusually mild winter.

The past season has been very favourable to the ripening of Figs, and in more than one instance have large autumn Figs survived the winter, and ripened at an earlier season than usual. The Fig noticed by "H., *St. Boniface Cottage, Ventnor*" (Vol. IX., page 91), was undoubtedly one of these large autumn Figs, as they are called, being a very early one, indeed the earliest ripe out-door Fig recorded in this country. I have a note of one gathered on the 3rd of August, from a wall so far north as West Yorkshire. "H.'s" Fig so satisfactorily accounted for by "G. S.," at page 129 of the same volume, being the earliest recorded, I should like to know if there has been gathered in England a ripe Fig from the open wall prior to the 24th of July.

I may take this opportunity of thanking "G. S." for his hints on obtaining a third crop of Figs, and in his views I fully concur. What I had producing three crops was the Brown Turkey in a forcing-house. The Early Violet gives three crops very easily in a forcing-house, and is, besides, the hardest of all, and a most abundant bearer, but the fruit is small, and in my opinion not much in point of flavour. In an orchard-house in Yorkshire, except in 1859, it did not yield two crops, so that "G. S." has an advantage over northern cultivators. It produces two crops, ripening early in a heated house, such as a vinery, with occasional fire heat, or Peach-house having a little fire in spring to keep out frost, and in autumn to ripen the fruit and wood. The Brown Turkey and White Marseilles also ripen two crops in such houses, with occasional fire heat, in spring and autumn.

When the trees are only protected by a covering of mats during severe weather in winter, it is useless to leave the green Figs larger than a pea, all the others should be cut off with a sharp knife by the time the leaves fall. In our climate the Fig is usually leafless by the commencement of November, and begins to grow about the middle of May.

When the growth of the trees is weak, and the fruit small, a top-dressing of manure should be given in autumn, pointing in the short dung, and removing the litters portion in spring. This will not only protect the roots from frost, but enrich the soil. During very dry weather a good watering with liquid manure at 90°, will contribute to increase the size of the fruit, and to keep it on the trees.

The best kinds for walls are the Brown Turkey or Lee's Perpetual, White Marseilles or Naples, Brunswick; and for earliness and productiveness, the Early Violet may be added.

In conclusion, I would say, Avoid a rich soil, keep the shoots thin, have every part of the wall covered with young wood, tolerate no long bare shoots, protect the trees from frost, keeping the growth short; and if it is desired to obtain fruit with certainty, cover the wall and border with glass, having standard and dwarf trees planted in the border, or in pots standing upon it, and, to secure two crops, run two four-inch hot-water pipes along the front.—G. ABBEY.

SOWING VERBENA SEED.

UNDER this heading Mr. T. Pointon writes (page 405), commenting on some statements contained in one of my articles on the above subject. I agree with Mr. Pointon, that some seeds of the strong-habited kinds will vegetate in a fortnight; whilst others will not, as I stated in the article he comments upon, vegetate in two years.

Mr. Pointon must allow me, as the raiser of many good Verbenas, to be capable of describing my mode of treatment, and I believe my name is sufficiently well known to the readers of

THE JOURNAL OF HORTICULTURE, as a raiser of new plants, to inspire them with confidence in my statements. I have now a great number of small seedling Verbenas just peeping up, the seeds of which were sown in December, 1865. These, however, are from a bed where the seed-pans had been emptied out, as described in my former communication. I need not go so far as Birmingham to see a lot of seedling Verbenas, as I have in my possession some thousands. Many of them, I am happy to say, are very great improvements on existing varieties, and many of them destined to be the pioneers of a new race of that very popular plant. Should chance bring Mr. Pointon this way, I should be very happy to show him my stock. In the meantime, will Mr. Pointon kindly favour us with a paper for the Journal, describing his mode of treating the Verbena from seed or otherwise?—J. WILLS.

THE STORY OF MY FIRST ORCHID.

[We have lived—we will not say how many years—under the conviction that young writers, especially of the *Eve* variety, have great awe of editors, classing them with ogres, literally making their bread of correspondents' brains, and drinking from cups formed from authors' skulls; but the following communication dispels the conviction we had. It was accompanied by a note in which our ears are boxed with this sentence—"Editors, like other people, are difficult to please." We resolved at once to show Miss Maud that we are not difficult to please by inserting her "scrap," as she calls it in the note aforesaid—(rather a good retort that!) and by assuring her that we will insert such "scraps" as often as she pleases to send them, and the oftener she is so pleased the better.—EDS.]

I HAD a Dendrobium noble given me once—I think it was in the May or June of 186—. I must confess I did not know what to do with it; its thick white waxy roots were bare of soil. I had grown many things, but never an Orchid—the name sounded very terrible to me.

To ask our gardener would have been useless, for he would not grow Orchids—"didn't like them."

After a great deal of thinking I potted my plant after the directions given by some learned man, and yet with a vague idea that I only half understood him; but then, I fancy, gardeners' descriptions are like the cook's receipt, the most essential ingredient left out.

The Dendrobium grew and flourished. In the following year, as the young shoots grew, the leaves fell off from the old stem. I became very uneasy and sought professional advice. "Oh, the thing is dead, clean dead, sure enough," said one, "you have pinched it of water; the young ones may live, though, if you can winter them, but they are scratchey things to manage." "Your plant is not dead," said number-three gardener, whose opinion I sought, "it is in first-rate condition, will flower next spring; never does flower until the leaves fall off, and the stem is well dried-in."

"Will those dried bits of stick ever flower again?" I asked. "Yes," said one. "No," said another; "and whatever you do never let a drop of water touch your Dendrobium; that is the secret of Orchid-growing."

Another said, "Water it overhead many times a-day; it will not do without moisture."

Now, I did not do as the old man in the story did with his ass—if I had been a man probably I should—then my poor plant would have gone to the rubbish-heap; but being a girl—a woman—I did not take all for gospel. So I watered my Orchid when it needed it, which was very often during the hot summer weather. I kept it very clean, and think that is a secret of Orchid-growing, and when the autumn came and the heat lessened, I gave it less and less, sometimes sponging the leaves, and often dusting them with a clean handkerchief. Whether the treatment was right or wrong the plant grew and flourished.

In the autumn of that year there came a time of grief, and it was left untended for days, pushed out of sight behind a large Crenate Cactus—left, indeed, to its fate. Never shall I forget its appearance when pulled into the light; it was covered all over with the red spider: there needed no glass to find the insects out, they were plain enough even to the naked eye. Up and down the poor leaves they hurried in ceaseless crowds—hundreds, nay, thousands of them. Never was Rotten Row busier or gayer than those leaves as they stood in the full glare of the sunshine, red and yellow, and white and yellow green. There were fathers and grandfathers, and little ones, meeting

and passing and going on their way, as if each one had a special mission to perform, something to do besides life's sustenance to provide, and all this with an apparent enjoyment.

I watched them for a few minutes, then the syringe and cold soft water thinned their numbers—cut them down like the plague or rinderpest. The few left appeared to become larger and fatter, as if rejoicing in the rich pasturage; they were not left there long—no mercy was shown. In a week my Dendrobium was clean. The red spiders never came to it again; if they ever thought to do so, they were scared by some patriarchal hermit telling the sad tale of the terrible destruction of their "noble" city, and the almost total annihilation of the red tribe. Yes, the flood and storm and tempest had indeed swept over them, and the wonder where they had gone to could only be answered by the greater wonder where they had come from.

So for a short time the poor Orchid was at peace. It was no favourite save with its owner, and one thing must be said of it—it was like an ungainly child, attracting attention but never admiration. "I do not know what the thing is grown for," said the master, "a mere piece of stick—rubbish!" "It will never flower," said the gardener, "but be always just as it is now." "It is very crooked, let me straighten and tie it up for you," said cousin Walter (just home from school, where he had taken the first prize for botany, and of course he was very proud), "and allow me to rub off those strange protuberances." I screamed out "Stop, will you!" but it was all in vain, for suiting the action to the word, away went clusters of would-be buds. "Don't get into a passion, Maud. You will never make me believe the flowers come before the leaves, it is against Nature. Why, child, the leaves come to feed the flowers!" "You are a dunce, cousin Walter, with all your book learning. It never will have leaves on again; I am not sure it will ever flower after what you have done. I have cared for it, watered it, and kept it clean, and loved it for nearly two years, all for your great rough hands to knock off." "Nonsense, child, it never meant to flower there, or if it did, why there are lots of buds left. But see, I will show you where the flowers come from—out of the pseudo-bulb down here, and there is not the least appearance of growth." And cousin Walter pushed it close to a damp wall, and I tried hard to forget it, not even going to look at it for more than a week. When I did go, to my great surprise I found it standing in a warm, sunny place in a forcing-vinery. The flower-buds, unmistakable, were swelling on the old stems, and the leaves on the resting shoots were green, and thick, and leathery. Two or three weeks more and then out it burst into marvellous beauty, seeming to do all its work one moonlight night. There were five, seven—twelve blooms, all opening as if by magic to the May sun. And then the household flocked out to see the new flower, and the master said, "Who would have thought it!" and the gardener, "I could not have believed it; but then I never had much to do with such things." And cousin Walter lifted his hat to the fair lady flower, and said softly, "Oh! Maud, I am so sorry I knocked off the buds." And I looked at it, and loved it more, and said, "I will never part with it, for it was a gift," and the giver had gone "far away." So the troubles of the Dendrobium noble were at an end.—MAUD.

LORD LYON PELARGONIUM.

In your report of the International Horticultural Exhibition I observe your reporter says: "Why Lord Lyon [Pelargonium] did not receive a first-class certificate we do not know." Permit me, as a great admirer and a grower in a small way of Pelargoniums, to express my great surprise that this really splendid flower was passed over by the gentlemen who awarded certificates to Alfred and Favourite. To my mind neither of these flowers was at all equal to Lord Lyon. It is possible, for I only saw the flowers on the Friday, that Lord Lyon might not have had a good bloom on it when the awards were made; if it had, I am unable to conceive any reason for passing it over.—P.

MESSRS. WATERER & GODFREY'S SHOW OF AMERICAN PLANTS in the Royal Horticultural Society's garden at South Kensington has just been opened, and will well repay a visit. Besides plants in splendid bloom of the best of the older kinds of Rhododendrons, and others rapidly coming on, there are several seedlings shown for the first time. These, and the exhibition generally, we hope to notice next week.

TOBACCO CULTURE IN ENGLAND

The growth of Tobacco for fumigating, ornamental, or other purposes is a subject of some importance to the readers of this Journal, consequently I forward for insertion the following correspondence, the replies to my letters coming from an official source—viz., Inland Revenue, Somerset House:—

"SIR,—Can you inform me how much Tobacco, to be used simply and solely for fumigating purposes in greenhouses, may be grown on English, Scotch, or Irish soil without infringing the law? May the quantity planted exceed one-half of one pole? See sec. 1 of 1 & 2 William IV., c. 13 (1831.) Is any person who grows more than the above-mentioned quantity for fumigating purposes, or 'who sets, plants, or improves to grow' any Tobacco plants for ornamental purposes liable to a penalty, and if so, would that penalty be enforced?—X."

"SIR,—I am desired to acquaint you, in reply to your inquiries of the 1st inst., that the growth of Tobacco is absolutely prohibited in the United Kingdom, with the exceptions of any physic garden of either University, or a private garden for chirurgery, and in this case the quantity planted is not to exceed half a pole. The penalty for planting in any case, with the above exceptions, is £12 for every rod or pole of ground, and the Board would certainly feel it to be their duty to enforce the law in this respect.—W. C."

"SIR,—I am much obliged to you for your letter of the 5th inst., and the information contained therein. The only point I am now uncertain about is whether the word 'chirurgery' includes Tobacco grown simply and solely to destroy insects, &c., on plants in greenhouses or elsewhere in a private garden.—X."

"P.S.—As the subject is of great importance to gardeners and others who do not wish to break the law, would you mind my sending copies of my letters and of the replies for insertion in a Journal where the subject is now under discussion, as the law is at present imperfectly understood?"

"SIR,—Having laid before the Board your further letter of the 7th inst., I am desired to acquaint you in reply, that the exception to the absolute prohibition of the growth of Tobacco in the United Kingdom in favour of a private garden for chirurgery would certainly not extend to the growth of that article for the purpose of destroying insects on plants in greenhouses or elsewhere in a private garden. The Acts containing the prohibition and exceptions are the 12 Charles II., c. 31, 15 Charles II., c. 7, and the 1 & 2 William IV., c. 13. I am to add, that the Board have no objection to the publication of this correspondence if you desire it.—W. C."

The Acts mentioned will be found referred to at page 237 of your Journal.—X., Surrey.

NEW BOOK.

Garden Architecture and Landscape Gardening. By JOHN ARTHUR HUGHES. London: Longman & Co.

This is a useful and clever book, but, which was not to be expected, it is also an amusing book. It would be amusing if it were only by the style in which it is written. Gratiano tells us that "there are a sort of men" who so deport themselves as if they would say—

"I am Sir Oracle,

And when I ope my lips, let no dog bark!"

Gratiano, however, did not confess that he was one thus seemingly "dress'd in an opinion of profound conceit;" but Mr. Hughes does not shrink from such confession, and so enamoured is he of his own conceits, that he blazons both at the commencement and conclusion of his volume, that he feels that no apology is needed for its "apparent dogmatism." Apparent! Why it is dogmatism pure and simple from end to end. We do not intimate that the dogmas are erroneous; but, then, if we are heretical enough not to believe in some, we are made to feel at the time that if our author were Grand Inquisitor of an architectural Inquisition, we should promptly be the prime performers in an *auto da fé*.

For example, he begins by saying "UNITY, that is to say, breadth." Now we, not having the fear of the Inquisitor to deter us, venture to say that "Unity is not breadth." There must be unity to render breadth pleasing, but they are not identical. Unity may be achieved even in a narrow space. Unity and harmony are synonymous in our opinion. Again, in illustrating "breadth," Mr. Hughes says that balustrades at the end of a walk should be divided by two piers into three

voids. Now, here we venture to differ from him. One pier in the centre, and only one void on each side, in our opinion gives a greater breadth, and is most pleasing to the eye.

As "breadth" required ten pages of illustration, we anticipated that to "variety" and "contrast" at least as many would have been devoted; but Mr. Hughes dismisses them thus—"The writer does not think that variety and contrast need any special illustrations, inasmuch as every one knows what is meant by these terms." It is quite true that every one knows what is meant by "variety," but it is quite as true that in garden arrangements nothing is more difficult to attain than harmonious variety.

Having thus dared to differ, let us next give a few brief extracts in justification of our opinion that it is a useful and clever work.

PARISH MAPS.—To many of our readers it will be new and useful information, that "there is a public office in St. James's Square, where may be found the map of every parish in England, and where a copy of any portion can be obtained for a very small sum, and in a very short time."

TREES NEAR THE HOUSE AND LAWN.—"Trees in any considerable quantity should not be suffered very near the house; they are causes of much damp. A Cedar is one of the least objectionable trees for such a situation, as it is dry in itself, does not check the current of air like an Elm or Beech, nor does it hold such a body of damp. The Pinaster is equally free from objection. A Yew or Thorn will do no harm, because they are mostly of small size, and will not screen large portions of the walls from the sun and wind. But when large Elms, Beeches, and Sycamores, are allowed to almost overhang the roofs, choking the gutters, darkening the rooms, and covering walls and roof with a green deposit, it is time for the sanitary inspector to interfere.

"All writers on landscape gardening agree that a backing of trees is the best that can be obtained; and if there is any piece of timber on the ground which would form even the nucleus of an extensive plantation, its situation with respect to the house should be well considered. A house should not be nearer to a wood than 50 yards, but may be within half that distance of a mere row of trees. Some trees of a very marked character are necessary in the vicinity of the house, to give individuality to the place. Cedars and Wellingtonias are very well suited for this purpose. The Larch, when well grown, is a most graceful tree, little inferior to the Cedar. A Chestnut gives great character; as does a Tulip Tree. The Spanish Chestnut is very ornamental, but is only suitable where the park comes very close to the house.

"In settling the space to be occupied by the lawn, recollect the expense of keeping it in high order, and that every square yard adds to that expense; do not, therefore, give it too magnificent proportions on your plan, unless you are sure it will be kept up at that size.

"Nothing has a more comfortable English appearance than a well-kept lawn, though it cannot be valued as it deserves except by those who have missed it in foreign lands, where the well-shaven velvet lawn is unknown."

STYLE OF GARDENS.—"The style of the garden may at all times be later than that of the house. Changes of fashion and taste would affect the garden sooner than the house. In the one the whole external and internal decoration would have to be changed at great cost; in the other it is only the trouble of making or destroying a few walks and beds. A few loads of earth to make a bank, and a few yards of cutting, will materially alter the style of a garden; and as we are prepared for greater caprice, we are not shocked at slight incongruities. In digging up almost any old garden, remains of still older can be traced, and this in cases where we know the house itself has not been altered.

"The writer has always thought that the architecture of gardens should be to a certain extent florid—that is to say, more so than the house. Perhaps it is, that being in the midst of flowers, leaves, tendrils, and delicate forms generally, the transition to extreme simplicity is too violent, and shocks the spectator.

"As an example: A perfectly plain die or pedestal of polished granite or marble would be considered quite good enough, and, indeed, most appropriate to support a handsome vase, tazza, or bust, if within-doors, whether in sculpture-gallery, hall, library, or observatory, yet this does not look well in a garden, where a pedestal of fantastically carved freestone would be more pleasing. The glitter of the polished surface is destructive to all repose."

We cannot afford space for more extracts, although we have many marked. The work is illustrated by more than 130 excellent woodcuts, which render the author's directions and opinions readily understood.

PROPRIETORSHIP IN HOME-GROWN SEEDS.

A GARDENER having collected and dried seeds, having first supplied his master's garden, is the overplus the property of his master or for the gardener's own disposal?—X. Y. Z.

[The seeds belong to the master. His soil produced them, and he paid for the labour which cultivated and dressed them.—Eds.]

A PEEP AT THE WOODS IN ODD PLACES.—No. 5.

OIL PALM—CANE.

HAVING had a peep at the Mangrove, and a few of its companions, I will now show a much more elegant, though not so noble a tree, the one being an exogen, and the other an endogen. Before showing the lovely Oil Palm (*Elaeis guineensis*), I must ask my reader to follow me out of the Bonny river, where we are at present lying, into the New Calabar river—(these so-called rivers are only different arms of the delta of the Niger, to which sailors give these titles in consequence of the respective towns standing on them; thus amongst seafaring men the Thames is almost invariably called the London river, and the Mersey the Liverpool river)—and let us pass up stream through the salt marsh district until we reach the higher country, in which the *Elaeis guineensis* grows. As we want water for the ship, we will take a boat and some water-casks to bring it back, the boat's crew being composed of Crewe boys, since white men cannot stand the labour of rowing in the sun so well, and are more valuable on board the vessel.

The boat is now ready, so we will away. Between the Bonny and New Calabar river is a narrow channel formed by an island on one side, and a gently rising headland, or rather sandbank, on the other. This headland is most richly covered with fine Mangrove timber, and presents a very beautiful appearance, yet in spite of its beauty it bears a very evil name, being called Crucifixion Point, on account of a most horrible transaction said to have taken place there, in which a boat's crew were captured by the natives and eaten, with the exception of the officer in charge, who was crucified on one of the trees, head downwards, and there left to die. He was discovered and taken on board his ship, where he lived long enough to narrate the story, and then expired. Though numbers of the natives snuffed for this foul deed, the actual perpetrators were never known, but one chief in particular was suspected on account of his acknowledged detestation of the whites, and his penchant for cannibalism. Our boat, however, has fortunately escaped safely through the pass, and is now floating in the New Calabar river, so let us turn our faces up the stream, and make the best of our way to the town, for here we shall have to stop for a few hours to enable us to obtain a native to act as pilot and interpreter, for we are going into a country in which neither English nor the Crewe language is spoken or understood; and as we shall be compelled to hold some communication with the natives of the different territories through which we must pass, all of whom are troubled with the bumps of pugnacity and cannibalism, it would be unpleasant not to know what they mean, should they tell us to stand and deliver some portion of our goods, or demand an explanation of our presence in that country. We should, of course, feel it extremely unpolished conduct on our part to go on without returning an answer to what might possibly be a polite speech, through our barbarian ignorance of their euphonious language, the verbal mode of communication of any of these tribes seeming to be carried on by sounds varying in sweetness from the bass grunt of a pig to the mellifluous nasal whine of a thorough-bred Yankee.

Passing up a fine wide river lined on both sides with magnificent foliage of all descriptions, from various kinds of grass to enormous timber trees, we came in sight of the vessels lying moored off the town of New Calabar, the natives of which town have, as I see by a recent account in a Liverpool paper, been indulging in their old offence of cannibalism, for having gone to war, or rather made a raid upon the Brassmen, and taken a number of prisoners, they, according to custom, killed and made a feast of them. But this having nothing to do with our present trip to view the Oil Palm, we will leave them, and having taken our guide and pilot (who is likewise responsible

for our welfare) on board, we will proceed on our journey; and as the reach of the river in which the town stands is a long one, we will take this opportunity of describing the guide before entering on the more interesting country. Our pilot is a gentleman of most decided colour, being as black as the ace of spades, with lips of most astounding size; his nose looked as if made of black shoemaker's wax, which one day, whilst its owner had been lying on his back in the sun, having been exposed to too great a heat, had become softened and had flattened and spread over a large portion of his face. Notwithstanding the general want of comeliness of his features, and what would be the whites of the eyes in Europeans, in his being ochre-coloured, the boy, for he was only about fourteen or fifteen years of age, was a very easy, good-tempered being, and contrived to make himself much liked during the time he was with us. He was one of the numerous sons of the king, and a great favourite of his father, consequently, a person of some importance, and, therefore, of no small value to us as a guide, especially as all the tribes through which we went were, to some extent, inimical to whites. After rounding the first bend in the river the stream became narrower and more rapid; and though it was now getting on towards evening we continued to row on, for I was anxious to gain a wider part of the river before dark, which our guide assured me could easily be done if the Crewe boys would row well; and he was right, for success crowned their labours, and we dropped anchor for the night in a fine wide reach, which was about 500 or 600 yards across. We had been pulling since noon through a beautiful vista of noble trees and twining plants, to all appearance growing out of the water, for the land is so low and swampy that it seems scarcely to rise above the level of the water, especially as the most lovely little watery ways open in all directions, looking like green country lanes branching off from the main high road; and here was constantly to be seen a solitary canoe paddling away at full speed, or some lazy old alligator swimming leisurely along. Flocks of parrots, too, screamed about amongst the trees, and now and then a wizen-faced monkey would pop his head round some branch of a tree, and then spring chattering away. With regard to alligators, they here seem to be held in as much respect as the sharks are about Bonny, for we passed a number of small houses about 3 feet square, made of a kind of bamboo frame covered with white calico, on examining which we found some Oil Palm nuts, a pair of live white fowls, and sometimes a kind of cake or bread. These our guide told us were juju—that is, sacred, and were intended as sacrifices to the alligators, with which the river swarms, to propitiate them, and keep them in good humour. Now, we being hungry and partial to poultry, personated their sacred highnesses the alligators, and took the fowls wherever we could lay our hands on them; and I must give our guide credit for being more enlightened, or else sunk in much deeper ignorance than his countrymen generally, for he took to robbing the juju-houses quite as readily, and to the full as eagerly as the unbelieving white men.

Early next morning, indeed before daylight, there being a beautiful moon, we hoist anchor and continued our onward passage. About sunrise we came to an extensive open space more than half a mile across, where a number of the arms of the delta converged, and which was dotted with numerous small islets, most exquisitely clothed with tall green grass, and various kinds of tropical plants, chiefly shrubs. Fancy what must have been our delight on suddenly coming from a long straight strip of water not more than 150 yards across, and closed in on both sides by a wall of tall forest trees, to emerge at once upon a lovely scene like this, especially lighted up by the glorious slanting rays of the rising sun, bright and cloudless as it often is in the tropics, throwing one portion into sombre shade, whilst the other appeared still more brilliantly illuminated by the contrast. It was a scene of such surpassing loveliness, that I have never looked upon the like since, and I have never forgotten it. This beautiful spot stands between the territories of the Cricqui-men and the Booqui-men, and we had not gone far into the possessions of the latter before an amusing incident took place, showing how small the communication is between the whites and these tribes. We saw a party on shore around a fire, and our guide told me they were drying fish, so I asked him to procure some, which after a good deal of coaxing to prevail on them to approach, they never having seen whites before, he managed to effect. He induced these poor wretches, by setting them the example, to taste some ship's biscuit, which seemed to be quite to their liking; he then persuaded them to taste some sugar, which they had no sooner done than they paddled ashore to their companions as

hard as they could go, exclaiming, as our pilot interpreted to us, that the white men had some salt which tasted like honey.

Having passed through the Booqui territory, we at length came to that of the Ebo or Elebo-men, in which the Elais guineensis grows, and where a large portion of the palm oil, obtained in this part of Africa, is manufactured. The inhabitants of this district are a powerful, warlike, treacherous race, and much superior to the tribes surrounding them, all of whom seem to stand more or less in awe of them. Here, then, is to be seen the beautiful Oil Palm. It is a tallish tree, and, like all the other Palms, has a long straight stem and an elegant head of feather-like leaves, beneath which grow clusters of fruit, berries are perhaps the best name for them, which, when fully ripe, are of a deep orange or red colour. These berries being ripe are gathered and placed in a vat, where they are subjected to pressure, and the oil is thus expressed. That which comes first is called not palm oil, but palm butter, and is the very finest of the oil. It is used by the natives as we use butter, and when fresh is a delicious substitute for it, being very much of the consistency of fresh butter, but of a beautiful deep orange colour. The oil after being expressed is put into large casks or puncheons, which are supplied to the natives by the white traders, who are principally in this neighbourhood Liverpool merchants, the trade itself having originated out of the slave trade in the following manner:—The late Sir J. Tobin, of Liverpool, sent out to the coast of Africa a vessel to be loaded with slaves, but whilst she was loading news came that the slave trade was abolished, and, therefore, another cargo had to be found. The vessel being plentifully supplied with soldiers' buttons (then a great article of trade), beads, and other commodities suitable for the traffic in niggers, and palm oil, at that time almost unknown in Europe, being tolerably plentiful, a portion of a cargo was at once procured, enough to bring the ship home in more than ballast trim. This was sold at an enormous profit; and other vessels were at once fitted out to trade for this article, which now forms a large item in the imports of Liverpool.

The oil when brought down to the vessels for sale is often most enormously adulterated, either with water, mud, or sand, and its quality and consequent value as far as these adulterations go is ascertained in the following manner:—A long, steel, half-cylinder, in which are compartments, the flat surface of which is fitted with a slide running the whole length of the instrument, is thrust through the bung-hole to the bottom of the cask, and then the slide, which has been drawn up, is pushed down, of course enclosing a portion of oil in each division. The contents of these compartments are separately emptied into a copper frying-pan, and heated over a fire, when the oil, which is thick, becomes melted, and quite fluid; then the water and dirt, or water or dirt, sink to the bottom, and the oil is poured off, leaving these adulterations in the pan, and thus showing to what extent the oil is impure. If the oil is taken the cask is hoisted on board the ship, and boiled in a large iron vessel, the oil itself floating on the top, and the impurities sinking to the bottom: the former is then drawn off, and, whilst hot, run into casks stowed in the hold of the vessel, which, when full, are carefully bunged-up, and another tier stowed, and so on till the ship is loaded.

The vessels engaged in the palm-oil trade have to remain generally for months in some river on the coast of Africa, and as all boiling, &c., goes on upon deck, the first thing done after mooring ship is to hoist her in. For this purpose the upper masts are brought on deck or sent on shore; large spars are lashed high up between the lower masts, and from these long poles are sloped down nearly to the sides of the ship in just the same way as the roof of a house is formed; across these, again, lighter poles are lashed, making a trelliswork, and over the whole mats are sewn in such a manner as to make a covering impervious to rain, and, of course, to the sun, which in the tropics is at mid-day, indeed for the greater part of the day, unbearable to Europeans. These mats are made of the pith, or rather inside fibre of a species of cane, which grows up the country. It is a most elegant and beautiful plant, growing from an immense crown after the manner of some of the Grasses, each frond or leaf varying from 10 to 18 feet or more in length, tapering from the root to the top, and having opposite pairs of lance-shaped leaflets running all up the leafstalk, the pairs being placed nearer together as they approach the apex, but at the base as much as 3 or 4 feet apart. The main rib is semi-cylindrical, and is covered with a strong silicious coat, which is stripped off, and being very durable and elastic—indeed, almost as much so as whalebone—is split into thin

slips, and when bound together is used for brooms, and by the natives for many other purposes; whilst the inside, which greatly resembles the inside of the common Rattan, though of much looser and softer fibre, is ripped into slips, and sewn together by the natives to form mats, which they use for building their huts. They are also used by Europeans, as I have mentioned above, for roofing or housing-in their ships, likewise for dunnage and various other purposes.—A SURGEON.

NEW ZEALAND VEGETATION.

A GARDENER residing amongst us here has been on a botanical excursion to our West Coast gold fields. He has just returned, and brought with him a collection of native Ferns and other specimens of plants. I send you what he wrote in one of our local newspapers:—"A portion of them are intended to be cultivated here, and the remainder to be transmitted to England in Wardian cases. Some of them are of great beauty, and comprise many specimens not hitherto classed in any botanical work on the Flora of the colony."

He describes the Mosses found on the West Coast soil as being of a very curious and interesting character—"many of the trees in the bush being so enveloped by pendent Moss, that it is difficult even for a practised eye to distinguish their species." I had the pleasure of seeing some of his specimens in a dried state at our late horticultural show, but I am not able to pronounce much about them; still, if they are really new, they will be a great acquisition for those who love Fern-growing. When they arrive in England, either dry or alive, no doubt we shall soon find out their real worth, and whether they have hitherto been "classed" in any botanical work before. I am sure that it is a fine (new) field now open for a collector from England.—WILLIAM SWALE, *Canterbury, New Zealand.*

THE INTERNATIONAL HORTICULTURAL EXHIBITION.

On the evening of May 31st this most splendid Exhibition closed, and we visited it during its last day; but we regret that we did so, for it was like listening to a harp from which some of the strings were away and others out of tune—the harmony was gone. Though the "banquet-hall" was not quite deserted, yet many were the "garlands dead." None of our "friends linked together" were there; and the few visitors adjourned at intervals into the Royal Horticultural Society's garden, and ate bread and cheese out of pocket-handkerchiefs, and drank cold toddy out of green-glass medicine-bottles. There was no intense absorbing interest in the plants as during the first days. Roses were faded; Oranges were fallen; the graceful Dacrydium was exhausted; the Pelargonium flowers were scattered, and so were those of the smaller Azaleas. The Caladiums were curled up, and some, as *C. argyrites*, dead; the Amaryllises were browned; the Orchids were nearly all carried home; and other plants were set wide and poverty-like apart to fill up vacancies.

Yet by far the larger portion of the plants were in full vigour. The larger Azaleas looked as bright as they did on the first morning; the Rhododendrons were more striking, for their noble heads of flowers were fully expanded; and the water at the foot of the rockwork was quite clear, evidencing that its turbidity at first was occasioned by the cement lining the basins being then unhardened.

It savours of cynicism to dwell as we have upon the unavoidable falling away of the beauty dependant upon short-lived flowers; but not a shade of ill will actuates our remarks—they arose simply from regret that there should be any weakening of the memories of that bright and graceful Exhibition, now a thing of the past. It was indeed a most brilliant and most successful concentration of gardeners' achievements; and in years to come, when a similar Exhibition is secured, it will be sufficient praise if truth is in the decision, "This equals the Exhibition of 1866."

One of the woodcuts which accompany our pages to-day represents a portion of the Exhibition which was decidedly the most attractive. Its foreground was occupied by the marvellous Azaleas from Mr. Turner's nursery—marvellous not only on account of their size, but of their skilful cultivation; and this foreground, flanked by the elevations crowned with tropical vegetation, by the rockwork and its Ferns, freshened and enlivened by the cascades, combined in one view fragments of each picturesque feature of the Exhibition.

The other woodcut affords a specimen of each of Mr. March's table decorations—the larger being one of the three for the dining-room, and the other of the three for the drawing-room. Such ornaments for the dining-table are confessedly the most difficult arrangements that taste has to achieve. If very dwarf they are insignificant, except to the guests beside them; if of medium height, and closely ornamented with flowers and foliage, they intercept all *vis-à-vis* communication, and destroy the effect which ought to be produced by the *tout ensemble* of the table. If tall, so that a portion of the floral decoration is above the heads of the guests, and the remainder on the level of the table, the effect of those separated portions of decoration is extraordinarily weakened. Mr. T. C. March's designs, we think, avoid all these defects. Though of medium height, the upper part is of a form not to obstruct the eye of the guest in any direction, yet the floral decoration is sufficiently raised to entirely rescue it from being considered insignificant even by the guests most distant from it.

THE DINNER-TABLE DECORATION had on the *centre* device blue and white Iris and double Narcissus, foliage of the same, and a few Ferns and variegated leaves in character. The border had small plants of Lily of the Valley and of Ferns, intermixed with Ivy. The *two side* devices, rather smaller than the centre, bore crimson and rose Rhododendrons, with buds and foliage of the same; a few variegated leaves; Virginian Creeper leaves round the top border, and some Maiden-hair Fern.

The frame of each of the devices, or epergnes, was of solid glass, and rested on a plateau of silvered glass ornamented with glass chain work, and there were three corresponding chains of glass from the top to the base.

The specimens shown were intended for a large banquet or buffet. The proportions would require to be reduced for an ordinary dinner table.

The dinner-table decoration exhibited by Mrs. Lermite, of Finchley, to which the first prize was awarded, consisted of three circles of looking-glass, having an edging of Ferns, Lycopods, and a few flowers interspersed, with a few taller fronds, and pieces of the white-variegated *Cyperus alternifolius*, standing above the rest, or hanging over the glass. The central glass, which was the largest, was arched over with white coral, partially concealed by fronds of *Adiantums* and Golden Fern. Altogether this was a tasteful and elegant arrangement, which did the exhibitor much credit.

THE DRAWING-ROOM DECORATION from Mr. March had for its flowers Lily of the Valley only, with the exception of a purple *Lælia*, with three blooms, in the centre, a few variegated stove plant leaves, and Japanese Honeysuckle twining up the stem. There was a glass rod in the centre, to which were attached three light glass chains, and the glass dish supporting the rod was placed upon a silvered glass plateau encircled with crystal beads.

THE BOUQUETS had one marked superiority over those exhibited in previous years—they were of moderate size, the largest were not much more than 6 inches in diameter. Last year they were full 9 inches in diameter, and appeared a cumbrance rather than a decoration to the bearer. In form, too, we marked an improvement. They were all more tending to the pyramidal, whereas formerly the object seemed to be to form a huge disc, more fitted to fill a tazza than to be held in the hands.

One departure from good taste, however, still prevailed, and admits of no defence—namely, bordering bouquets with blonde lace and vandyked paper. It is an offensive mingling of the natural and artificial. If a fringe to a bouquet is needed it should be slight, and of the Maiden-hair or other delicately-fronded Fern.

The Bride's Bouquet, exhibited the first day by Mr. Lucking, which won the first prize, was composed of Orange blossom, *Stephanotis*, *Gardenias*, white Roses, Lilies of the Valley, white Azaleas, white *Primulas*, Maiden-hair Fern, and Myrtle. This had faded by the second morning, and was replaced by a bouquet, the first row of which was of white *Primulas*, the second of white *Geranium*, the third of Orange blossoms, the fourth of *Stephanotis*, the pyramid completed by sprays of Lily of the Valley.

A very competent judge has furnished us with the following notes:—

"I confess being somewhat disappointed in the collection of decorative objects, as a whole, that were entered for competition at the late International Horticultural Show. Certainly there

were some good designs, and one or two now ones deserving of further improvement; still, as a whole, they did not exhibit that advance which so many of the other features of the Show presented over its contemporaries. The window-boxes offered little but what may be met with in most squares in London, the hanging-baskets were not by any means good, and the head-wreaths were confined to one set. The plant cases for drawing-rooms, however, were good; and there were some good designs for dinner and drawing-room table-decoration, the former especially being well represented, and deserving of special notice as a class.

"Excellent and meritorious as was the arrangement of the plants which constituted by far the most important feature of this remarkable Show, the same care and attention to grouping the objects here alluded to were certainly not exercised—in fact, it is not saying too much to observe that many visitors never saw them, they being arranged in the arcades at the farthest end of the Horticultural Garden, near the conservatory; and even there they were placed without that regard for general effect which was manifested in the tent. They were, however, near enough the observer to be scrutinised in detail; and a fair competition was entered into for the prizes for DINNER-TABLE DECORATIONS; and one or two departures from the original design of the Misses March showed an advance in the right direction. I must, however, first endeavour to describe those to which the prizes were awarded, and in doing so I at once admit that I cordially agree in the judgment. The first prize was awarded to a neatly dressed glass basket, the bow or handle scarcely exceeding 10 inches high, measuring from the table-cloth; but springing up by the sides of the handle were glass sprigs resembling some of those fine forms of marine production so often met with in collections of such things. This, being white, but not transparent, formed a nice groundwork on which to lay a Fern or other foliage; and in the example given only one small frond was reared against this glass hedge, and it was ample. The body of the basket was also very sparingly dressed, and that, too, with very common things; and the whole befitted either a dinner table, or, if taken singly, each of its parts might do for the drawing-room. I have said that the whole framework and its dressing were low—not exceeding a foot high at most, thereby enabling company seated at table to have an unlimited view of each other, as has been at times urged by writers in this Journal.

"The second prize was for a return to what may be called the March design of years ago, though in point of artistic merit the design fell short of it. It was a top dish elevated on an ornamental stalk, with the bottom dish divided into compartments, each containing some good specimens of fruits, as Grapes, Strawberries, &c. Valuable flowers tastefully arranged in the dressing of it gave it an imposing appearance. There was, however, a sort of intermediate stand or dish up the side of the central stalk, which might, if not carefully dressed, interfere with that important feature which it is evident the Judges wished to keep clear—that is, the line of vision.

"The third prize was given to Mr. T. C. March's design, which I hope to see again exhibited in a reduced form. A glass stalk rose perpendicularly from the centre of a circular glass mirror, and from the outer edges of this mirror glass chains connected it with the top of the central stalk. These glass chains were not by any means small and fragile, but sturdy-looking links, stouter than those of iron that are used by waggoners for yoking horses, and they, not being tight, gave a graceful and easy bend to what was in reality a brace. The outer rim of this mirror was very tastefully dressed with flowers and foliage; and a little, but very little, of these was laid against the three chains, which formed so important a part of the design, the whole requiring very little of either flowers or foliage. It was the impression of many that this design was the most meritorious one shown, and I am inclined to the same opinion; but it was much too large, and I hope to see it reduced quite one-third in all its parts.

"Following these was a design at once novel and pleasing. A central stem rose from the bottom dish; and midway up this stem branches, hooked at their ends, projected a little way on each of the three sides, on which small baskets were hung, there being a small top dish as well, but the latter, of course, fixed. The whole apparatus was of glass, and I hope to see it again, or some modification of it; unfortunately, it struck me at the time as not being very neatly dressed, otherwise it might have stood a better chance. It was, however, superior to many that were there, and as a move in the direction of furnishing

something in the way of a glass epergne, I expect to see it further improved; as it is, it may be dressed without the pendent baskets, but the latter seemed to give it importance.

"The other designs were mostly such as have been described in the reports of former shows, and with one or two exceptions were all pretty well done. One entry, however, in this department had evidently been intended for the next number (222), table plateau, as it presented a series of scrollwork, being composed of slight metal troughs, not more than 2 inches wide, and not so deep, which being clothed with flowers and foliage looked pretty well; but occupying, as it did, a space of nearly 6 feet long by 3 feet wide, its presence on the dinner table could not be tolerated. The term, however, is evidently not well understood by exhibitors, as the only entry fell short of what was considered to imply a table plateau, and I am by no means sanguine that this will ever be popular. It may be all very well to copy a fashionable flower garden, and give its details in miniature, but such things partake more of the toy than of the ornamental.

"FLOWER-STANDS for the drawing-room table were supplied by Mr. March, and to one of them the first prize was awarded. It resembled in some degree one of the prize dinner-table designs, and was tastefully supplied with flowers, not profusely as were some others which were passed by, but carefully and neatly arranged. I nevertheless think that designs for stands in this department may be yet further improved, and if manufacturers would take the hint and supply us with something that required but little dressing, they would confer a boon on those whose means are limited. I had the first-prize design for a dinner-table decoration as a step in the right direction, and trust to see others equally economically arranged with regard to the flowers required to furnish them.

"PLANT CASES for the drawing-room were shown in tolerable numbers. Here, however (especially in the prize ones), the merit of the article was more due to the manager of the plants inside than to the manufacturer; they were mostly glass cases, plain at bottom, with curved or arched tops, and might contain from 6 to 10 or more cubic feet. The plants generally employed were Ferns, Lycopods, Sedums, and the prize case had a Cactus in flower in it. Most of the cases were planted so as to show the contents on all sides, and many of them were well done, and contained excellent selections of plants; but it was evident that some had been got up for the occasion, and their good looks were not likely to continue. I would commend this branch of the ornamental department to the mechanical world, for it is evident that much improvement in the make of such stands may yet be effected, while still more may be done for window jardinets, which are as yet far from being complete.

"WINDOW BOXES were of the usual ornamental type, and appeared to be composed of Staffordshire pottery; perhaps some were enamelled slabs, and possibly others of iron. A very prettily filled box obtained the first prize, the plants being Lobelia, Geranium, Calceolaria, Mignonette, &c., all well flowered. Those from the other competitors in this class were not so well managed; the box itself in the prize one was not the best, but its contents were exquisite.

"HANGING BASKETS were badly represented, and I do not wonder at it. Plants suitable for this purpose cannot be put in at the moment and made to look well—they must under any circumstances have a few days to re-arrange their foliage; so that to look well they ought to be carried to the Show intact, which is not easily accomplished. The baskets to which a second prize was awarded were not hung, and, consequently, could not be judged of properly. There was one exquisite basket of Maiden-hair Fern, but the conditions required three. Another set was entirely filled with Dracenas, not by any means adapted to the purpose, for which, in part at least, pendent plants are indispensable.

"WEDDING BOUQUETS were rather numerous, but the make and material of one represented the many. Wedding bouquets as a whole are not showy, the absence of coloured flowers is against them. Camellias, Azaleas, Stephanotis, Roses, Orange blossom, with sprigs of Lycopodium, Ferns, and now and then Myrtle, formed the principal flowers used, not forgetting Lily of the Valley. Generally the bouquets presented the usual Mushroom shape, the flowers flat and formal, which was, however, relieved by a spray of Adiantum, or some other Fern overlying the mass. One or two exhibitors had attempted to modify the stiff Mushroom-headed outline by inserting sprigs of Spiraea japonica and other flowers of like character; but the misfortune is, that such bouquets will not bear the ordinary usage of being held horizontally

and obliquely, in which ways, as a matter of necessity, they must be held. Doubtless, it was for this reason that the prizes were awarded to bouquets of the ordinary form, as practice has found out that they endure the wear of use best. I was, however, glad to see, that the largest of these monotonous objects were passed by, and I hope to see a further reform in these monsters. Much allowance, however, must be made for these things, as the public are very jealous of any innovation, and I noticed one very nice bouquet to which no card of approbation was affixed. Its flowers and arrangement were faultless, but it had in addition a few sprigs of "Forget-me-not," which, independent of the poetic feeling attaching to the name, improved the appearance of the bouquet very much; but I suppose it was not held orthodox, and if allowed, Roses of colour, Heartsease, and many other plants alike poetical and emblematical might claim a place, so that, perhaps, it was best to exclude it.

"BOUQUETS FOR BALLS were in great force, but did not present anything remarkable in outline. I have for some time regarded these objects in much the same light as if they were made of wax or artificial work, so truly mechanical are they in their make, and when dissected it will be seen that wire forms a very important item in their construction. Generally on passing through the middle row of Covent Garden, one may see some examples of the class of bouquets here described, and quite as good. As a whole they were much too large, but the flowers were good.

"HEAD DRESSES OR WREATHS were shown only by one exhibitor, and I think such ornaments cannot well be exhibited without something else with them. The foundation of the flower-wreaths I think ought to be defined by something which the merchant of finery can enter more fully into than I can do; at the same time natural flowers as objects of ornament cannot be too strongly advocated, but let moderation guide the manufacturer. The example at the Show was certainly too bulky."

THE following is an approximation to the number of visitors to the Exhibition during the past week—viz., Monday, 16,000; Tuesday, 30,000; Wednesday, 25,000; and Thursday, 11,000.

In giving an account of an Exhibition so extensive as that which has just closed, where the subjects numbered thousands and covered acres, many omissions have occurred, and these, as well as a *resumé* of the papers read at the Botanical Congress, we purpose to supply in future Numbers.

ON Friday and Saturday last Mr. J. C. Stevens, the well-known Auctioneer of King Street, Covent Garden, held a sale of plants exhibited by Messrs. Bull, Lee, Standish, Turner, Lane, W. Paul, Fraser, Ivery & Son, Jackman & Son, Osborn, J. Verschaffelt, and others. The following are the prices realised by some of the lots:—Three specimen *Hollies* from Mr. W. Paul, £2 8s. and £2 10s.; a specimen *Taxus chesnuti* from Mr. W. Paul, £3; *Thuja gigantea* and *aurea*, £4. From Mr. Fraser, *Lea Bridge*, *Azalea Etoile de Gand*, 2½ feet by 2, and *A. Lateritia*, 4 feet by 2½, £3; *A. Perryana*, 4 feet by 2½, and *A. Lateritia*, 3½ feet by 2½, £3; *Pteroma elegans*, 4 feet by 3½, £1 11s. From Mr. Turner, Slough, *Thujopsis borealis*, £1 16s.; *Picea Nordmanniana*, £4; *Pseudolarix Kämpferi* and *Retinospora obtusa*, £3 17s. 6d. From Mr. Watson, St. Albans, *Dicksonia squarrosa*, £5; *Cyathica dealbata*, £8 10s.; *C. Smithii*, £4; *Hymenophyllum cristatum*, £5; *H. dilatatum*, £4 4s.; *H. scabrum*, £5 5s.; *H. demissum*, £5; *H. flexuosum*, £5 10s. From Messrs. Jackman & Son, *Hex dipyrrena*, 3½ feet, and *I. Watereriana*, 5 feet, £3 12s. 6d.; *Phillyrea angustifolia*, 3½ feet, and *P. ilicifolia*, 5 feet, £1 12s.; *Arbutus unedo*, 5 feet, £1 14s.; and lots of twenty-five choice *Rhododendrons* from £2 10s. to £3 5s. From Mr. Hlen, *Caladium Imperatrice Eugénie*, £12 12s. From Mr. Standish, Ascot, *Rhododendrons* Nelsoni and Prince Arthur, £5 10s.; General Cabrera and Star of England, £3 5s.; other lots of two, £1 12s. to £1 17s. From Messrs. Lane a large specimen *Azalea Alba melior*, £2 6s.; *Criterion*, 4 feet high, and *Chelsoni*, £2; two *Chelsoni*, £2 10s.; two *Madame A. Verschaffelt*, £2; standards of *Chelsoni* and *Roi Leopold*, £1 10s. each. From Mr. Jean Verschaffelt, Ghent, *Agave Ouss-elgheniana*, £2; *A. americana medio-picta*, £1 10s.; *A. univittata*, £1 12s.; *A. Schidigera*, £1; *A. coccinea*, £1 16s.; *A. filifera longifolia*, £2; *A. Ghiesbreghtii*, £2 2s.; *A. species jalapa*, £2 4s.; *A. filifera*, £1 10s.; *A. chloracantha*, £1 5s.; *A. americana fol. var.*, £1 10s.; *A. Xalapensis*, £1 5s.; *A. virginica*, £2; *A. stenophylla*, £2; *Dasylirium serratum*, £1 10s.; *Bonaparteae gracilis*, £1 10s.;

a fine specimen *Yucca aloifolia variegata*, £2 8s. From Messrs. Ivery & Son, *Azalea petuniæflora*, £3; *Empress Eugénie* and *Madame Michel*, £2 each.

GARDENING PROGRESS IN NEW ZEALAND.

To the French settlers of Akaroa we, the residents in Canterbury, are indebted for the introduction of *Salix babylonica* in 1840. Upon their way from France they put into the island of St. Helena for the purpose of testifying their veneration for the memory of Napoleon Buonaparte, and they brought thence some cuttings of the Weeping Willow. We now have very large Weeping Willow trees on the plains, and find their shade very agreeable during the oppressive heat we experience at the present time; thermometer in the shade 88°, and in the sun 118°, hotter than ever previously known in Christchurch within the memory of "that extraordinary individual" the oldest inhabitant. On the 9th of January, at 12 p.m., the thermometer stood at 83° in the shade.

Akaroa, by us of the plains, is called, on account of its near approach to the sea, its beautiful climate, and beautiful woodland scenery—"our Brighton." Its romantic scenery is beyond description, and it is considered to be very salubrious for sick invalids.

We are now raising seedling *Rhododendrons* by the thousand, but it is only recently that we have been successful, after repeated trials year after year of imported seed. At last, I am happy to state, we have succeeded in obtaining seedlings an inch high, and others far beyond the seed-leaf. I look upon these seedlings as a great boon to Canterbury at large; they will, no doubt, in course of time be sold like the Oak, Ash, and Elm by the thousand, instead of one solitary plant of the common *R. ponticum* for 5s. as at present. This is a very unfavourable climate for the germinating of small seeds like those of the *Rhododendron* family, owing to the continued power and intensity of the solar rays during summer. Evaporation from the soil is so susceptible of change that it almost baffles the skill of man here to retain a uniform moisture for seedlings.

—WILLIAM SWALE, *Avonside Botanic Garden, New Zealand.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

LET the gravel walks be occasionally gone over with the weeding-knife, and keep them constantly rolled; the best time is after rain, when they are dry enough to bear the roller. Detached leaves from Cabbage-beds in bearing to be removed to some vacant quarter to be trenched in, and not left to wither and rot amongst growing crops, forming a harbour for slugs and other vermin. Every spare piece of ground should be now trenched up in readiness for planting early Savoys and Brussels Sprouts. *Beet*, the full crops to be thinned out to about 9 inches apart. Bear in mind our former remarks on transplanting, if vacancies occur. *Broccoli*, a few drills of Cape may be sown in light rich ground, to be thinned out and kept standing. *Cucumbers*, thin out the young seedlings on ridges, and see that the transplanted ones do not want for water. Tilt the glasses for the admission of air, and shut down close in the evening. *Cauliflowers*, liberal applications of liquid manure must be given to them, if you would have them fine. *Celery*, prick out the late-sown, and keep the young advancing crops well supplied with water. Prepare the trenches, and, when fit, lift the plants with a good ball of earth, and plant them at a foot apart, using a trowel or small fork in preference to a dibble. Give a liberal application of water, and after they have started into growth plenty of liquid manure poured on the soil from the spout of a watering-pot without the rose. If from drought the tops want refreshing, a sprinkling of pure water is best. *Lettuce*, continue at regular and short intervals to tie them up for blanching, and thin out all advancing crops of the Cabbage varieties, which are always best left to perfect themselves where sown, and if small sowings are kept up at short intervals transplanting will be superfluous. *Peas* and *Beans*, continue to keep the surface well forked amongst the growing crops; this is at all times attended with the most beneficial results, as it increases their productiveness, and, by keeping them in a vigorous growing state, assists greatly in warding off the injurious effects of mildew, which often attacks the later-sown ones. Pulverising the soil, besides exposing it more to atmospheric influences, greatly assists in retaining moisture under the roots during dry weather, and drought,

together with hardness of surface, is, in our opinion, favourable to the production of mildew. If this begin to show itself, a very weak solution of salt and water sprinkled over the tops will keep it in check. Turnips, continue to make successional sowings, and dress both these and other crops likely to be infested with the fly with charcoal dust when they are in a wet state. Keep up successional sowings of Radishes, Lettuces, and salads, which require to be sown often now, in quantities proportioned to the demand; the north side of a sloping bank is the best situation for these sowings. Vegetable Marrows on ridges to be treated as advised for Cucumbers.

FRUIT GARDEN.

Great activity is necessary in this department, as the rapid growth of the trees will require constant attention in stopping, removing superfluous shoots, and nailing in. Peaches may now have their final disbudding; let every shoot not required be removed with a sharp knife, and nail in the remainder carefully; if any of the extreme shoots are growing out of bounds, they may be stopped within a few eyes of the base in order to preserve the fruit, but take care to train up another shoot to succeed. Apricots to be thinned. Keep the lateral shoots of Vines closely stopped at the first joint. We do not approve of the practice of removing them entirely. By retaining the joint we preserve them for whatever purpose they may serve in the economy of the Vine. We should always endeavour to assist the operations of Nature, as well as judiciously check over-luxuriance, and in this respect we know of no tree more tractable than the Vine.

FLOWER GARDEN.

The directions given for the past two weeks are still applicable to operations going on here, and which should be brought to a close this week. Persevere till every vacant bed is tilled. Summer climbers will now be in fine condition for planting out, if directions as regards growing, potting, and staking have been attended to. See that they are properly secured from high winds as soon as the operation of planting is finished. Heliotropes and tender annuals may now be planted out with safety. Choose the warmest and best-protected parts of the flower garden for these tender things. As soon as the beds are all filled and finished off, plant out in the flower-borders the odds and ends which are left. Attend to the staking of Carnations, Picotees, and Pinks as they grow; this will greatly improve their appearance when in bloom. Put in large quantities of different varieties of double Wallflowers in rows behind a north wall or hedge. Alyssums, Iberises, and similar plants should be increased by cuttings for another season. Cut the old plants back as soon as they have done flowering, and they may remain among some of the grouping plants in the borders during the summer months.

GREENHOUSE AND CONSERVATORY.

The turning out of house plants is a proceeding which requires some forethought. Although it may not be desirable to turn out some of the tribes so early in the season on their own account, it is at least so in many garden establishments in the country, in order to carry out without impediment the forcing of fruits and other matters necessary for the supply of a family. In this respect country gardens differ much from the gardens around the metropolis. In the latter, display is the principal point; in the former, display, although not unheeded, is sometimes obliged to give way to more substantial matters. The first step is to provide a proper situation, and one, scarcely secondary, is to secure a good sound bottom on which to place the pots. When the least suspicion of water-lodgements exist drainage should in the first place be secured, and the pots be elevated above the ground level. We do not mean to assert that house plants must be turned out, we are merely advising it on the score of expediency. Plunging, we should say, should in most cases be resorted to, provided the plunging material is above the ground level. All plants with fine hair-like roots, as the Ericas and Epacrises, should certainly either be plunged or double-potted—that is, inserted within an empty pot. Another great point is to classify the plants with regard to their general habits and character. No plant-cultivator would think of mixing Heaths with Pelargoniums or Cacti. After the bedding-out is accomplished a reserved stock should be immediately taken in hand, and should receive high cultivation in order to fill up blanks the moment they occur either in the houses or in the borders. Some of the hardier stock in the conservatory, such as hybrid Rhododendrons, Camellias forming buds, and Orange trees in tubs or pots, may soon be set out of doors. This will give more room to the plants which must

remain either on account of their tenderness or the display which they make. A sheltered spot should be selected out of doors, but by no means under the drip of trees. A temporary awning, but of a very thin character, should be suspended over them for a week or two at first. All young or other stock growing forward for specimens of high cultivation must now have much room. Make it a rule to let no two specimens touch. Very young stock of Ericas, Epacrises, or small fancy New Holland plants will be best in a pit or frame, placing the lights to the north. Pinch off the decaying blossom of hybrid Rhododendrons; give liquid manure, and if wanted for early work endeavour to force them slightly into wood. Get some young Thunbergias put into their final pots for trellising; these are useful, and keep up a late display. Look to the runners of the tree Violet, also the Neapolitan, and do not delay any longer with the Chrysanthemums.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

NEVER was better weather for the keeping down and cutting up weeds, and, therefore, took the opportunity to run the Dutch hoe through all growing crops, as even if the weeds are scarcely to be seen, they would soon show themselves if a showery day or two were to come. The bright sun and the cold nights, with east and north winds, are very trying to many things. Corn fields, as yet, look well; but grass grows but slowly, and some of the tender points on our lawn are browned as if frosted. On Wednesday morning early, in a shallow earthenware vessel there was ice one-sixteenth of an inch in thickness.

Watered lots of Peas and garden Beans in tiles and boxes, for transplanting. Sowed several rows for succession, as pheasants are not now so keen after them. Removed a row of Tom Thumb from the orchard-house, where they had done good service, and would have done more, only there was plenty to succeed them. Dillistone's Early bears well under a glass case without any artificial heat; Sangster's does not do well for that purpose, but taken all in all, though not the earliest, it is the most profitable early Pea we have. Watered with sewage water Cauldlowers, Peas, Beans, &c., and pricked out young Cauldlowers. The fresh quarter, turned out eight days ago, was watered with clean water. Giving rich nourishment to such young plants is very injurious. Gave sewage water to a bank of Lettuces, to keep them from running prematurely. We use the sewage for these purposes, not only because we like it best, but also because it husbands so far our clear water, of which we have a fair supply as yet; but in this neighbourhood it is becoming scarce, and some are purchasing it at so much a-pail.

We have never had the fly worse on early Turnips; and as for Radishes, unless carefully netted, and the net kept far enough every way from the seeds, we would never see one. At less than a mile distant, cottagers can throw a dusting of seed into the ground, and every seed will produce a seedling. Here it is a constant contest with the birds, and they too often conquer at length, and obtain more than the lion's share. Pricked out lots of Celery of different sowings, the first being now strong plants, which we shall finally turn out as soon as there shall be a change in the weather.

Sowed Onions for salads, Spinach for succession; filled the vacancies in seed-beds of wintergreens, and would prick out some if we could find time. Dug up a good portion of the Broccoli stumps; this crop, though planted between Peas, and rather late, has done wonders, chiefly owing to giving it plenty of sewage water, until the long nights of last autumn came.

Pricked out young Cabbages, cleared away all the covering material from Sea-kale, and sent in the last dish; it will want all the summer now to grow. Pulled Rhubarb for preserving; the huge stalks would be better of a sewage-watering at the stools. That, and rich soil, will make it grow almost any size, and, unlike some other things, large stalks are tender enough, if from dryness and age they do not become too hard.

Potatoes that had been protected with old sashes are throwing their tubers quite near enough the surface. Instinct might have told them to go down after moisture in this parching weather; but as we cannot do anything in the way of earthing-up, as they are now so thick, and formerly had early Lettuces between the rows, we will water the beds over if we do not have rain soon, and then will cover the ground slightly with half-rotten leaves to keep the moisture in and to keep the light

of the sun from the tubers near the surface. A Potato at all greened, however useful for other purposes, is of small account when cooked. Hoed well between the earliest out of doors, and will earth-up or not earth-up afterwards, according as the tubers are apt to come or not to come to the surface. When planted in nice friable soil from 6 to 8 inches deep, earthing-up in general may be dispensed with. North borders, or the north side of sloping banks, will now be useful for Turnips, Radishes, and Lettuces, and a little Endive may be sown for those who like it early. Most people will care nothing about it so long as they can obtain good Lettuces; and these, too, always seem best in hot weather.

Cucumbers.—The parching weather has brought the green fly into our frames, and to this result no doubt a coolness at the roots has also contributed. We have, therefore, used tobacco paper for smoking them, and applied a lining to the front of the beds, and merely backed up against the boards behind. We intended giving this lining two or three weeks ago, but could not get at it, but we believe a little more heat to these shallow beds would have done much towards keeping the fly away, and here, as in most things, prevention is better than cure. We seldom use such linings for throwing heat into the bed at so early a period; but this season our beds were made much more shallow than usual, and a cold bottom with such a bright sun does not suit Cucumbers or Melons at this season. Took off cuttings of desirable kinds, and from plants quite clean, as these cuttings will fruit earlier than seedlings, and will do very well for summer and autumn work. We do not like plants from cuttings for standing the winter. Seedlings seem to have more stamina for contending with the dark days. Plants for ridges, Gherkins, Vegetable Marrows, &c., we have turned into rather large pots, under protection, as the place intended for them is not yet ready. We have never had them better than on a bank sloping to the south, and without any thing like a hotbed beneath them; but the soil was turned over after every sunny day, so as to turn the hottest soil down, and the plants were planted out in this heated, aired soil, in the first or second week in June.

FRUIT GARDEN.

Strawberries.—Hoed the Strawberry ground pretty deeply with the Dutch hoe, not only to destroy weeds, however small, but to fill all cracks and fissures produced by the dry heat in stiffish loamy soils. Followed with a good watering of house sewage, which will be farther washed in by the first rains. Noticed that previously to the watering the pollen dust was becoming poor and scanty, and setting was taking place but slowly; but after the watering the footstalks looked up more boldly. To enjoy a Strawberry it should be picked clean with clean hands, and be touched only by the stalk. To keep the fruit clean nothing is better than clean wheaten straw laid along each side of the row. Grass, if at all long, answers very well. We often use common litter from the stables, from which most of the droppings have been shaken. This, if applied early enough, will, in general, be washed clean by the rains before the fruit ripens. Spent hops and fresh tan are also good for the purpose, as it is but seldom that the tan is so fine as to rest on the fruit, and both hops and tan are generally disagreeable to slugs, snails, &c. Failing these, boards laid along the sides of the rows are very good—better than tiles or slates; and failing all such conveniences, if the plants are in rows, a string of small cord stretched on each side and twisted round a stick every 6 feet or so, will answer very well for keeping the fruit from the earth.

Some years ago we noticed a basket of nice Strawberries exposed thinly to be dried in the sun. They had been mud-enersted by a thunder shower, had been washed in a pail, and were then preparing for the table. They looked better than could have been expected, but who could have eaten them with satisfaction if the treatment they had passed through had been known? In fact, the general system adopted for sending Strawberries to table wants a complete overhauling. It matters not how carefully the gardener may pick them by the stalk, not touching a berry with his hands, however clean they may be, instead of being sent in a basket, or just turned over on an elegant dish—and they never look better than when so done—they must be built into cones and pyramids and miniature-shaped haystacks, each berry being taken once or twice between the fingers to get it into the proper shape and form, making sure of a good deal of handling and touching, as if absolutely necessary preliminaries to the future eating and digesting. The time will come when those who grow and

gather fruit will also dish it and send it to table. A word to the wise ought to be enough. Lately we tried to show that the grower of fruit should be the gatherer, directly, or by his assistants, and stated good reasons why; but the good rule is, perhaps, more broken than observed, causing unpleasantness to many and benefit to none.

The young plants raised from the border, and planted out under frames, have set freely and are swelling fruit fast. We have now removed two out of the four rows in the Peach-house, and will take out another in ten days. On two or three of the plants removed there were traces of red spider, so that they were not moved at all too soon. The fruit has swelled very fast under glass lately, even without any artificial heat. Without bright sun the mere glass covering accelerates the ripening but little. The pit in which British Queens are ripening and swelling had a good washing against the back and end walls with sulphur and lime, and a little soot to tone down the colour.

In the orchard-house observed some fly on two or three small plants, and had them carefully washed with quassia water. The trees have had rather heavy syringings every afternoon in this hot weather, and to save watering we shall top-dress all the pots with a rough mixture of mushroom dung from an old bed, and fresher horse-droppings that have lain and heated long enough to kill the ants that might be in them. These materials had a little soot and lime mixed with them before being used for top-dressing the pots. The water question alone would make us seriously think of giving up fruit-tree culture in pots. Thinned a lot of the Peach trees of fruit, which comes in for tarts, &c., but no use can be made of Nectarines in the kitchen when in such a young state. In the Peach-house watered the Strawberries, and frequently twice a-day; in fact, watering and syringing have been our chief work of late, merely to keep things from going back with us. Syringed all the trees freely night and morning, except where the fruit was ripening. The house being about 50 feet in length, would be too long for a single comfortable establishment, as too many fruit would be apt to come in at a time. Our heating-pipes are badly placed, but they answer well in this respect, as the fruit near them comes in first, and long before those on the back wall, so that out of this house we have gathered for from ten to fourteen weeks. In general, however, smaller houses, or a range with divisions, are most suitable for moderate establishments. In addition to the syringing we gave the borders inside and outside a good watering with drainings from the farmyard manure. Though rather admirers of house sewage for common crops, we dislike to employ it much in close places under glass. A good watering when the fruit is swelling fast helps it very much, but it is as well not to soak all the ground occupied by the roots at once. We watered our border at three times, with an interval of from four to six days between each watering. Owing to this precaution we rarely have a fruit thrown off, even though self-preservation would often tempt the trees to do so, when very heavy crops are left.

Vineries.—Went over them in a dull morning and evening, nipping out a few more berries, and reducing laterals in the earliest house, which will succeed the little pit now nearly over; regulating shoots in the late vinery, and bringing the bunches coming into bloom down more into the house, and away from the glass to which they have a tendency to rise. Gave the earliest of these houses a little warmed water, the border being still covered with old sashes, and bedding plants beneath them. Gave the late vinery border a watering from a cistern in the open air, where the water had become warmed by several days' sun, a peck of superphosphate having been previously scattered over the border. In the earliest house, the Sweetwater Grapes were beginning to become transparent; we will now leave a little air on all night, say half an inch in two or three sashes at the top of the house. By-and-by we shall treat the second house in the same way. The late cool vinery we are now keeping the closest and the warmest, and will continue to do so until the fruit be set. Those at the top of the house are beginning to set freely. No moisture will be given except that from the watering of plants and the syringing of the pathways. Even in setting in such smy weather, it is well not to have the atmosphere too dry, as it binds the capsule too tightly round the parts of fructification. A good temperature, with an atmosphere moist enough, will also help to draw out the bunch, so that the berries shall not be so densely clustered together. We often think that if many Vines had more of the habit of the Muscat, what a fine time we should

have in thinning. Often when not operated on, when the young fruit are not larger than bird shot, it is next to impossible to get the scissors into the bunch of close-setting kinds without injuring the berries that are left. Two things in thinning Grapes ought always to be avoided: First, using scissors after the points have become dirty or discoloured with the Vine juice, as the marks are so apt to be left—it is easy to keep them dry and clean; and the second is, to avoid oiled hair, or hair of any kind, or dirty hands, or clothes saturated with perspiration, coming in contact with the bunch. In thinning, those with moist hands should catch the bunch with a neat hooked stick or clean wire; but a stick is the better of the two. For air-giving, temperature, &c., see last and previous week's notices.

Fig-pit.—*Figs in Pots.*—Gave the trees a good watering with manure water, and syringed the tops frequently before shutting-up, about 4 P.M., so as to obtain a good amount of sun heat. This shutting-up in a moist atmosphere involves the necessity of giving air early in the morning, so that the fruit swelling fast may become dried, as, if the damp hang long on them, a spot will be formed at the point, and from thence it will spread and rot, instead of the fruit swelling and ripening. In dull weather, after such bright sunshine, there will be a necessity of having fire heat in early houses to permit of more air being given to neutralise this tendency towards damping. Except when the trees are in a state of rest, it is hardly possible to overdo Fig trees with moisture if the drainage is all right. Stagnant moisture is just as bad for throwing off a crop as great dryness; and let it not be forgotten, that whether growing in a pot or in a border, if the roots be too dry, they must not be saturated at once, but by degrees, say in four or five days' time. We have seen young trees well loaded throw off their crop from dryness; we have seen similar trees cast their crop when a copious watering was at once given. The stimulus was all right enough for growth, but it was more than the young fruit were prepared for, and off they dropped. It is the safest plan to have the soil rather moist before the buds swell much.

We must commence as soon as possible on the trees out of doors, which are showing plenty of fruit. We have merely stopped the terminal bud of the shoots showing fruit.

ORNAMENTAL DEPARTMENT.

Doing a good deal in the way of potting Balsams, Feathered Cockseeds, Geraniums, watering, and keeping plant-houses moist and shaded to save watering, even if not quite so good for the plants. Winter-flowering Heath, Epacris, &c., should now have a cold pit, to be kept rather close until growth is made, and then be hardened off to ripen the shoots. Camellias and Azaleas done blooming and allowed to stand a week or two after being trimmed, should have a close, warm, moist atmosphere to encourage growth, and that will also do much to check insects, the plants being gradually hardened off as the flower-buds are formed. Many of the hardier plants, as Cytisus, Acacias, &c., will stand in a sheltered place out of doors, where no other place can be given them. We were forced against our will to smoke Caladiums, on which we never saw green fly before. Gloxinias in bloom should have a shady place, as but little sun spoils the delicate blossoms. Dahlias we must divide, for we are behind, having kept them in a cool place, and they are just moving. The frosty mornings have rather frightened us from bedding-out; but if we did not make a commencement we should never finish, and therefore we have begun, and most likely some thousands will be out before this appear in print. One reason why we do not hurry is, that most of our plants are growing now, planted out, in earth pits, Celery trenches, &c., so that they are not confined as if they stood in little pots. One chief object, however, in so treating them was to avoid the necessity of watering them often. Many beds have only been watered once since the plants were turned out in the beginning of April. Most of them lift well now for planting, and we generally carry them in little boxes, and this saves the ball of earth about the roots. The system would not answer so well where the plants must be carried some distance from the earth pit to the flower garden. Under such circumstances pots and boxes, where the roots are kept near at home, are best; but the keeping of thousands of plants in small pots is a serious matter, even as respects watering, where labour is rather scarce.—R. F.

CABBAGE AND DITTO.—"I love you like anything," said a young gardener to his sweetheart, pressing her hand. "Ditto," said she, returning the pressure. The ardent lover, who was

no scholar, was sorely puzzled to understand the meaning of "ditto." The next day, being at work with his father, he said, "Father, what is the meaning of ditto?" "Why," said the old man, "this here is one cabbage-head, and that ere's ditto." "Drat it!" ejaculated the indignant son, "then she called me a cabbage-head!"

COVENT GARDEN MARKET.—JUNE 2.

A WEEK'S fine sunny weather has greatly improved our supplies, both home-grown and otherwise, and the French fruit generally has been better. Prices have accordingly receded, and we may look for a greater reduction in the course of the week. Some open-air Strawberries have come to hand, and Green Peas in considerable quantities from Kent and the west of England.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once

N.B.—Many questions must remain unanswered until next week.

BOOKS (*Natural J. S. T.*)—We do not know whether you require books descriptive of Ferns, nor whether in botany you seek the elements of the science. You must be much more explicit.

HERBACEOUS CALCEOLARIAS (*B. N. R.*)—Your seedling Calceolarias are the very best we have ever seen, size, form, and colour being excellent. There is not an inferior flower among them. The bright spotted yellows and the dark browns, both spotted and striped, are first-rate. Had you exhibited them at the International Horticultural Exhibition, we venture to say that you would have had innumerable applications for seed. Pray inform us when you are prepared to send out packets of the seed of these splendid flowers.

PEAR TREE LEAVES BLISTERED (*An Irish Subscriber*).—The leaves have that blistered and distorted appearance caused, we think, by the sap vessels bursting through exposure to cold or frost. This condition is very common in the present season, and the leaves so affected are much infested with green aphid. In some instances mildew has also already shown itself on the blistered part. A good washing in the afternoon with a solution of 1 oz. of soft soap to a gallon of water is the best remedy for the fly or aphid, applying it forcibly with a syringe or garden engine every second day. Dusting the leaves with sulphur whilst wet will destroy the mildew.

AMMONIA WATER IN VINERY (*Idem*).—We recommend keeping the troughs full of liquid manure, or guano water of the strength of 2 ozs. to the gallon, from the time the berries have set up to their changing colour for ripening, but we do not recommend manure water formed of other substances containing ammonia, except soot.

INTERNATIONAL HORTICULTURAL EXHIBITION.—The third prize for six standard Roses (Class 115) was not awarded to Messrs. Paul and Son, as stated at page 391, but for the following varieties:—Adam, Paul Ricaut, Madame St. Joseph, Anna Alexieff, Gloire de Dijon, and Jules Margottin, exhibited by William Earley, gardener to F. Pryor, Esq., Digswell, Welwyn.

SEEDLING TULIPS (H. H. H.).—Your Tulips are large in size and bright in colour, but there is a coarseness about them which is a decided objection. There are many bright-coloured varieties of Tulips imported every year, which are equally effective and much more perfect in form.

PEACH TREE LEAVES FALLING (Introus).—The leaf sent is certainly perforated by some insect, but such perforations would not cause the leaves to fall. The leaf sent was very thin, and would seem to have been formed in a close moist atmosphere, and if you had not stated that the trees were well attended to, we should have said that the leaves fell in consequence of want of water. Have you been using any solution to free the trees of insects? If not, then we think the fault rests with the roots. If the trees have been neglected in respect to water, then well watering them now will not keep on leaves like that sent. It was ripe.

KEENS' SEEDLING STRAWBERRY BARREN (J. Mackenzie).—Allowing the plants to grow too close may have made them barren, or the soil may be too rich. If you thin out the plants so that they may be 18 inches or 2 feet apart every way, and keep all runners cut off as they appear, we have no doubt your fine plants will have by autumn very fine well-ripened crowns, calculated to produce a good crop another year. We find that most of the plants in our beds of Keens' Seedling have this year gone off in consequence of canker, and though those which remained have shown well for bloom they have failed in throwing up the trusses well, and the flowers are very imperfect. We have some beds in another garden about two miles off, and the plants are there remarkably healthy, and promise an abundant crop. We think that our Strawberry plantations have been injured by the late frosts, especially those of Keens' Seedling and British Queen. Black Prince and La Constante are fine, but the first two will be next to failures.

MULBERRY PROPAGATION (A. B.).—The cuttings are best selected from the bearing wood, for the trees thus obtained fruit when much smaller than those propagated from any other part of the tree. The cuttings should be taken from the wood of the previous year in the same manner as for Currants and Gooseberries, and may be 6 or 8 inches in length, cutting them transversely below the lowest joint or eye. Insert them about 4 inches, or two-thirds of their length, into the soil. They require to be put in early in spring, the end of February or beginning of March being a good time. A good, rich, and rather light soil is all that is required. If two or three shoots appear, rub off two and leave the strongest if you wish for standards; for bushes leave all the shoots and stop them; and for fan-trained trees for walls or espaliers if two shoots are produced disbud to one, and cut it back in the following season, but if three buds grow retain one as a leader, and train the others right and left. The Mulberry may also be increased by layers, in which way trees may be obtained of a larger size than by cuttings. It may also be raised from seed.

PANSIES DETERIORATING AND CHANGING COLOUR (C. R. H.).—We think that the Pansies have deteriorated from long continuance in the same place, and that neglecting to take cuttings and make fresh plantations has caused them to change colour. The late dry and cold weather has been unfavourable to Pansies, and unless well watered in such weather, the blooms soon fade or ruin. You are correct in saying "that to have Pansies up to the mark in size, colour, and shape, it is necessary to take cuttings annually, and to throw away the old plants, making new beds in a different place." Pansies like a good, rich, and rather strong soil, with good drainage, and abundant supplies of water when in flower. The soil required should be deeply and well worked. No blooms came in the letter.

DISEASED CUCUMBERS (W. S. C.).—Gardeners call the disease which affects your Cucumbers "gumming." The cause is obscure, but a remedy is using for the soil in which the plants are grown a rather poor loam, such as the surface of a pasture after the turf has been removed, and trusting to top-dressing and liquid manure for nourishing the plants. This is the plan recommended by Mr. Fish.

GREENHOUSE MANAGEMENT (Miss E. J.).—Keane's "In-door Gardening" is the work you probably refer to. It contains what you mention, and can be had free by post from our office if you enclose twenty postage stamps with your direction, stating the name of the book.

SPOTTED LEAVES (Rustic).—Watering the trees in your orchard-house daily, and then suddenly reducing the watering to once a week, is the probable cause of the black spots. The supply of sap must have been extraordinarily changed by such a transition. When you reduced the watering it should have been gradually, and the surface over the roots should have been mulched.

FIGS' STONING (Bang).—You are rightly informed. The nuts should not be gathered until fully ripe, should not be taken out of the husks, and should be placed in stone jars having lids, burying the jars in sand in a cellar. They keep firm for a long time, but they shrivel considerably if kept in a cupboard. If the cellar is damp, it will suffice if the nuts are put in stone jars, and the jars buried to the rim in sand.

FRUIT STONING (Item).—The difficulty in keeping fruit is a suitable place, and knowing the kinds, for many decay because their season is past. The floor of the store-room would do for Apples, placing them on clean wheat straw, and covering them with a thin layer of the same. We presume that the store-room is not heated, that it is not wet, that frost can be kept out, and that air can be given. If it offers these conditions, then it will do for Apples, but if very dry it will not suit them; for, though keeping well in such a place, they will be apt to shrivel, and it is desirable to have them firm, crisp, and juicy. The fruit must not be laid thickly or in heaps, but should, on gathering, be spread out thinly for a few days. Afterwards they should be carefully stored away in single layers, keeping them from light either by having shutters to the windows, or covering with a thin layer of dry clean straw. It is not necessary to turn the fruit, for the handling in doing so causes bruises, and the Apples rot; but it is desirable to have them so laid thinly that they can be examined, and those which are decayed picked out. Apples will do well enough in this way, but Pears require a drier place, and do not keep at all well where Apples will do so. They require more care, and for them shelves of some non-resinous wood are required, as Elm, Beech, &c. Deal gives a taint of turpentine to the fruit. In your store-room you may have Pears on the shelves, nailing a strip of wood, 2 inches deep, on the edge, and placing on the shelf an inch of sand dried in an oven. The fruit should be gathered on a dry day, and with great care, so as to prevent bruising. It should be laid on the shelves for a few days before being finally stored away, and the room should be opened on fine dry days. The Pears will part with some moisture, and in ten days or a fortnight should be placed very carefully in a single layer on their sides on the sand; they will thus rest more easily than if laid on the bare wood. This mode of treatment will do for those that are not expected to keep long, but the late kinds should be covered with dry sand. On dry days air may be admitted to dispel damp, if the room be at all damp; otherwise keep it close and dark, and go over the fruit occasionally in order to remove any that may be decaying. Avoid handling the Pears to ascertain when they will be ripe, for that can be much better determined by their changing colour, and immediately they are fit for table commence to use them, for no fruit will keep for any length of time afterwards. In frosty weather, the windows should be covered with some protecting material. We fear, from your having no fruit at Christmas, that your Apples and Pears are early autumn kinds, as many of the autumn kinds will keep till Christmas, when the winter fruits come in. Surely you have Apples that will keep over Christmas. We had Pears this year in April and Apples in May, and yet we thought they ought to have kept longer.

MR. NEWTON'S MODELS.—Mr. Newton has written to us as follows:—"I desire to correct an error in your report of my exhibition of models in the International Horticultural Exhibition. You state that no one was there to explain them, and that that was the reason the Jurors did not seem to appreciate them. I had an attendant there from the opening of the Exhibition, and he attended there every day, to explain the working of my models for warming and ventilating by warm air in connection with hot-water pipes, &c.; also to explain the collection of working plans for laying out grounds to scale, which I have exhibited. I am the only landscape gardener who has exhibited plans at the International Horticultural Exhibition without competing for prizes, and although entered in the catalogue, no notice was taken of them."

HEAVY MARLY SOIL (Julia M.).—To render it fitter for a garden, we would remove the surface soil, and burn 9 inches in depth of the subsoil of the whole space. Mix the burnt earth with the removed surface soil, spread it over the entire area, and manure as needed.

IRISH PLANTS (G. Smith).—The "Bell Heather" you enclosed is usually called *Menziesia polifolia*, or Irish Worts. The shrub is *Juniperus saxatilis*, or common Savin. They are not marketable, nor is *Osmunda regalis*.

ONION (K. O. T.).—The Onion which you received from Brussels under the name of *Onion jaune plat* we think is the Welsh Onion (*Allium fistulosum*). At least, in its present state it entirely corresponds with that kind.

NAMES OF PLANTS (K. O. F.).—You must send better specimens of the coniferous plants. It is almost impossible to identify small scraps, and to do so costs more time than we can afford. (*Bar-kol*).—1, *Bellis perennis*, destitute of ray florets; 2, *Euphorbia platyphyla*. (*Cottford House, Sidmouth*).—*Cheilanthes fragrans*; *Aristolelia Menquii*. (*John Riddell*). *Amygdalus nana*; *Polypodium scolopend.* (*C. C.*).—*Aotus gracillimas*. (*T. E. Drake*).—1, *Polystichum aculeatum*; and 2, *Cystopteris fragilis*, as nearly as we can tell from the very young fronds sent.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 2nd.

DATE.	THERMOMETER.						Wind.	Rain in inches.	GENERAL REMARKS.
	BAROMETER.		Air.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

MY HAMBURGH CHICKENS.

It has often been remarked by foreigners, that Englishmen are always talking about the weather, the said foreigners implying, perhaps, by this remark, that we have nothing else to talk about. I hold that this is not true in the least degree; we have many things to talk about; but why should we not talk about the weather? It is always changing, so that weather news is often the latest news, and it is good manners to speak about the most recent intelligence—nay, instructive too. I intend, then, to talk about the weather as long as I live, unless the climate alter and we have six months winter and then six months summer, when, save twice a-year, there would be no weather news at all. Well, we have now beautiful spring weather with us, though frosts at night somewhat retard the progress of vegetation. However, let that pass; the days are lovely, so we will be content. Now, do the good people in Madeira or Italy, who have continuous settled weather, enjoy a fine day as much as we do, to whom it is but a passing guest? I doubt if they do. So give me for this and a thousand other reasons showery, changeable, chilly England. Oh, the intense delight that a warm spring day affords me! The east wind gone at last, and again I dare to stroll; again the sun warms me as I walk leisurely, very leisurely, among my roses, picking the grubs out of the delicate rolled-up leaves. I regard a rose grub, or caterpillar, of whatever colour, a monster of no ordinary kind—a very fiend, a Satan in Paradise. My roses! I like to have a specimen glass on either side of me as I write, with, say, a Charles Lefebvre in one, and a Senateur Vaisse in the other, or a Cloth of Gold and a Jules Margottin—and these beauties attacked by grubs! But to return to the weather subject, and the intense pleasure given to us this glorious springtide. I hear again the soft twitter of the little birds, the cawing of the rooks. There, yes, there is the blackcap back again in the shrubberies near me, and I hear the cheery note of the linnet just beyond my hedge. But not alone is the ear filled with delights. There is the world of eye as well as ear. Oh, the delicate green of the hedges, the stately horse chestnuts with their fan-like leaves and candelabra-like blossoms! Then there is the brown-green of the half-opened oak leaves; but I saw a rarer sight to-day—it was a walnut tree of many years' growth, consequently of great size, the half-opened leaves abundant and of a darker brown, far darker than that of the oak, and two finer elms stood behind it; and how the two varieties of trees showed off the beauty of each other! Much pleasure may be had from watching varieties of foliage. Thus my walnut will presently delight me from the yellow tint of its leaves. Every tree has blossomed well here—crabs in this part one mass of bloom; apple trees with leaves hidden by blossom. Everything is looking spring-like except a wicked-looking old ash at the back of my church, which does not yet show a leaf. Why should not the ash be exterminated where better trees will grow?

But what about my chickens? Why it was on my way to visit them that I made all these remarks to myself. But for those Hamburg chickens of mine, I should not have got up from my desk while in the middle of my next Sunday's sermon. An old clergyman fond of his garden used to say, "I thin my Grapes between the heads of my sermon." Can you not fancy him doing it?—the deeper the subject, the deeper would go the scissors. Well, I like to have a stroll among my chickens when the text is awkward to handle. But I ask myself, Why do I take such pleasure in chickens year after year? "Wretched little half-clad birds," says one who only likes chickens nicely browned, or white and soft, with a pink tongue between them. Scoffer! thou art ignorant on the subject, so be silent. But I have not answered my own question, let me try to answer it.

My pleasure has nothing to do with exhibition ambition, for I never exhibit. Perhaps there is something in it of habit and association, for I think of past years; but I think there is more from the pleasure which looking at young things always gives us. Thus, take the case of a boy going out in life for the first time. How kind eyes watch him with interest, and moist eyes look on him—not of relatives only and near friends, when he bids good-bye, and is away into the great world. Yes, it is the youth, the fact of youth and the hopes connected with youth, that charm us. We were once young,

we had high hopes. But, then, how uninteresting I fear we middle-aged folks must be. There is poetry in the youthful locks, and in the silver beard; but only very plain prose in the grizzled or semi-bald head. And so, very philosophically, I have settled the point that I like chickens, because we are all fond of young things, and we love to watch them, being hopeful of their future. To come now to lower things, and to adopt most properly a lower tone. I like to have each year at least one brood of a variety of fowls which I have not had before as chickens, or have not kept for a good many years. I look at them with the eye of a naturalist as well as of a poultry-lover. I love to watch habits and mark differences of character in different varieties—*e. g.*, how different is the Game chicken from the Cochin.

This spring I am watching, thanks to Miss Emily Beldon's kindness, a brood of Silver-spangled Hamburgs. By-the-way, let me observe that the sitting of eggs, thirteen in number, came rattling by rail all the way from Yorkshire to Wilts, a distance by said rail of at least two hundred miles. When I unpacked them and put them under one of my kind, tame, Cochin hens, my man remarked—"Well! purty lucky you'll be if you get half on 'em to hatch!" "What!" said I, "do you mean six chickens and a half?" "I mean six," said he stolidly, not hurt the least by my quizzing his mistake in calculation. Well, I had eleven hatched, and all doing well—one of the largest broods I was ever master of. So, my friends, never fear having eggs from a distance. At first my Hamburg chickens were little balls of fluffy, smudgy white, pately and indistinct in colour; but now, at a month's end, how the spangles are coming out! I admire the activity of the chickens, and the Hamburg symmetry is beginning to be seen—that neat active form and Partridge-like head. See them lying down in the sun by threes together, then on a sudden up go their heads, and up and away they go. I think the little pullets are handsomer than the cockerels. Query, Is it not so with Hamburgs through life? I like my brood hen to be happy, and I pity hens straining their necks through a wooden-barred coop while the chickens are sporting afar; in that case the poor hen is, by change of hours, either too hot or too cold, panting with open beak, or chilly in the shade, so I enclose a manure heap with wire-netting. There is a hedge all round which affords shade, and, therefore, all are happy, hen and ebicks, the mother not able by wandering to tire out the chickens, but able to be with them and scratch for and protect them. Then, being a Cochin, she does not fly over the low fence. Through or under the wire the chickens get into the garden, playing bo-peep under the rhubarb leaves, tearing at the weeds; and how they like the pull at the grass! new-cut grass is not half so agreeable to them. They appear to be kindly enough, honest, respectable little birds, unless bits of meat are given them; then how they steal, how they pilfer, how they run and hide, and swallow gluttonously and half choke themselves! yet as all are guilty in turn none can upbraid another. To my own Cochins they are a capital contrast, being so active and full of life. The other day down had come a young rook from the rookery near, and squatting on his haunches he sat near the chickens. What a child of wickedness he looked, blinking in the sun—a sort of Nicholas the younger. I thought of Milton, who describes Satan on the wall of Paradise, and says of him, "He sat like a cormorant;" but like good Christians with easy consciences, my Hamburg chickens did not seem to fear him.—WILTSHIRE RECTOR.

BEVERLEY EXHIBITION OF POULTRY AND PIGEONS.

FOR very many years past the repute of the Beverley Show has been great among poultry amateurs, and it undoubtedly well deserves their good opinion. The members of the Committee are mostly men of great experience in all matters appertaining to poultry, and uniting in their efforts to fulfil to the very letter every duty connected with the management of a poultry show. The Show continues open only for a single day, the birds are well cared for, and all are returned with the most unvarying punctuality by the first train on the following morning. Again, the plate prizes are most unquestionably of the absolute value they are represented to be, and the cups of this year are of as beautiful design as we have seen for many years past. The Norfolk Rooms are all that could be wished for as regards the accommodation which they afford a poultry show; the pens are those of Turner, of Sheffield, and the exhibition of plants and flowers, held on the adjacent grounds of Charles Reynard, Esq., all aid in enlisting public favour. In this portion of the Show the bouquets of flowers were an object of general admiration.

This period of the year is not, as a rule, a favourable one for the exhibition of adult fowls; the breeding season being far advanced, the plumage begins to look somewhat shabby, and not a few of the best hens are just now wisely permitted by their owners to enjoy the rest consequent on incubation. There was, nevertheless, as little to complain of on this point as could be expected, for most of those fowls entered for competition, being the property of experienced exhibitors, were shown in good feather. The *Game* classes were especially praiseworthy; Mr. Boyes, of Beverley, winning the silver cup for the best pen of Game with a pair of extraordinarily well-conditioned Ducksings, pressed closely, however, by Mr. Mathew, of Stowmarket, Sir St. George Gore, and Mr. Fletcher, of Manchester. The silver cup for the best single Game cock fell to the lot of Mr. Brierley, of Middleton, but this prize was equally well contested with those in the former Game classes. In *Spanish* fowls the Exhibition at Beverley was numerous as to the entries, and the quality was far beyond what is generally to be met with. In fact, many of the highly commended birds were of great excellence. In this class, as also in the following one, *Grey Dorkings*, the remarkably excellent condition of Viscountess Holmesdale's pens decided the victory, and added still another couple of silver cups to former successes. It is but justice to Mr. Martin, who has the care of her ladyship's poultry, to add that we never saw any birds sent on displaying better management. The *Buff Cochins*, and the *Partridge-coloured* also, were of great merit, the competition, though large as to the number of entries, being excellent throughout. Mr. Jennison, of Belle Vue, Manchester, obtained the silver cup for the best pen of Cochins, and reference to the prize list will show that most of our noted breeders competed. The class for *Partridge-coloured Cochins* was good throughout. The *Lamburgh* classes were far better than we anticipated, as so late in the season tells, especially against those varieties. Messrs. Beldon and Wood were the principal prize-takers. It is rarely that so good a class of *Pobalds* is found at any show. The White-crested were the victors.

Some especially good *Sultans* were exhibited in the Variety class; they were the property of Mr. Zurhorst, of Donnybrook. Their long journey from Ireland seemed not to have affected them in the least. Sir St. George Gore seemed to monopolise all the principal *Game Bantam* prizes with light-feathered, really "gamy"-looking birds in all points. The show of *Sabright Bantams* was unusually good, and the *Ducks* and *Whites* were also excellent.

The *Blacks* were good, more especially the Variety class, in which many of the rarest and most beautiful plumaged birds were well shown. The *Pigeons* were so perfect that almost every pen obtained a place in the prize list.

The day was most favourable.

GAME (Black-breasted and other Red).—First, S. Mathew, Stowmarket. Second, J. Fletcher, Stoneclough, Manchester. Highly Commended, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Commended, F. Sales, Crowle.

GAME (Any other variety).—First and Silver Cup, W. Boyes, Beverley. Second, J. Fletcher. Commended, Sir St. G. Gore, Bart.

GAME COCK.—First, C. W. Brierley, Middleton, Manchester. Second, Sir St. G. Gore, Bart. Highly Commended, W. Boyes; J. Fletcher; S. Mathew; M. W. Stobart, Darlington; C. W. Brierley; H. M. Julian, Hull.

SPANISH.—First and Cup, The Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, H. Beldon, Goitstock, Bingley. Highly Commended, E. Jones, Clifton, Bristol; Mrs. A. M. Holmes, Hotham; C. T. Bishop, Birmingham; J. Marchant, Halifax; J. T. Bottom, Bradford; H. Beldon. Commended, The Viscountess Holmesdale.

DORKING.—Cup, First and Second, The Viscountess Holmesdale, Highly Commended, M. Hunter, Green Hamerton; Sir St. G. Gore, Bart.; T. Burgess; J. Rolandson, Hawkhead, Lancaster; F. Smith, Driffield. Commended, C. Pease, Darlington.

COCHINS (Cinnamon or Buff).—First and Cochia Cup, C. Jennison, Belle Vue, Manchester. Second, Capt. Heaton, Lower Broughton, Manchester. Highly Commended, Rev. T. H. Barker, Hovingham; C. W. Brierley, Middleton, Manchester; H. Tomlinson, Balsal Heath Road, Birmingham.

COCHINS (Any other variety).—First, Capt. Heaton. Second, J. Stephens, Walsall. Commended, J. E. Greenhaigh, Harwich; E. Tudman, Whitechurch.

HAMBURGH (Gold-spangled).—First and Cup, H. Beldon. Second, Sir St. G. Gore, Bart. Highly Commended, G. Sutton, York; A. K. Wood; J. Newton, Silsden, Leeds.

HAMBURGH (Silver-spangled).—First, A. K. Wood. Second, H. Beldon. Highly Commended, J. Fielding, Newchurch; Sir St. G. Gore, Bart.; A. K. Wood.

HAMBURGH (Gold-pencilled).—First, H. Beldon. Second, S. Smith, Northwam, Halifax. Commended, T. Wrigley, jun., Tonge, Middleton.

HAMBURGH (Silver-pencilled).—First, A. K. Wood. Second, H. Beldon. Commended, E. Yearclay, Wisewood, Sheffield.

POLISH.—First, H. Carter, Uperthorpe. Second, H. Beldon. Highly Commended, Mrs. Procter, Hull; H. Beldon.

ANY OTHER VARIETY.—First, F. W. Zurhorst, Donnybrook (Sultans). Second, Sir St. G. Gore, Bart. (Black Hamburg). Highly Commended, J. H. Pickles, Todmorden (Brahmas); Hy. Beldon (Black Hamburg).

BANTAMS (Game).—First, Sir St. G. Gore, Bart. Second, Messrs. R. & E. Toder, Little Carlton, Newark. Highly Commended, C. Ashworth, Halifax.

BANTAMS (Any other variety).—First, F. L. Roy, Kelso, N.E. (Silver-laced). Second, J. W. Morris, Rochdale. Highly Commended, T. C. Harrison, Hull (Silver-laced); Sir St. G. Gore, Bart. (White); Messrs. S. & R. Ashton, Mottram, Manchester (Silver-laced); F. L. Roy (Silver-laced). Commended, Sir St. G. Gore, Bart. (Blacks); G. Manning, Springfield, Essex (Gold-laced).

BANTAM COCK (Game).—First and Bantam Cup, Sir St. G. Gore, Bart. **DUCKS** (Aylesbury).—First, J. K. Fowler, Aylesbury. Second, J. Storey, Warton, York. Commended, M. Harrison, Warton.

DUCKS (Rouen).—First, J. K. Fowler. Second, S. Stott, Rochdale. **DUCKS** (Any other variety).—First, T. Harrison, Hull. Second, Sir St. G. Gore, Bart. Highly Commended, J. R. Jessop, Hull.

PIGEONS.

CARRIERS.—*Cock*: First, F. Elsc, Bayswater, London. Second, J. Firth, jun., Webster Hill, Dewsbury. Third, E. Horner, Harewood, Leeds. Fourth, J. Thackray, York. Very Highly Commended, F. C. Bradley, Hall Cross House, Doncaster; J. Firth, jun.; H. Yardley, Market Hall, Birmingham; C. Cowburn, Leeds; K. Fulton, Deptford. Commended, H. Simpson, Whitby. *Hen*: First, K. Fulton. Second, H. Simpson. Third, H. Yardley. Fourth, J. Thackray. Very Highly Commended, R. Bellamy, Leven; F. C. Bradley, Doncaster; H. Yardley; C. Cowburn; E. Yearclay, Sheffield; F. Elsc, Bayswater. Highly Commended, J. Firth, jun. Commended, J. Firth, jun.

Mr. Challoner, of Workop, and Mr. Hewitt, of Birmingham, were the Judges of poultry; and W. W. Boulton, Esq., of Beverley, officiated among the Pigeons.

A TALKING BLACKBIRD.

ALTHOUGH from early childhood a great admirer of living birds, and having kept nearly every variety of song birds, an incident has just come to my knowledge for which I was not by any means prepared. A tenant of mine, one of a number of cottagers in my neighbourhood, reared a Blackbird last season, and his wife has taught it to whistle throughout perfectly "Pop Goes the Weasel," "The Chimes," and it will also call distinctly their dog by its name "Viper," and repeat a few other short words. Starlings I have repeatedly myself taught to whistle tunes and speak short sentences distinctly, but Blackbirds I imagined incapable of such tuition as singing tunes and talking. This particular Blackbird whistles in a very distinct undertone similar to the piping Bullfinch or the sound of a flageolet, and I should be glad to know from any of your readers whether its performances are as really unique as I suppose them to be.—EDWARD HEWITT, *Sparkbrook, Birmingham.*

P.S.—On my return from Woodbridge, on looking over the *Birmingham Daily Gazette*, I found the circumstance detailed in the paragraph enclosed; and as this poor animal was so very generally known for many years back as the first-prize winner in every case in which he competed, its reproduction would, I think, be interesting to many of your readers—more especially as "King Dick" was the size of "Remainie," the bull-dog, mentioned in your Sheffield report as being suffocated during its transit to the Sheffield Show. The end of poor "King Dick" forcibly brings to mind an epitaph on a bull-dog I once read many years back in a friend's garden. "Here lies Inevitable, a noted bull-dog, but an uncompromising hero." "His heart was honest, though his face belied it."

"DEATH OF THE CHAMPION BULL DOG.—The well-known

champion bull-dog "King Dick" has paid the debt of nature under rather peculiar and interesting circumstances. On Easter Tuesday Mr. Lamplier, of Handsworth, the owner of the dog, died. After that event "Dick" exhibited the most profound grief for the loss of his master. He would not rest anywhere except on the chair upon which his master used to sit; and whenever he could get into the room in which he died he gave expression to his feelings in the most vehement howlings, broken by low growls and other vocal signs of sorrow. He refused his food, and on Sunday last he followed his much-loved master. In fact, the faithful animal may be said to have died of grief. A rarer instance of canine affection and fidelity has seldom if ever been recorded."

ARTIFICIAL SWARMS.

HAVING some bees, I wish to increase them. One hive I have had eight years; the other two years. Now, I have been very unfortunate in my bee management, or, rather say, mismanagement, not to have more than one addition in eight years. Sometimes I do catch a swarm, and lose it in the winter, but generally the swarms go off when they like, and I see them no more.

Late last season some one wrote of artificial swarms, and referred to a back Number. On turning to that Number I was not much enlightened, for it only stated that the mode of proceeding was fully described in some remote Number, and not having that Number by me, I did not obtain the information, so I lost my bees.

As swarming season is at hand, will you detail the process of getting the swarms from the old cottage hive, without risk of loss? The information may suit some one else, as well as—
JOHN EVERGREEN.

[Having two stocks you cannot do better than follow the instructions already given by Mr. Woodbury, the substance of which we now repeat for your information. "Selecting the forenoon of a fine day, the whole of the inhabitants of one hive should with their queen be driven into an empty skep. This exodus having been effected, the swarm is formed, and the bees in their new and unfurnished domicile should at once take the place of the old stock. The original hive should also at once take the place of the second stock, which must be removed to a little distance, not necessarily beyond the limits of the apiary, but so far as to prevent absentees from readily discovering it; and it is well at the same time to disguise its outward appearance as much as possible. In its new position the stock will remain apparently dormant for a few days, but in about a fortnight will probably so far recover itself as to admit of being again employed in a similar manner. The bees returning to the old spot and missing their queen, will at first be in some confusion, but will ultimately settle down to their task of forming royal cells to supply her place."]

HARDINESS OF LIGURIAN BEES.

I AM pleased to say that my twenty-six stocks of pure Ligurian bees here have all passed through the winter in the best of health. Some of them were swarms made late in the season, and had only artificial food in the hive to live upon. None of the stocks had an ounce of food given to them from September to March. I did not lose a single stock here or in either of my other apiaries, nor did I in the previous winter lose one stock out of twenty which I then had here; so I begin to think that the Ligurian bees can stand our changeable winters better than the common black bees. I had my first two swarms on May 23rd, which is very early with us, as I never had more than one swarm of black bees in May in this locality.

The very severe frost (8°) we had on the night of the 29th of April threw the bees backwards a fortnight, and on the nights of May 14th and 15th we had 5° of frost.—WM. CARR, near Manchester.

EARLY SWARMS—BLACK BEES VERSUS LIGURIANS.—In the kitchen garden of E. Boyd Rice, Esq., of Dane Court, in the parish of Tilmanstone, near Sandwich, Kent, there are three stocks of bees, one of which sent out a swarm on the 8th of last month, another on the 14th, and the third on or before the 19th. In my own, and the neighbouring parishes several

swarms issued on the 16th, 17th, 18th, and 19th, and again on the 23rd, but the weather during the whole month has been most unfavourable for swarming, a strong easterly wind prevailing, which occasionally reduces the thermometer to 32° at night.—SIBERT-ON-THE-WOLD.

A TREBLE SWARM OF BEES.

ON the 20th of May, three first swarms belonging to a cottager in this neighbourhood (Taunton), all came off, pitched together, and were all put into a large ordinary straw hive, with a hole in the top. Upon lifting the hive in the evening we found it more than full of bees, so that in placing it on the stand, many were compelled to crawl outside. The owner was much alarmed, and knew not what steps to take; but after a little persuasion, I induced him to dress another hive, remove the stopper from the other, and place the newly-dressed hive upon it. I visited them on the following day, and several times since, when I fully expected to have seen large numbers killed, instead of which I have not been able to discover one dead bee, but find them all working well together, and in a few weeks hope to remove the super well filled with new honey.—LUKE TILLEY.

TOMTITS EATERS OF BEES.

THE question as to whether the tomtit, *alias* the "Hampshire bee-eater," is an eater of bees or not, having been discussed for some weeks in your columns, I beg to submit to your notice my own experience. In the beginning of the present spring, or rather when the weather became hot enough for the working of the bees, a tomtit was constantly lurking about the bee-hives, and feeding upon those unfortunates which had become entangled in some old spider webs, or from some accident were lying on the ground. It is, therefore, my opinion that the tomtit is only an eater of bees while they are in a helpless state.—WILLIAM C. ANDERSON.

OUR LETTER BOX.

WINE FROM UNSHIPPED GRAPES (W.B.).—Bruise and press the Grapes. To every gallon of the grape juice add a gallon of pure water. Take the bruised grapes from the press and restore them to the mash-tub, and bruise thoroughly again; then add as much water as you got pure juice from it at the first pressing; let it stand for an hour or two and press again; then put the liquid into your cask with the first pressing and the water which you have added to it. To every gallon of this mixture add three pounds of the best white sugar; let this be dissolved in the water before you add it to the grape juice, and give it a thorough fermentation. Keep your cask full, if possible, and let the yeasty substance work over at the bung, for this is the best way to get rid of the excess of mucilage, taking care to fill up the cask frequently with the must saved for that purpose. If, however, you have not a sufficient quantity of must to fill your cask and supply the waste from the bung, the following method may be adopted:—Take strips of cotton cloth, half an inch wide and 12 or 15 inches long, wet them and dip them in flowers of sulphur, light them at one end and put them into the cask, one end being secured at the bung; when the cask is filled with the vapours of the sulphur, pour in the must until the cask is about one-third full; put in the bung and roll the cask until the vapour is thoroughly mixed with the wine; repeat the process until all the must is in the cask; this will throw down the mucilage and colouring matter in which is contained the offensive taste and odour; as soon as this takes place, which will be in two or three days, draw off the must carefully, clean out the cask, replace the wine, and proceed with the fermentation as above.

INFERTILE SPANISH EGGS (*A Downted Beginner*).—You are having neighbours' fare. We have twenty instances of the same failure, and cannot account for it. There is nothing wrong in the ages of your fowls. Spanish have done worse than any other fowls this year; but as one egg of your hens was good, others should have been the same. They may have been chilled. Your fowls which peck off each other's feathers are feverish. Give them lettuce leaves, and remove for a time the cock whose face is pecked. The size of the egg has nothing to do with the size of the chicken.

POULTRY MARKET.—JUNE 1.

We have lately had the worst trade on record; and although the supply is by no means large, prices are hardly maintained. Our young poultry is evidently all suffering from the cold easterly wind.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 72.2°; and its night temperature 48° 3'. The greatest heat was 90°, on the 12th and 13th, 1812; and the lowest cold 36°, on the 15th, 1851. The greatest fall of rain was 0.84 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

FLUED WALLS—PROTECTING FRUIT TREES.

O "Bon" (page 366), we are indebted for the section of a flued wall; but it would appear that the object of the builder was to so construct his wall that the trees trained

over it would be roasted in some parts and starved in others—at all events, the wall when heated would have the effect of subjecting the trees to extremes of heat and cold.

We may not unreasonably conclude that the effects of these extremes were disastrous; and "Bon" informs us that "the Peach wall, 290 feet long, which had, some years ago, been artificially heated at no little expense and trouble by keeping sixteen furnaces going, has been "left unheated for years," though he assigns no reason for the disuse of the means for heating.

I can confirm your correspondent's statement as to the use of fires for heating Peach walls having been discontinued in certain cases for years; and having seen the effects of walls artificially heated in the manner described by him, I am enabled to state that the results were far from gratifying. I have also seen hot walls on which Peaches, Nectarines, and Apricots were grown satisfactorily, and ripened from a fortnight to three weeks earlier than on an unheated wall. That a heated wall should, in the majority of instances, be so injurious to the Peach trees trained upon it as to completely spoil the trees in a very short time, and on the other hand be so conducive to certainty and earliness of crop, I hope to be able to show is not due so much to the greater pains taken by those who are successful, but mainly to the construction of the wall not being such as to insure great extremes of heat and cold being avoided, and the wall not being so heated by the flues that a gentle warmth may be afforded from the bottom to the top. In building such walls a total disregard of the principle that an equal distribution of the heat to every part should be as far as possible secured, has led to the conclusion that flued walls are practically more injurious than beneficial to the trees trained on them. This I readily admit is true of the majority of hot walls as constructed, and of which "Bon's" section affords an example; but I differ from those who, because they see one or many hot walls so constructed that the fires cannot be lighted without proving injurious to the trees, come to the conclusion that Peaches, Nectarines, and Apricots have not been and cannot be grown on hot walls with a certainty of a crop.

It was not till 1851 that I saw Apricots, Peaches, and Nectarines grown on a hot or flued wall good as respects both crop and quality, and from a fortnight to three weeks earlier than from unheated walls. At the time named I was serving at a place where the garden was bounded on

the north by a wall 150 yards long and 13 feet high; the garden was a parallelogram 150 yards long by 100 yards wide, enclosed by walls 10 feet high, divided in the centre into two parallelograms 75 yards one way and 100 yards the other by means of a cross wall from north to south. There were the usual slips outside the walls. Now the north wall was a hot or flued wall, and the furnaces were to the north of this wall; one half the length of the south wall, or 75 yards, being occupied by Peaches and Nectarines, and the other half by Apricot trees. This wall, as well as the others, was rebuilt in the years 1830 and 1831, and in order to have the best walls and fruit-tree borders the gardener visited, through the kindness and liberality of his employers, the most noted places in the kingdom, and he gleaned this very important fact—viz., "No hot wall that I saw at any of the places visited, having the fires lighted, had a tree upon it worth looking at, or fruit on it worth naming; but though I saw hot walls in most of the gardens visited, the majority of them were not heated, the trees being protected by netting, which was found sufficient." It had been decided to flue the whole of the walls to protect the blossom of the trees from spring frosts, but so convinced was the gardener of the practical inutility and injurious effects of a flued wall to the trees upon it, that all the walls were built solid, except the wall already alluded to, and of that one half was flued after the manner described at page 366, and the other half in the way which I shall shortly describe. The part of wall flued after the manner described at page 366 was devoted exclusively to Peaches and Nectarines, and the other to Apricots, except two trees, which were Peaches. They were the original trees that were upon the Apricot wall, and the whole extent of the wall was covered; but the trees on that part of the wall occupied by Peaches were not the original trees, but a second planting, nine years old, and covering the wall entirely.

At the time mentioned I had the care of these walls and gardens, under the gardener (who lived to serve the family of his employer fifty years), and it was a rule to heat one-half of the Apricot wall in order to obtain fruit earlier than on the unheated part, the fires being lighted on cold frosty nights after the white of the blossom was generally distinguishable, and fires were continued on cold nights and days until danger from frost was over. In 1851 the fires were first lighted on the 21st of February, the netting having been on a fortnight earlier. On the 1st of March the protective netting was put on the Peaches and Nectarines, and the blossoms were so far advanced that I considered it desirable to light the fires belonging to the half of the Peach wall in order to have Peaches, as I thought, earlier than on the unheated wall, and I therefore had four furnaces set to work; but not knowing whether I was doing right or wrong, having no orders on the matter, I took the opinion of the gardener, then ill, and his answer was "Not to heat the Peach wall under any circumstances," but to keep the netting on day and night until the flowers opened, and to keep it on during frosty days afterwards.

The fires were discontinued for the Apricots after the third week in May until the fruit began to swell for ripening,

when they were relighted and continued day and night until the fruit was ripe. The Apricots were fine, and came in a fortnight or three weeks earlier than those on the unheated wall. I was only sorry that I had not treated the Peaches in the same way, and had them a fortnight or three weeks earlier than they were likely to be ripe. In the following year, however, I was to be gratified, for on that part of the wall to be heated were the two Peach trees, and I was eager to try the effect of heat on them. It was a rule to heat one half of the Apricot wall one year, and the other half in the next, and this year it came to the turn of the wall having the two Peach trees to be heated. This was in 1852; the nets were put on the Apricots in that year on the 1st of March, and on the Peaches on the 19th of March, and the fires were lighted when the days and nights were cold. The crop was again good, the fruit ripe on the side next the wall equally with that next the sun, and much to my satisfaction, the two Peach trees bore a good crop and fully a fortnight earlier than on the unheated wall. One of these trees was a Royal George, and on it I first saw downy and smooth-skinned fruit—that is, Peaches and Nectarines on the same tree. Why not have heated the half of the Peach wall, and have had Peaches earlier and thus prolonged their season?

The garden changed managers, the new manager did heat the Peach wall. (The trees had been eleven years planted, and with the riders or standards covered the wall.) The result was a fair crop, and some days earlier than on the unheated wall, but the trees were smothered with aphids and eaten up by red spider, and there was no fruit in the following year. In that year the other half of the wall was heated, and fruit was ripened some days earlier, but they were few. The heating of the wall was persisted in, and though I did not see the death of the trees, I saw fresh trees had been planted in their place in 1856. The Apricots still covered the wall, and the south wall (not flued), was still occupied by the original Peach trees producing a heavy crop of fruit.

Since that time, as well as before it, I have examined many flued walls, but have not seen any of them in use; and though I have a heated wall at present, I have not the courage to have a fire put in the furnaces, for I have tried a fire on cold frosty nights, and the only benefit I could ever perceive was that the fruit set with greater certainty; but whatever good the heating might effect was more than counterbalanced by the plague of insects that followed, and so sucked out the juices of the young shoots that the fruit fell before stoning.

For Peaches I am certain that no flued wall is necessary to secure a crop on south aspects on this side of the border, for they produce good crops without flued walls if due care is taken to retard the blossom, and to protect it and the young fruit up to the third week in May from wet and cold, by a covering of canvas or fine meshed netting. Except in elevated and cold localities Peaches can be ripened in our climate without the aid of flued walls or glass coverings, and the former are prejudicial rather than conducive to certainty of crop and improved quality of fruit. The Peach, I am certain, does not require any artificial roasting and starving to induce it to set its fruit; but, on the contrary, extremes of heat and cold during the setting and swelling of the fruit are injurious.

The effects of a heated wall appear to be very different as regards the Apricot; and as the radiation of heat from the bricks prevents the deposition of moisture on the blossoms, I think a hot wall does materially aid in the preservation of the future crop, besides saving from frost the setting and swelling young fruit, more tender than that of the Peach tree. The Apricot suffers but little from frost so long as the blossoms remain dry, but a very few degrees of frost will bring down the fruit in a few days afterwards like a shower of hail. If there is a fruit tree that flued walls can in the least assist in producing a crop, I think it is the Apricot, for it is not injuriously affected by a dry atmosphere, nor by one warmer in some parts than others, only it must have air. In a close moist atmosphere it will not fruit, hence the failures with the Apricot under glass, but having grown it on heated walls satisfactorily I can speak favourably of them. I have attempted to cultivate Apricots under glass and failed. I have seen others try to do so and they have failed likewise, and yet

we have it for certain that Messrs. Rivers and Pearson always obtain good crops.*

The following section is that of a flued or hot wall, such as I have seen covered with Vines producing Grapes in September, good as to size, colour, and flavour; and trees bearing Peaches, Nectarines, and Apricots with certainty, and no injurious effects were perceptible on the trees.

Fig. 1 shows a flued or hot wall 13 feet in height above the ground line *a*, and 15 feet from the foundation. The wall is not built perpendicularly but slopes inwards equally on both sides, being 31½ inches wide at the base, or 27 inches at the ground level and 18 inches wide at the top. It is built with 1½ inch cavities extending from the top of the lowest flue to the coping of the wall; and these cavities, or narrow chambers, become heated by the upper part of the flues, and afford heat to the wall between the flues. They are shown at *b*. The wall is built so that every other course of bricks crosses these chambers in

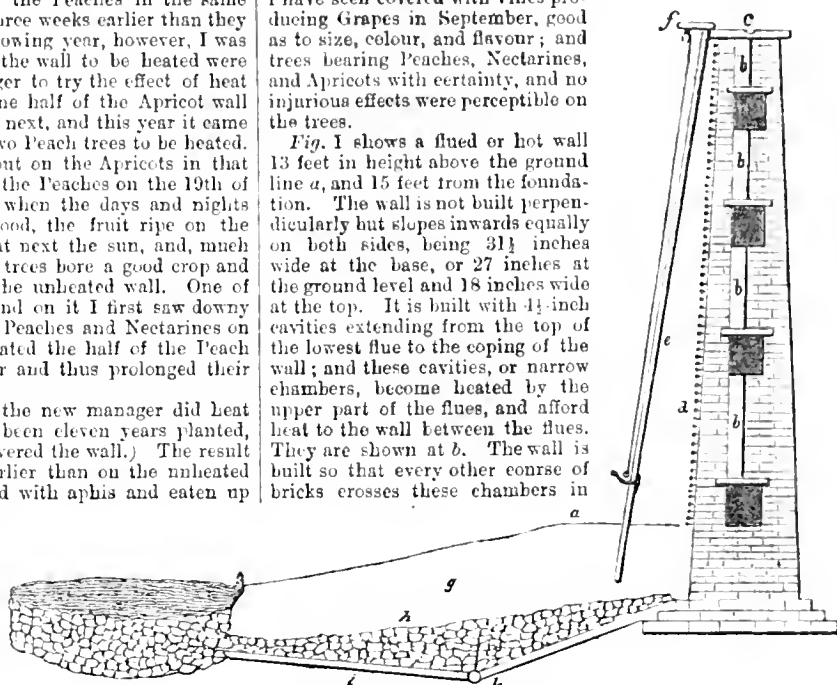

Fig. 1.

the manner of headers, every alternate brick being left out. The wall is equal to two bricks and a half thick. The chambers and flues render less bricks necessary. Its cost per superficial yard, including materials and labour, is 10s. Presuming that we had an acre to enclose in the form of a parallelogram, 272½ feet from east to west, and 160 feet from north to south, the cost of a flued wall of this kind for the northern boundary (there should be slips beyond the walls), will be £225. The coping projects over the wall 3 inches on each side, and there is no drip from it, as there is a groove in the centre of the coping at *c*. The joints are cemented, and there are gutters or grooves from the centre of the coping to the back (north side), at every 24 feet, the grooves in the coping being cut deeper at the "run off" to give the necessary fall. The wall is furnished with wires (one-eighth inch), 4¼ inches apart, as shown at *d*, the wires being passed through holes in holdfasts driven into the wall 2 inches, and projecting 1 inch. The wires when strained have a neat appearance; and the trees do equally well, if not better, trained in this way than when fastened close to the wall with shreds and nails, and the wall is no worse. Some walls that have been wired in this manner thirty-eight years have as good a face as when first erected, for the mortar has not been knocked and hammered out by the centinual driving in and drawing out of nails.

In front of the wall, *e* is intended to show a pole 2 inches square, placed 18 inches from the wall at bottom, and let into the ground, that part being charred and dipped in coal tar whilst hot. The upper end of the pole rests against the coping, and under an inch-deal board 11 inches wide, fixed to the coping by means of iron plates let into the coping and leaded in. This board, *f*, serves to exclude rain and to keep the canvas dry when rolled up, it being fixed to a roller, and drawn up or down by a cord and pulley. *g* is the border, *h* drainage, and *i* concrete; *k* is a drain. The netting used to protect the trees from frost is of wool, and has a quarter-of-an-inch mesh.

Fig. 2 is a similar wall, only part of the flues are pigeon-holed instead of chambered, which gives heat equally to the wall, and avoids excessive heat in some parts and coldness in others. The spaces, *a*, are flues, and the pigeon-holes are represented by the white spaces over them. This will be best

* In an orchard-house, of course unheated, we never failed to ripen Moorpark Apricots grown in pots.—Eus.

understood by *fig. 3*, which is an interior elevation of the wall, the shaded part being the flues and the black the brickwork. The white spaces show the openings left in the brickwork.

Fig. 2.

Fig. 3.

Fig. 4 is a section of a flued wall built solid, the flues being placed at different distances from the south side of the wall (on the right of the engraving).—greater at bottom, as there will be the most heat, and nearer at top, and correspondingly nearer between, as the heat will be less upwards.

Fig. 4.

Fig. 5.

These are the only descriptions of hot walls that I have seen used advantageously; and those I have worked built in accordance with "Bob's" section I have found more injurious than serviceable in any way. The cost of these walls is about equal, the latter, *fig. 4*, being the most expensive of the three. It is built plumb. The two first slope inwards; and in this I see an advantage, as the trees get many a refreshing shower, whilst those on a perpendicular wall get little rain, and are, besides, often surmounted by a coping projecting several inches, the utility of which I have striven to discern and have not been able.

Whilst writing about walls I will take the opportunity of saying, that of all the walls I have had to deal with none surpassed that shown in *fig. 5*, it being 12 feet above the ground level, and built pigeon-holed from top to bottom, which is a great saving of material; and an equally strong wall is secured as if built solid, and not so liable to give way as a narrower one, though taking the same quantity of bricks. Such a wall for the southern wall of a garden is desirable. It should be 18 inches thick and 14 feet 6 inches high, including foundation, and its cost about 4s. per superficial yard; so that a wall of this description 272½ feet long will cost £110.

Fig. 6 is a brick-and-a-half or 14-inch wall, 12 feet from the foundation and 10 feet from the ground level. On solid ground the foundation may be nearer the surface, and the wall have 12 feet of available surface for training trees; and its cost would be for a wall 160 feet long £50, at 4s. 9d. per superficial yard. Such a wall is suitable for the east and west sides. To enclose a garden, therefore, with walls is a very costly affair. Suppose the garden were two acres in extent, it would be best disposed of in the form of a parallelogram, having an equal area within as without the walls. To wall round a garden 272½ feet by 160, thus containing exactly an acre, and this is a nice proportion, giving a large extent of south wall, or walls running from east to west, consequently facing south, the cost would be as follows:—

Fig. 6.

Fig. 7.

North wall, flued as <i>fig. 1, 2, or 4</i>	£225
South wall, as <i>fig. 5</i>	110
West and east walls, as <i>fig. 6</i>	100
	£435

If the east and west walls were built the same as the south wall, then the cost would be £22 more, or £457; and if instead of a flued wall to the north, one the same as *fig. 5* were built and continued all round, the cost would be reduced to £342 for the enclosing of a garden containing an acre within the walls. This may seem a very large sum; but it is not so large by £95 as Mr. Thompson states in the "Gardener's Assistant" by the most expensive plan here given, nor so much by £210 according to the last (all built like *fig. 5*), plan. The prices are those of work done, but the price varies with the expense of materials, distance of cartage, and the rate of wages.

I have known instances of the east and west walls being flued, which to me seems a waste of material and labour, a thicker wall being necessary. With glass so cheap as it is, it really seems a waste of money to build walls, and especially flued walls, beyond those necessary for protection; and for this 14-inch walls and 12 feet high above the ground are as thick and as high as need be. More money has been often wasted on hot walls and thick walls than would have built a very nice range of forcing-houses; and fruit can be grown with much greater certainty in them than on walls however artificially heated. I am no advocate of flued walls, but I have seen finer and heavier crops of fruit—Peaches, Nectarines, and Apricots, on them than in all the unheated detached houses I have yet seen.

Another subject I should like to broach, and that is, the devoting of south walls exclusively to Peaches, Nectarines, and Apricots; or, where there is a large extent of wall, one or two Plums and Cherries may be planted, but this is the exception. It seems strange that the best aspect should be exclusively devoted to that which lasts in season but a short time, some having a notion that any aspect is good enough for Pears and Plums. I confess most Pears and Plums do fairly on west aspects; but I must say that the finer kinds, fine as they are on west aspects, are much finer when grown on a south aspect. If we are to derive any benefit from cheap glass, it must be in employing it for the growth of those fruits that are not unexceptional grown on walls; but though the fact is, that those fruits not bearing with certainty and to perfection on walls will do so if the wall be covered with glass, it really gives no one

credit to cover a wall because there are trees upon it, for it does not follow if the trees upon it do ill other kinds would be subject to like imperfections. I am mindful of what I have before written on this subject; and though I see nothing to retract, I certainly think that half of the Peaches, Nectarines, and Apricots at present grown on walls would be better grown under glass. They come in from a fortnight to three weeks sooner, and those on walls make a nice succession. If I see the necessity of occupying less wall with Peaches, I do not see the necessity of covering it with glass, but of erecting a large, wide, lofty span-roof house, and growing the fruit in it instead of on the wall, for I see Pears that are cracked, pitted, and spotted on west walls much larger, much finer, and far better coloured on south walls. The best Pears we have are grown on a south wall, though we have two west walls, one 12 feet and the other 20 feet high, not a foot of which is left bare, but is so thickly covered with foliage as to resemble an Ivy-covered wall, and yet though the fruit is large and fine, the best is from trees on the south wall, and the worst from espaliers and bushes, or pyramids. I only want more south or south-west wall for some Pears which do not arrive at that perfection on espaliers and west walls, that I think they would on south or south-west aspects. Aspect has a great effect on the size and colour of Pears, and exerts an influence on their ripening. A south aspect gives fruit ripening ten days sooner than a west aspect, and a fortnight or three weeks earlier than trees as bushes, pyramids, or on espaliers.

The cost of enclosing a garden with walls may seem heavy. Where high walls are out of the question on the score of expense, a wall or walls of less height and thickness may be advantageously employed as a protection to the garden from the north, which will give an available surface for the growth of Apricots, Peaches, and Nectarines. Fig. 7 is a section of a nine-inch wall 10 feet high from the foundation. A wall of this height and thickness will not stand unless supported by buttresses or piers of a thickness equal to that of the wall, and nearly twice that in length. They should be 9 inches one way and 14 inches the other, built up with and tied into the wall, and not more than 6 feet between. They, of course, must be to the north so that the plain surface may be southwards. Its cost is 3s. 9d. per superficial yard, or 12s. 6d. lineal. It is desirable to have wings at each end, so that the violence of the west wind and cold of the east may be broken and lessened. These may be 10 or 12 feet long, and the same height as the wall. The wall may be lower, but one 7 feet in height is quite low enough for Peaches and Nectarines, and I do not care about walls so low for Apricots and Plums.—G. ABBEY.

THOMSON'S STYPTIC.

This production of Mr. Thomson's will be found very useful for many purposes, besides preventing the bleeding of the Vine. One of such purposes is healing the wounds of succulent plants, and it will be found invaluable to the Pelargonium-grower. After a new variety has been purchased, most people are anxious to propagate it as rapidly as possible; hence it often happens, that many of the plants, as soon as their heads are taken off, dwindle away and die. This is almost sure to happen with the more delicate kinds, especially if they have been subjected to the high-pressure system of propagation, which is usually the case before they leave the nurseryman's hands. In many cases they are sent off direct from the propagating-house without being properly hardened off. The check they consequently receive during their journey very much injures them, and then, as soon as the purchaser gets hold of them he is very desirous of increasing their number as soon as possible. The work of decapitation is too quickly performed for the well-being of the plant, and it often happens that the plant and the cutting die in consequence. If proper care is taken in the management of the plant after it is received, if it has been packed several days, it should be gradually inured to the light. Great care should also be observed in watering it. Water should be used only in sufficient quantity over the foliage to prevent the plant from flagging; and as soon as the plant has commenced its root-action, water may be applied to its roots. These points having been carefully attended to, and a reasonable time allowed for the subject to recruit itself, it may have its head taken off, when Thomson's styptic steps in to its aid to prevent the wounded plant from taking injury, and the cutting from decaying.

As soon as the cutting is taken off, spread a thin coat of the

styptic over the wound; this will prevent any water penetrating by the wound, and allow the sap to perform its proper functions over the remaining portion of the plant. Water should, however, be withheld for two days; after that time the sap will have commenced circulating in its proper channels, and the general work of the plant will be commenced by its rapidly pushing out several young shoots below the cut. After the wounded plant has been properly cared for, the cutting may be operated on. Two or more of the leaves should be cut clean off close to the stem of the cutting, then spread a thin coat of the styptic over each of the wounds, and if a little of it is carefully spread over the centre of the base of the cutting, it will make all secure. Care must, however, be taken not to spread it beyond the ring of the woody part of the cutting, otherwise that part of it where the roots are emitted will be completely sealed up, as it is just between the bark and the wood where the cutting emits its roots. This will prevent the water from soaking into the cutting, and ensure its striking freely. It will also cause it to strike much more quickly, because the sap is prevented from escaping, and being sealed up, as it were, in the cutting, it commences circulating over the latter almost directly after it is put in, providing the cutting is not allowed to become exhausted by flagging. A great number of cuttings of the delicate kinds of Pelargoniums, such as Mrs. Pollock, are sure to be sacrificed in the early spring months; for, when the cuttings are taken off at that time, the plants do not possess sufficient vigour to heal their wounds quickly. The smallest amount of moisture that comes in contact with the wound will cause it to decay. I have often seen the shoots decay as much as 2 and 3 inches below the point where the cutting was taken off. Here, then, is a loss of from five to fifty per cent. of cuttings, according to the size of the plant. By a judicious use of Thomson's styptic this loss may be avoided, and the work of propagation may be carried on at an earlier period in the season. For young seedling plants it is very effective in preventing their decay after they have been beheaded. It will also prove a good substitute for grafting-wax, only in this case it will require two or three layers to be put one over the other as they become dry. Grafting will be much more easily done, and more effectually, with the styptic than it would be with wax. I mean, of course, for all kinds of small pot plants, such as Roses, Azaleas, Camellias, &c.

The styptic will also prove an excellent remedy for preventing the bleeding of all kinds of Ficus; in fact, it would be highly desirable to use it for covering the cuts whenever any are made on any kind of plant. Some of our great Geranium-growers would find it very advantageous if they used it for large specimen plants when they are cut down after their season of rest. By taking this extra trouble they would save the very topmost break, and very much improve the constitution of their plants.—J. WILLS.

MR. JOHN WATERER'S EXHIBITION OF AMERICAN PLANTS.

THE Exhibition of Rhododendrons and other American plants at the Royal Botanic Society's gardens, furnished by Mr. John Waterer, of Bagshot, is this year fully equal to what it usually is. Not only are the plants in profuse bloom, but they are massed in such a manner, and the ground is so well laid out for displaying the beauties of the various groups, that the effect of the whole is most excellent. The older varieties are here well represented by hundreds, we believe thousands, of plants; and of the newer kinds there is no lack. Some of these, however, at the date of our visit were not fully in bloom. Of those that were we remarked Alexander Adie, rosy scarlet; Raphael and Sir William Armstrong, crimson; Joseph Whitworth, lake, with dark spots; Mrs. Fitzgerald, rosy scarlet; and Duchess of Sutherland, white, bordered with lilac. Of varieties noticed as new last year, Earl of Shannon, Warrior, Sidney Herbert, and Lady Emily Peel again attracted attention.

TOBACCO-GROWING IN ENGLAND.

I HAVE not the Acts of Parliament at hand to which the communication of "X." (page 416), refers; but if the reference to the Acts by "W. C." as to the penalties be correct, I imagine that unless at least one rod or pole were planted no penalty could be enforced.

If the Act prohibits the growth of Tobacco, and then goes on to affix a penalty of £12 for every rod or pole of ground planted,

but says nothing about any less quantity, it is perfectly clear that no penalty could be enforced for planting a less quantity than a rod. The Act being a penal Act must be construed strictly. By "strictly," I mean strictly as against the makers, not the breakers, of the law.—P.

ROYAL HORTICULTURAL SOCIETY.

JUNE 5TH.

FLORAL COMMITTEE.—The great and leading interest of this meeting was occasioned by the circumstance of the Messrs. Veitch, of Chelsea, publicly receiving the challenge Orchid gold medal, value £20, offered and given by James Bateman, Esq. The Messrs. Veitch won this medal by obtaining the greatest number of certificates for Orchids exhibited at the Tuesday meetings during the years 1864 and 1865. Mr. Bateman remarked, when presenting the medal, that Messrs. Veitch had very far exceeded any other competitor in number of certificates. The splendid collections of Orchids which have been brought from the Royal Exotic Nursery on so many occasions for exhibition at the Tuesday meetings, have tended greatly to increase their interest; and every Fellow present on this day must have felt gratified at seeing the award so nobly contested for given to its worthy winners.

The Messrs. Veitch on this occasion sent twelve exquisite specimens of Orchids, which received a special certificate. First-class certificates were awarded to the following plants from the same firm:—*Nepenthes hybrida*; *Maranta tubispatha*, a very handsome spotted-foliaged plant; *Maranta roseo-picta*; *Kampernia Koscoena*; *Amaranthus* species, a very promising plant for budding-purposes, with long, narrow leaves, with golden and deep red variegation—it was supposed that it would prove a *Celosia*; *Arcaea Verschaffeltii*, a beautiful Palm; three distinct *Acers*, marked *b*, *c*, *d*, the last a very fine variety, with broad serrated foliage bordered by a delicate silver line; *Retinospora plumosa*; *Retinospora Veitchii*; *Retinospora* sp., with flat mossy-like branches; *Lycopodium* sp., an interesting plant in appearance resembling a small Conifer; *Gymnogramma Lanchama Thompsoni*, a crested variety. In addition to these were several interesting plants—those marked with an asterisk have received first-class certificates on other occasions:—A new *Coleus* (*Gibsonii*), which was requested to be sent again; *Panicum discolor*; *Acinetia* sp., a very beautiful Orchid, spikes of pale flesh flowers, with minute spots; **Acer polymorphum foliis dissectis roseo-marginatis*; **Darwinia fimbriata*; **Gynerium argenteum variegatum*; three seedling *Amaryllis*—*Bulle Blanchense*, Queen of the Netherlands, and *Belladonna*, pale-striped varieties; and **Retinospora obtusa aureo-variegata*.

Mr. Bull exhibited *Terminalia elegans*, three seedling *Nepthodians* from *N. multifidum*—mollis densum, confusus, and ramosissimum, and *Eranthemum argyronerum*, all of which were awarded first-class certificates. *Athyrium Filix-femina pulchrum* was awarded a second-class certificate; and from the same exhibitor came also *Lomaria falcata*; and *Cyrtanthus obliquus* (?)

Messrs. Osborn, Fulliam, exhibited cut specimens of *Prunus lasiantha* var. *azorica*, a very handsome hardy-flowering shrub, very superior to the common Portugal Laurel. A first-class certificate was awarded for it. From the same firm came also *Cotoneaster* sp. from Nepal, with pale red flowers, and a collection of cut hardy shrubs and plants. Mr. Munro, Lyme Regis, sent a fine truss of *Rhododendron Falconeri*, one of the beautiful Sikkim varieties, a very delicate bell-shaped flower. Mr. Green, gardener to W. W. Saunders, Esq., brought a fine collection of *Arads* and a specimen *Saurumatum asperum*. A special certificate was awarded this curious collection of plants. From the Rev. G. Cheere, Papworth Hall, came seedling *Pelargonium Huntsman*, foliage broadly zoned; the flowers had suffered from the journey, but it appeared a promising variety; also four fine plants of the large-flowering *Mignonette*, specimens of which have been so often exhibited and admired this spring. Mr. Turner, West Derby, sent cut specimens of four seedling *Pelargoniums* of the Dr. Andre section, with crimped edges to the petals; and the Rev. T. Medland, the Rectory, Steyning, sent a large box of cut spikes of flowers of *Panlowmia imperialis*, which were awarded a special certificate. James Bateman, Esq., exhibited a cut specimen of the saporb *Dendrobium Wardianum*, the most beautiful of the family; a first-class certificate was awarded it. Mr. Bateman likewise sent several other beautiful cut specimens of Orchids; Mr. Butley, a seedling *Gymnogramma chrysophylla*; Mr. Taplin, the Gardens, Chatsworth, cut specimens of *Jonesia asoca*, a curious Leguminous plant, which has rarely been seen in flower in this country. From the Society's gardens came several pots of an old and pretty favorite annual, *Oxalis rosea*; also a plant of one of Mr. Weir's *Dieffenbachias* with mottled foliage.

FRUIT COMMITTEE.—Mr. Bradley, gardener to Mrs. F. Norton, Elton Manor, Notts, exhibited some remarkably fine fruit of Sir Joseph Paxton Strawberry, each berry weighing at least an ounce, finely coloured, and excellent in flavour. These were intended to show how well the variety is adapted for moderate forcing. A dozen pots of Sir Charles Napier, the plants bearing freely, were also sent from the Society's garden at Chiswick. Two Queen Pinea, exhibited by Mr. Miller, gardener to Lord Craven, Combe Abbey, Coventry, weighing almost 5 lbs., and the produce of plants nineteen months old, excited

much admiration; but fine as this exhibition of Mr. Miller's was, it was surpassed by that which he produced at the Regent's Park on the following day. The only other fruit exhibited were well-coloured Kirge Nectarines, shown by Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, but which were not brought before the Committee.

FORNIGHTLY MEETING.—The Bishop of Winchester in the chair. After the election of sixteen new Fellows, the awards of the Floral Committee were announced by the Rev. Joshua Dix, and Dr. Vogg offered some remarks on the subjects brought before the Fruit Committee. Mr. Andrew Murray then brought under the notice of the meeting part of a branch of the common Laurel sent by Mr. Pearson, gardener to W. Child, Esq., Kinet, near Bewdley, from which the bark had been peeled four years ago for a distance of upwards of 2 feet in length. Contrary to the opinion of Thomas Andrew Knight, Esq., and other vegetable physiologists, who consider that the bark when once wholly destroyed cannot be reproduced, new bark was formed. This result was attributed to the fact that the Laurel was in a thicket, and, therefore, not fully exposed to the drying influence of the air; had it been so, and had the season been dry instead of wet, no new bark would, probably, have been formed.

Mr. Bateman then presented his challenge medal to Mr. Veitch, as being the exhibitor who had in two consecutive years gained the greatest number of marks for Orchids at the fortnightly meetings. Each year, Mr. Bateman remarked, Mr. Veitch had gained an overwhelming majority of marks; but one of the conditions on which the medal was offered having been that the same person would not be allowed to compete till some else had won a medal, Mr. Veitch would, for a time at least, be prevented from entering the field, and then, Mr. Bateman remarked, it might, probably, be necessary to make him carry weight. Mr. Veitch in returning thanks alluded to the good which had been done by the Regent Street meetings in days gone by, and expressed his gratification at their revival in the present fortnightly meetings. The establishment of these had been of the greatest benefit to the Society—had done more to benefit it than, perhaps, any other act of the Council, and though debarred from competing for Mr. Bateman's challenge medal for at least two years, he would always have the greatest pleasure in giving these meetings his hearty support by sending to them his plants, and when again eligible he would be the first to contest it.

The Rev. M. J. Berkeley remarked, in allusion to the case of the peeled Laurel reproducing bark, that a similar instance had occurred in his own neighbourhood in the case of an Oak tree, which had been deprived of its bark for a distance of 3 feet, but had formed fresh bark and new wood from the ends of the medullary rays. A Sikkim *Rhododendron* sent to the last meeting to be named, was then stated to be *R. Blandfordianum*, of Hooker, a species of which the seedlings are extremely variable in their flowers, and it was further remarked that it, as well as *R. cinnabarinum*, is poisonous to animals, and that the smoke from the wood when burning causes inflammation of the eyes. *Marantas* were next alluded to, particularly *M. roseo-picta* and *M. tubispatha*, which was stated to be the *Calathea tubispatha* of the "Botanical Magazine." The *Cyrtanthus* shown by Mr. Bull was also said to be a variety of *C. obliquus*, which was figured many years ago in the same publication. Attention was also directed to *Arcaea Verschaffeltii*, a dwarf hybrid *Nepenthes*, and an orange and red-leaved plant belonging to the natural order *Amaranthaceae*, raised from seed sent home from the New Hebrides by Mr. J. G. Veitch, all of which were exhibited by Messrs. Veitch. The last, it was remarked, was probably a *Celosia*. The next subject which occupied attention was a handsome Laurel, exhibited by Messrs. Osborn under the name of *Prunus lasiantha* var. *azorica*, and which, combined with great hardiness, has the merit of producing larger and finer flowers than the Portugal Laurel, and that when the bushes are but small. A small *Cotoneaster*, and the beautiful Japanese Maple exhibited by Messrs. Veitch, were then noticed; and in connection with Maples it was observed that they were not so much cultivated as they should be, and that many fine species exist in the garden at Chiswick. These it had been determined to propagate for distribution, as they would certainly not be less prized by the Fellows of the Society than tender plants, which comparatively few could grow. A branch of Silver Fir, from Major Pench, of Bristol, next came under notice. In this the foliage had assumed an entirely different character from that which it usually presents, and had, moreover, become deciduous. This result was ascribed to a minute parasitic fungus on the under side of the leaves, which had only once before been observed in England, but is common in the Black Forest. A curious monstrosity in a Cabbage leaf was then referred to. In this instance, from the upper side of the midrib several distinct pairs of small blades had been produced, as if several leaves had become confluent; but on examination it was found that there was no fusion of vascular bundles, the number of these being the same as in normal leaves, and it was further found that every rib was inclined to become profliferous. This monstrosity Mr. Berkeley considered likely to throw light on the production of double flowers. A somewhat analogous case was recorded by M. De Candolle in the fifth volume of the Old Series of the Society's "Transactions."

Mr. Bateman then drew attention to several photographs of *Wellingtonia gigantea*, as seen in its native valleys in California, and to a section of the bark upwards of a foot in thickness, brought to the

meeting by Mr. Veitch. The appearance of this was not inaptly compared to that of a large cake of ringerbread. *Jonesia asoca*, of which flowering shoots were exhibited by Mr. Tuplin, gardener to the Duke of Devonshire at Chatsworth, and who, it will be remembered, also exhibited *Amherstia nobilis* in flower, was the next subject brought under notice. The *Jonesia*, Mr. Bateman remarked, was named after Sir William Jones, the celebrated oriental scholar and linguist, and belonged to the great family of Leguminosae, like the *Amherstia*, in company with which it was found by Dr. Wallich, who considered it almost equal in beauty to that tree. The *Jonesia* was figured in the "Botanical Magazine," t. 3018, and described as having large, glossy, pinnated leaves, with from three to five pairs of leaflets. The flowers, which are in terminal clusters, are not unlike those of an *Ixora*, and according to their age are pale yellow, bright orange, or orange scarlet, growing deeper in colour every day. They are fragrant just after sunset and before sunrise. The plant was also described by Dr. Roxburgh, and is figured in Bredde's "Hortus Malabaricus," and "Paxton's Flower Garden;" the plate in the latter work having been taken from specimens flowered at Chatsworth. Seeds of it were first sent to the Liverpool Botanic Garden by Dr. Carey. As the *Jonesia* and *Amherstia* were two of the most magnificent of Asiatic flowers, Mr. Bateman said that he would next allude to one found by Dr. Welwitsch in Africa, and which was reported to transcend all other African flowers. It was a species of *Camoesia*, and was figured in the "Transactions" of the Linnean Society, where the flowers are described as being nearly a foot long, and in colour milk white, edged with gold. The plant producing them was stated to be a climber of most vigorous growth, and therefore no difficulty need be apprehended in its cultivation if it be but once introduced into this country, and Mr. Bateman expressed a hope that some enterprising nurseryman would take steps to import it. Passing on to the Orchids, Mr. Bateman said that his remarks on these must be brief; he would, however, draw attention to *Anguloa Clowii* with two flowers on the same spike, exhibited by Mr. Anderson, of Meadow Bank, near Glasgow, who, it was stated, considers that all that is necessary to increase the numbers of flowers on the spikes of Orchids is cultivation. Among other Orchids noticed were the charming *Dendrobium infundibulum* with paper white flowers, stained in the throat with Roman red; *D. Wardianum*, which had been erroneously supposed to be the same as *D. Falconeri*; and *Odontoglossum Reichenheimii*. Though Orchids had done so much to please the eye, remarked Mr. Bateman, they had as yet done little for the palate, but on this occasion the Fellows and their friends would have an opportunity of tasting Orchid tea, and this he assured them from personal experience they might do with perfect safety. It was made from the leaves of *Angreum fragrans* imported by Bousquin, of Paris, from Réunion, where it goes by the name of Faham. It is described by its importer as being much esteemed in that island and in Mauritius as a beverage, and, as such, to have some advantages over tea, an opinion, however, in which those who tasted it did not appear to coincide. Cigars made of Orchid leaves, cases in Tobacco leaves, also came from the Museum at Kew.

Five Societies were on this occasion admitted into nniou.

MESSRS. WATERER AND GODFREY'S RHODODENDRON SHOW.

ATTENTION was directed last week to the fine display made by the Knap Hill plants at South Kensington, and some further remarks promised. Though there are several seedlings in or coming into bloom, these for the most part are as yet unnamed; mention of them must therefore be deferred till another occasion. Among the newer named kinds we remarked H. H. Hunnewell, Charles Dickens, Stella, Mrs. W. Bovill, Lady Clermont, Alexander Dancer, and Mrs. John Clutton, all of which were noticed last year as striking varieties. In addition to these, H. W. Sargent, Francis Dickson, and Lady Armstrong, are brilliant varieties, the latter with very large trusses. *Carcetaeus*, Charles Bagley, Mrs. R. S. Holford, a salmon rose, and Mrs. Milner, are also especially noteworthy.

ROYAL BOTANIC SOCIETY'S SHOW.

JUNE 6TH.

Nor a few predicted that this would be merely a repetition of the International Horticultural Exhibition on a limited scale, that the interest would be gone and the flowers faded; but it was not so, for in most cases the plants were not the same, and the flowers were not faded, but exhibiting a freshness and brightness only surpassed in May. Moreover, that the interest was not gone, the numerous attendance of visitors, the length of time that they lingered before favourite objects, and the consequent difficulty which there was at all times during the afternoon in approaching the plants, constituted, we think, a sufficient proof.

STOVE AND GREENHOUSE PLANTS.—The collections of these were numerous and in excellent condition, both as regards health and bloom.

From Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, came a fine collection of ten, including *Allamanda grandiflora* in remarkably fine bloom; a splendid specimen of *Pimela decussata*, densely covered with rosy blooms; *Polygala acuminata*, producing its purple flowers very freely; and *Acrophyllum venosum*, small but in great perfection. The white-flowered *Epacris pulchellum*, and *Chiozema Heuchmanni* and varium nanum were shown in excellent condition by Mr. J. Wheeler, gardener to J. Philpott, Esq., Stamford Hill; and in a beautiful collection from Mr. Rhodes a fine *Allamanda grandiflora*, producing numbers of its large clear yellow flowers, was very effective. This plant, we believe, was raised from Mr. Peed's, and though not equalling it in the number of flowers, was a handsome vigorous specimen. From the same exhibitor there were also large admirably bloomed plants of *Adeuandra fragrans*, *Erica Cavendishii*, *Erica Kingscottiana*, one of the tricolor race, the deep crimson *Phanocoma prolifera*, *Genethyllis Hookeri*, and the finest *Dracophyllum gracile* in the Show. Messrs. Lee sent, among others, fine specimens of *Pimela Hendersoni*, *Adeuandra fragrans*, *Ixora coccinea*, and *Acrophyllum venosum* with large spikes of bloom. *Rhynchospermum jasminoides*, trained in a free, easy style, and in fine bloom, was shown by Mr. Donald, gardener to J. G. Barclay, Esq., Leyton; and very good specimens of the same plant came from Mr. Kemp, Mr. Williams, Mr. Kalle, Mrs. Glendinning and Sons, and others. Mr. Donald and Mr. Williams also exhibited *Clerodendron Thomsoni*, bearing a profusion of its beautiful scarlet and white blossoms; and its variety *Balfourii*, with larger flowers, and which will probably prove more effective as an exhibition plant, came from Mr. Parker, of Tooting.

In other collections besides the plants above named we noticed *Boronia tetrandra*, *Tetratheca verticillata*, covered with its pendulous purplish-violet flowers, the lilac *Tetratheca ericaefolia*, *Combretum purpureum*, *Coleonema rubra*, the brilliant scarlet *Erica westphalingia*, *Medimilla magnifica*, *Stephanotis floribunda*, *Allamanda cathartica*, *Statice Holfordi* and *profusa*, *Eriostemon*, *Hoya bella*, which, however beautiful, is not very effective as an exhibition plant, owing to the drooping character of its blooms; *Aotus gracillima*, with long terminal spikes of yellow and brownish crimson flowers, *Aphelxus*, *Vincas*, *Azaleas*, and various *Heaths*.

Awards—For ten: first, Mr. Peed; second, Mr. J. Wheeler, gardener to J. Philpott, Esq.; third, Mr. Kemp, gardener to Earl Percy, Albany Park; fourth, Mr. G. Wheeler, gardener to Sir F. Goldsmid, Bart. For eight (Nurserymen): first, Mr. Rhodes; second, Messrs. J. & C. Lee; third, Mrs. Glendinning & Sons; fourth, Mr. Williams. For eight (Amateurs): first, Mr. Donald; second, Mr. Carson, gardener to W. R. G. Farmer, Esq., Cheam; third, Mr. Kalle, gardener to Earl Lovelace, East Horsley Tower, Ripley; fourth, Mr. Colea, gardener to R. H. Page, Esq., Beckenham. For six: first, Mr. C. Smith, gardener to A. Anderson, Esq., Norwood; second, Mr. Wilkie; third, Mr. A. Ingram, gardener to J. J. Blandy, Esq.; fourth, Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton.

FINE-FOLIAGED PLANTS AND FERNS.—Excellent collections of these were shown by Messrs. Williams, Barnard, Young, of Leigh Park, Taylor, and Young, of Highgate. Among the fine-foliaged plants from Mr. Williams were *Alcaesia Lowii*, with its conspicuously veined deep green leaves more than 1½ foot long, and about a foot wide; one of the finest specimens of *A. metallica* ever exhibited, and measuring about 3 feet across; Variegated Aloe-leaved *Yucca*; noble specimens of *Latania borbonica*, *Chamaerops humilis*, *Cycas circinalis*, and *Zamia pungens*; *Dion edule*, with fronds 5 feet long; *Dracaena lineata*, *Cyathia dealbata*, and the variegated New Zealand Flax, which, being distinctly striped with yellow, proves very effective. Other collections included *Eucephalartos latifrons*, *Rhopala*, one or two remarkably fine *Theophrastus*, *Phlomidrom pertusum*; *Pandanus reflexus*, elegantissimus, and javanicus variegatus; Variegated *Crotons*, *Maranta zebra*, *Aralia reticulata*, with prettily veined leaves; *Beaucarnea glauca elegans*, and *Billbergia zonata vittata*, with pale green leaves transversely barred with white. Among exotic Ferns were fine specimens of *Cibotium Schiedei* and princeps; *Gleichenia senivestita* and *spelnaca*; *Dicksonia antartica* and *squarrosa*; *Cyathia medullaris*, *Pteris argyrea*, Bird's-nest Fern, *Adiantum trapeziforme*, and *Woodwardia radicans*. In hardy Ferns, Messrs. Williams, as usual, took the lead in the class for twelve, besides contributing a numerous collection comprising many remarkable forms.

Awards—For ten fine-foliaged plants: first, Mr. Williams; second, Mr. Young, gardener to W. H. Stone, Esq., M.P., Leigh Park, Havant; third, Mr. Young, gardener to R. Barclay, Esq., Highgate. For six: first, Mr. Williams; second, Mr. Taylor, gardener to J. Yates, Esq., Highgate; third, Mr. Donald, gardener to J. G. Barclay, Esq. For twelve Exotic Ferns (Amateurs): first, Mr. Barnard, gardener to J. Taylor, Esq., Stoke Newington; equal second, Mr. Young, Havant, and Mr. Taylor; third, Mr. Young, gardener to R. Barclay, Esq. For twelve (Nurserymen): first, Mr. Williams. For twelve hardy Ferns: first, Messrs. Ivory; second, Mr. Kemp.

ORCHIDS, instead of being placed as heretofore on a turf bank in the large tent, were ranged in the narrow extension where the cut flowers and fruit are shown. In a collection of ten from Mr. Penny, gardener to H. H. Gibbs, Esq., Rogent's Park, there were *Odontoglossum citrosium* and *navium*, the latter with seven spikes; the beautiful *Phalaenopsis Luddemanniana* with nine blooms; a fine *Cattleya Mossie*, *Cyripedium levigatum*, and *Dendrobium Parishii*. From Mr. Wilson, gardener to W. Marshall, Esq., Enfield, came the

plant which excited the most interest among the Orchids—namely, a new *Oncidium* from the Organ Mountains, and named by M. Reichenbach O. Marshallianum. The flower measured quite $1\frac{1}{2}$ inch in diameter, and had a clear yellow lip and brown petals and sepals. From the large size of the flowers and their distinct colours it will, doubtless, prove an acquisition, especially as it may be expected to flower more freely in course of time. In the same collection were *Cypripedium candidum* with six finely-coloured blooms, having the tail-like appendages 2 feet or more in length, and *Tropidium Lindenii* with three blooms. In other collections we noticed good examples of *Cattleya Acklandiae*, C. Mossie, *Lucilia purpurata*, *Dendrobium formosum giganteum*, *Acridies*, *Succolabium praeorsum* and *corvifolium*, *Anguloa Clowessii* with four blooms, *Vanda navis* and *insignis*, *Oncidium sessile*, crispum, a very long spike of *leucochilum*, and *sphecatum* in fine bloom, *Phajus Wallichii* flowering profusely, *Odontoglossum citrosum* and *Pescatorei*, *Cypripedium barbatum*, *Hookeri*, *Veitchii*, and *venustum*, and *Oreelis foliosa*.

Awards—For ten: first, Mr. Penny; second, Mr. Wilson; third, Mr. Bullen, gardener to A. Turner, Esq., Leicester; fourth, Mr. Robson, gardener to G. Cooper, Esq., Old Kent Road; fifth, Mr. Page, gardener to W. Leaf, Esq., Streatham. For six: first, Mr. Williams; second, Messrs. Lee; third, Messrs. Jackson & Sons; equal fourth, Mr. Parker, and Mr. Bull. For eight: first, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; second, Mr. Young, gardener to W. H. Stone, Esq.; third, Mr. Peed; fourth, Mr. Wilcock, gardener to Dr. Pattison, St. John's Wood.

AZALEAS.—Large specimens were past their best, but some of less size than at the earlier Shows were exhibited in excellent condition by Mrs. Glendinning & Sons and Mr. Carson.

Awards—For six (Amateurs): first, Mr. Carson; second, Mr. G. Wheeler. For six (Nurserymen): first, Mrs. Glendinning & Sons; second, Messrs. Lee; third, Mr. Rhodes; fourth, Messrs. Cutbush & Son.

HEATHS.—Of these there were several excellent collections, consisting of the same kinds as noticed in previous reports.

Awards—For nine: first, Mr. Rhodes; second, Messrs. Jackson. For eight: first, Mr. Peed; second, Mr. J. Wheeler; third, Mr. G. Wheeler; fourth, Mr. Kemp. For six: first, Mr. Ward; second, Mr. A. Ingram; third, Mr. Young, Havant; fourth, Messrs. F. & A. Smith.

ROSES.—Nice groups of pot plants were furnished by Messrs. Francis, of Hertford, and Messrs. Paul & Son, who were first and second in the Nurserymen's class, and by Mr. Terry, who received a first prize in the Amateurs' class. Of cut blooms there were beautiful examples of *Marchal Niel* from Messrs. Paul & Son and Mr. Mitchell, of the Pittdown Nurseries, those from the former being especially fine. *Alba rosea*, *Gloire de Dijon*, *Louise de Savoie*, and *Scouteur Vaise* in Messrs. Paul's boxes, and *Joséphine Maitou*, *Madame Fillion*, *Centifolia rosea*, and *Marguerite Dombain* in Mr. Mitchell's, were conspicuous for their beauty. From J. Hollingworth, Esq., Maidstone, came excellent blooms grown out of doors.

Awards—For twenty-five (Nurserymen): first, Messrs. Paul & Son; second, Mr. Mitchell. For twenty-five (Amateurs): first, J. Hollingworth, Esq. For twenty-four: first, Mr. Mitchell; second, Messrs. Paul & Son; third, Mr. Turner.

PELARGONIUMS constituted one of the best features of the Show, and rarely have the show varieties been seen in greater perfection. Such plants as those exhibited by Mr. Bailey, gardener to T. T. Drake, Esq., Shardeloes, measuring from 4 to 5 feet across, and withal in profuse bloom, were surprising even to those who had seen his fine exhibitions of former years, and equally so were Mr. Turner's plants, and some of Mr. Fraser's. In the Amateurs' class Mr. Bailey, who, it is scarcely necessary to remark, was first, had very large and fine plants of *Flora*, *Lord Clyde*, and *Spotted Gem*, *Lady Cunningham*, *Ariel*, *Middle Patti*, *Nestor*, *Desdemona*, and *Golden Hue*. Mr. Nye, gardener to E. B. Foster, Esq., who was second, had excellent plants of *Desdemona*, *Sir Colin Campbell*, and *Spotted Gem*, also *Lord Clyde*, *Guribaldi*, and *Rose Celestial*. In the Nurserymen's class Mr. Turner was first with splendid plants of *Confagrato*, *Lord Clyde*, *Desdemona*, *Fair Rosamond*, *Fairest of the Fair*, *Beneon*, *Pericles*, *Viola*, and *Middle Patti*; and Mr. Fraser second with, amongst others, remarkably fine examples of *Rose Celestial*, *Lord Clyde*, and *Sausparril*. Of fancy varieties Mr. Bailey, Mr. Turner and Mr. Donald exhibited very good specimens, consisting of *Crystal Beauty*, *Marionette*, *Lady Craven*, *Lucy*, *Delicatum*, *Edith*, *Roi des Fantaisies*, *Udine*, *Miss-in-ber-Teens*, *Arabella Goddard*, &c.

Awards—For nine (Amateurs): first, Mr. Bailey; second, Mr. Nye; third, Mr. Ward; fourth, Mr. Wiggins. For nine (Nurserymen): first, Mr. Turner; second, Mr. Fraser. For six fancy (Amateurs): first, Mr. Bailey; second, Mr. Donald; third, Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hanstead. For six (Nurserymen): first, Mr. Turner; second, Mr. Fraser.

NEW PLANTS, &c.—Large collections of new plants were exhibited by Messrs. Veitch and Mr. Bull, but nearly all have been noticed in our Floral Committee and other reports. From Mr. Parker, Tooting, came a *Silver Fern*, *Nothochlæna cretacea*, and *Polypodium menyanthum* with large, bold fronds; and from Messrs. Ivery several new varieties of hardy Ferns, to which allusion has already been made. Messrs. Jackman contributed *Clematis Alexandra*, *Velutina purpurea*, very deep violet purple, and *Magnifica*, longitudinally banded with red. Of Beaton's *Pelargoniums* Mr. William Paul exhibited a fine

collection, in which were several *Nosegays*; and St. George, Sir Joseph Paxton, and *Crimson Queen* received first-class certificates; and a like award was made to Mr. Watson, St. Albans, for *Excelsior*, a salmon-scarlet *Nosegay*. Mr. Turner, Slough, also received certificates for *Fancy Sylvia*, a pretty light variety; *Tormentor*; *Favourite*, with a dark top edged with crimson and a white throat; *Lord Lyon*, dark top, white throat, and lower petals rose, flushed with violet; *Rustic*, and *Nosegay Duchess of Sutherland*. *Negress*, *Milton*, and *Union* from Mr. Nye, also received first-class certificates; and a similar distinction was conferred on *Gloire de Nancy* from Messrs. E. G. Henderson and Co., a double scarlet, as well as on *Lady Callam*, a charming tricolor-leaved variety. By the same firm and Messrs. Carter & Co., excellent groups of similar kinds were also shown. *Petunia Illuminator*, a showy variety in the way of Mrs. Ferguson, was exhibited by Mr. G. Clarke, Brixton Hill.

MISCELLANEOUS.—Among these subjects may be included *Pansies* from Messrs. Downie & Co.; Hooper, of Bath; Fraser, of Belmont, Edinburgh, and Kingston; and *Pinks* from the last named. Baskets of ornamental plants, came from Messrs. Cutbush, and *Camellia*-flowered *Balsams*, *Agaves*, and beautiful *Anæthochils*, from Mr. Williams. *Cytisus Labarum* *Alkekengi*, with long racemes of yellow flowers, and blooms of *Panlowia imperialis* were shown by Messrs. Paul and Son; and a fine basketful of the same by Mr. Masters, gardener to the Earl of Macclesfield, Sherborne Castle, Oxfordshire. Several pots of the pretty hybrid *Aubrietia Campbellii*, the variegated *Crested Dog's-tail Grass*, which has before been noticed as extremely ornamental, *Blandfordia nobilis grandiflora* with showy orange blossoms, *Variegated Maize*, and a numerous and very fine collection of variegated and coloured-leaved herbaceous plants, were exhibited by Messrs. E. G. Henderson. *Variegated Munze* and *Ornithogalum thyrsoides album*, in addition to the variegated *Pelargoniums* already noticed, came from Messrs. Carter & Co.; and well-grown *Fuchsias* were shown by Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, and Mr. Cannell, Woolwich.

FRUIT.

The show of fruit was good without being extensive, with the exception of Grapes, which were numerously exhibited and in great perfection.

PISEA.—The only Providence shown was one of $7\frac{1}{2}$ lbs. from Mr. Westland, gardener to Lord Belper, Kingston Hall, to which a first prize was awarded. To make up for this deficiency Queens were well represented, and of a weight but rarely seen of late years. Mr. Miller, gardener to Lord Craven, Combe Abbey, was first with a handsome fruit of $5\frac{1}{2}$ lbs.; and he also exhibited, not for competition, half a dozen weighing 4 lbs., 4 lbs. 7 ozs., 4 lbs. 10 ozs., 5 lbs., 5 lbs. 3 ozs., and $5\frac{1}{2}$ lbs., thus showing that he was able not merely to produce one fruit of extraordinary weight, but many equally good. No better proof of good cultivation than this could have been afforded. Mr. Barnes, Bicton, was second with a fruit weighing $3\frac{3}{4}$ lbs., and Mr. Jones, gardener to Lady Mill, Ramsey, third. In the class for any other variety Mr. J. Douglas, gardener to P. Whitburn, Esq., Ilford, was first with a very good *Smooth-leaved Cayenne* of $5\frac{1}{2}$ lbs., and Mr. Powey, gardener to the Rev. J. Thornycroft, Congleton, second with a well-ripened *Black Prince* of 6 lbs. The same variety, weighing $7\frac{1}{2}$ lbs. from Mr. A. Taylor, gardener to H. E. M. Ingram, Esq., Temple Newsam, was third.

GRAPES.—*Black Hamburgs* were almost without exception very good, though in some instances somewhat lacking in that deep colour which is so pleasing to the eye but not inseparable from excellent flavour. Mr. Meredith and Mr. Clement, East Barnet, were placed equal first with excellent bunches, those from Mr. Meredith being very perfect in colour. Mr. Allen, gardener to Capt. Glegg, Wiltington Hall, was second; and equal third prizes were awarded to Mr. Meads, gardener to R. Currie, Esq., Minley Manor, and Mr. Osborne, Finchley. Excellent bunches were exhibited in the same class by Mr. Turner, Mr. Miller, Mr. Wallis, Mr. Clement, and others. In *Black Prince* or *West's St. Peter's*, Mr. Meads and Mr. Hill, gardener to R. Sneyd, Esq., had, as usual, a close contest with the former variety, and an equal first prize was awarded to each; the bunches, however, though very fine, did not come up to the superb productions of the last and previous years. Mr. Allport was second with finely coloured bunches of *West's St. Peter's*; Mr. M. Henderson, gardener to Sir G. Beaumont, Bart., Cole Orton Hall, third with *Black Prince*. The same kind, but the bunches more resembling a *Hamburg* in their style of growth, was shown by Mr. Lynn.

Of other varieties there were several good bunches of *Blackland Sweetwater*, *Black and Grizzly Frontignan*, *Chasselas Musqué*, and excellent *Muscats* from Mr. Turner and Mr. Tansley, gardener to A. Moss, Esq., Chadwell Heath.

Awards—For *White Muscadine* or *Sweetwater*: first, Mr. Osborne; second, Mr. Hill; third, Mr. Bailey. For *Frontignans* or *Chasselas Musqué*: first, Mr. Allport; second, Mr. Bannerman, gardener to Lord Bagot, Rugley; third, Mr. M. Henderson. For any other variety: first, Mr. Turner; second, Mr. Tansley; third, Mr. Coles.

MELONS.—Of the *Green-fleshed* varieties the best were *Meredith's Hybrid*, *Queen Emma*, a seedling from it, and *Heckfield Hybrid*; and of *Scarlet-fleshed* *Scarlet Gem* and *Tegg's Hybrid Scarlet*.

Awards—For *Green-fleshed*: equal first, Mr. Sage, gardener to Earl Howe, and Mr. Derrinhouse; second, Mr. Carr. For *Scarlet-fleshed*: first, Mr. Tegg, gardener to the Duke of Newcastle, Clumber; second, Mr. Bailey.

PEACHES AND NECTARINES were not numerous, but for the most part good. The former chiefly consisted of Royal George and Grosse Mignonne; the latter of Violette Hative, Elruge, and Hunt's Tawny.

Awards—For Peaches: first, Mr. Taylor; second, Mr. Sage; equal third, Mr. Whittaker, gardener to Lord Crowe, and Mr. Tegg; fourth, Mr. Evans, gardener to C. N. Nowgate, Esq., M.P. For Nectarines: first, Mr. Turner; second, Mr. Lynn; third, Mr. Allen; equal fourth, Mr. Hill and Mr. Evans.

MISCELLANEOUS.—The remaining subjects were so few in number that they may all be included under this head, though for some classes were assigned. Of Cherries there were good dishes of May Duke from Messrs. Jackson, of Kingston, and Mr. Wilson, of Warwick. Black Tartarian and Frogmore Forcing, from an east wall, were also shown; and in the White class Governor Wood, pale yellow mottled with red, and Elton. Of Strawberries there were good dishes of Sir C. Napier, Sir J. Paxton, Empress Eugenie, Marguerite, and British Queen; and of Figs, fine fruit of the Castle Kennedy from Mr. Fowler of that place, and Brown Turkey from Mr. Jones. Good baskets of Black Hamburg Grapes came from Mr. Clements, Mr. M. Henderson, and Mr. Wallis; Citrons from Mr. Elliott, gardener to Lady Palmer, Leicester; and boxes of Peaches and Nectarines respectively from Mr. Allen, gardener to E. Hopwood, Esq., and Mr. Allen, gardener to Capt. Glegg. A brace of a large Cucumber, called Lancashire Witch, was shown by Mr. Morris, gardener to Col. Clifton.

Awards—For Black Cherries: first, Messrs. Jackson; second, Mr. Wilson; third, Mr. Lynn. For White: first, withheld; second, Mr. Wilson. For Strawberries: first Mr. McIndoo, gardener to Coles Child, Esq.; second, Mr. Turner; third, Mr. Johnson, gardener to the Marquis of Ailesbury. For Figs: first, Mr. Fowler; second, Mr. Jones.

FRAGMENTS ABOUT THE INTERNATIONAL HORTICULTURAL EXHIBITION.

BEDDING GERANIUMS.

"TEMPORARILY suspended business," was the ominous notice I saw on the doors of many an establishment lately, and I suppose it was infections, for I had fully made up my mind to give some further notes on the International last week; but many of our patient readers who know what travelling is, to be wearied and jaded with journeying, and with the excitement inseparable from seeing strange sights and places, will, I am sure, take as a sufficient reason for my silence the excuse that our floral contributor has "bolted." I am really anxious to say a few words upon this great display, because there was one department which seemed to me to be as generally attractive as any, and which manifested as many points of interest, and that was the large and varied display of bedding Geraniums. Every one is on the lookout for them—they suit every one's pocket and most people's taste; and hence to admire what was new, and wonder what we should come to next, was the occupation and talk of many a demented horticulturist; and, in truth, there was enough to excite admiration, whether one regarded the fine plants exhibited by some growers, or the striking novelties brought forward by others. As to the general merits of these plants, I still maintain my "idiosyncrasy," that the true Zonales (although many of them have no *zone* at all), are preferable to the Nosegays; and this I say notwithstanding the beautiful varieties I saw there, for it is just as these hybrid Nosegays gain more of the Zonale character and lose the Nosegay, that they become more attractive. Thus, that very fine flower Rebecca approaches in its form and size very much more the Zonale than any I have yet seen; and, by-and-by, I think we shall see this hybridisation so carried out, that the colours of the one section will be combined with the round form and large petals of the other.

By far the finest group of Zonales was contributed by Mr. Fraser, of Lea Bridge. It contained fine plants and well named of Emile Lienn, good salmon; Madame Werle; The Clipper, fine scarlet; Marie Virgo, Malakoff, Eucemie Mezzard, Mons. Barre, Lord of the Isles, fine; Mous. G. Natchet, and Rose Rendatler. The second collection was that of Mr. Lermotte, Finchley; the plants were not so large. The third was from Mr. Charles Turner. The only collection of Nosegay Geraniums was that of Mr. William Paul, Waltham Cross. It contained fine plants of Cybister, Amy Hogg, Rebecca, Glowworm, Crimson Queen, Dr. Hogg, Wood Nymph, Nosegay, Duchess, Scarlet Dwarf, Tiara, and Waltham Seedling. In Variegated Geraniums a beautiful collection was shown by Messrs. E. G. Henderson & Co., containing Silver Nosegay, Snowflake, Lady Callum, very beautiful; Queen of Queens, one of Mr. Bull's fine seedlings; Countess of Tyrconnell, Oriana Improved, Meteor, Mrs. Pollock, Rosette, Silver Cashion, and Beauty of Guestwick. Messrs. Fraser had a good collection also, containing Gold Pheasant, Italia Unita, Mountain of Snow, Yellow Belt, Fontainebleau, Mrs. Pollock, Argus, Variegated Nosegay, Glowworm, Golden Vase, and Flower of Spring. Messrs. Saltmarsh, who took the third place, had smaller but well-done plants of Variegated Nosegay, Mrs. Pollock, Burning Bush, Variegated Tom Thum, Mrs. Mildmay, Variegated Nosegay, Cloth of Gold, Alma, Bird of Paradise, Electric, and Countess. I think, however, that one may safely say that the chief interest connected with this part of the display was centered in the seedlings that were brought forward by several growers, conspicuous amongst whom were Messrs. F. & A. Smith, of

Dulwich; Messrs. E. G. Henderson & Co.; Messrs. Garaway, of Bristol; Saltmarsh, of Chelmsford; and Chater, of Baintree. These were mainly in the tricolor variegated class. Mr. Wm. Paul and others contributed also largely in the Zonale and Nosegay section. It is, indeed, hard to particularise where so many beautiful things were to be seen; but in Messrs. Smith's collection, Jetty Lucy, Souvenir de Sir Joseph Paxton, Aurora, L'Empereur, and Refulgans; these were all fine. Many others also were good, and I foresee the greatest difficulty will be, by-and-by, to select which are best to be grown. In Messrs. Henderson's collection, which was shown in a purple-colored case covered with plate glass, were Lady Callum, good; Lucy Grieve, bright, but a shy grower; Sophia Cusack, good. Messrs. Saltmarsh had their fine variety Meteor, in Mrs. Pollock's style, and Queen of the Fairies, a charming little white-variegated kind with a salmon flower having a white centre, looking almost like a variegated Henri Desjolis. Mr. Jabez Chater had a very fine seedling, Senior Wrangler, which in habit and colouring seemed to be all that could be desired. In Messrs. Garaway's set were Queen of Tricolors, good, and Princess Lichtenstein; while in the white tricolor section, Mr. Hally, of Blackheath, showed Sirius and Mirth. Mr. W. Paul was the chief contributor in seedling Zonale and Nosegays. Rebecca, of which I have already spoken, and Prince of Orange, seemed to be the best. Mr. Wm. Bull sent a very pretty variegated Ivy-leaf, called Silver Queen; and Messrs. Downie, Laird, & Laing contributed their fine pink-flowered variety, Wiltshire Lass. As I think over these, the instalments of yet greater numbers which will be brought forward from time to time, I seem to be bewildered at the notion, and although at present these variegated kinds are only sought after for their foliage, I believe that by-and-by the flowers, will form a very marked feature in them; and if we can get not only the scarlets, but the salmon, pinks, and whites amongst them, one cannot, I think, imagine anything more beautiful than a collection of such varieties would be.—D., Deal.

LIST OF THE PAPERS AND SUBJECTS PRESENTED TO THE BOTANICAL CONGRESS.*

MR. JAMES ANDERSON, Meadow Bank, Glasgow: Observations on the temperature of water, and its effects upon plant-cultivation.

Mr. Anderson considers that practical gardeners do not attach sufficient importance to the science of horticulture, but rely too much on routine, especially so with reference to the temperature of the air in plant-houses, and to that of the water supplied to the plants. He advocates the importance of employing water at least as warm as the air, or a little warmer, for watering tropical plants, especially Orchids.

M. ANONÉ, Paris: On landscape gardening and garden architecture in Paris from ancient times to the present, with remarks on the present style.

M. BAUMANN, Ghent:

1. Eulogy on English exhibitions.
2. Critical observations on Belgian exhibitions.
3. Reply to the advocates of the superiority of Belgian arboriculture.

M. A. BLYTT, Christiania: On the geographical distribution of plants in the Sognefjord, west coast of Norway.

M. BOEMER, Ghent: On the variegation and colour of leaves.

M. BOSSIN, Paris:

1. Is there any constant external botanical character by which it may be possible to tell at a glance what seedlings will produce double flowers, from those which only produce single ones, and if such exist what is that character?

2. To facilitate intercommunication between the natives of different countries, should Latin adjectives be employed to designate kitchen garden plants? Supposing the use of such adjectives to be considered desirable, how should they be adapted to generic names?

3. Is the Pear known as the Belle Angevine, Royale d'Angleterre, &c. [Uvedale's St. Germain], French, Belgian, or English? Are the date and place of its origin, and the name of its raiser known?

MR. W. BULL, Chelsea: On the relation of horticulture and botany to mankind in general.

MR. CARROLL, Glasnevin: On garden drainage.

The author, after alluding to the necessity for, and the advantage to be derived from cleansing cultivated ground, goes on to state that no adequate provision is made to guard against drains being choked or stopped, and, in many cases, rendered quite useless, and even mischievous, by the intrusion of the roots of plants, and the deposit of

* These abstracts are only intended to convey an idea of the contents and object of the several papers, and are not to be considered as complete. In a few instances they have been supplied by the authors themselves; in others they have been drawn up by the Committee; while in those cases where no such *resumé* is given, it is to be understood that the authors have not sent in their communications or their abstracts in time for publication.

oxide of iron, carbonate of lime, &c. The evil in question he proposes to remedy by laying a body of porous material beneath the drainage-pipes instead of above them; and this, because he has observed that roots always descend by preference to the bottom of any such porous substratum as they may come in contact with.

Professor DE CANDOLLE, Geneva: On a recent and very exact measurement of the diameter of the trunk of one of the gigantic Sequoias of California.

M. De Candolle in this paper gave the measurements of one of the huge specimens of Sequoia (Wellingtonia) of California—viz., that known as the Old Maid. This tree has been broken off by a storm at a height of 128 feet, its base cut across now serves as a dancing-floor. M. de la Rue has recently measured the diameter of this tree in the following way. A slip of paper was stretched across the diameter of the trunk, the annual rings being marked off with a pencil on the paper, according to the convenient method originally proposed by Augustin Pyramus De Candolle. This paper was exhibited by M. De Candolle, and the following details were given. The diameter at about the height of 6 English feet was 26 feet 5 inches English. The entire height of the tree, before it was broken by the wind, was approximately 350 feet. The number of rings was counted by M. de la Rue and his assistant, one going from the circumference towards the centre, the other in the opposite direction. The one counted 1233 rings, the other 1245, which were marked on the slip exhibited by M. De Candolle. The mean of the two observations, which is no doubt nearly correct, gives the tree an age of 1231 years, which is not an extraordinary one for trees, especially Conifers; there are, for instance, Yew trees which date back from the Christian Era. The Sequoias grow in a deep and rich soil, and their rate of growth appears to have been very uniform; thus on the slip it may be seen that at the age of 400-500 years, the annual rings were still thick, while in ordinary trees the layers become thin at from 80 to 120 years, according to the kind of tree and other circumstances. Specimens of the wood were also exhibited.

Professor CASPARY, Königsberg: On the change in the direction of the branches of woody plants caused by low degrees of temperature.

The author, in this paper, gives with much elaboration the result of his observations on the motion observed in the branches of trees in frosty weather. He shows that there is in winter a movement of the branches to the left-hand side, the amount of which is in direct proportion to the intensity of the frost. 2ndly. There is in many cases, in addition to the lateral motion, a vertical one from above downwards, also in proportion to the intensity of the frost. 3rdly. In other cases the vertical motion takes place in the opposite direction—that is, the branches move upwards as soon as frost sets in, and rise proportionately to the severity of the cold—e.g., *Acer Negundo*, &c. 4thly. In other woody plants the branches are observed to rise in mild weather, and to droop during severe frost—e.g., *Æsculus hippocastanum*, &c.

Major TREVOR CLARKE, Daventry: On a certain phenomenon of hybridism in the genus *Mathiola*.

Mr. B. CLARKE, London: On the floral envelopes of Lauraceæ.

The author regards the floral envelopes of Lauraceæ as double, consisting of a trimerous calyx and corolla, and supports his views by a reference to those of Laurus itself, the fourth sepal of which he considers to be internal, and belonging to the petaline series, the other two divisions of that series being converted into stamens. He refers to the near affinity of *Hernandia* (recognised by all authors from Jussieu downwards), and of *Gyrocarpea* (pointed out by Robert Brown, and adopted by all subsequent writers), and to the evident relation of the last-named family to Combrétacées (of which indeed Lindley regarded them as merely a section), and derives, from a comparison with all these plants, further arguments in support of the correctness of his notion. Evidences of near relationship are also deduced from the structure of their ovaries and the attachment of their ovules, and the author finally arrives at the conclusion that Lauraceæ are "Combrétacées, with a superior ovary and sepaloïd petals."

Dr. ALEXANDER DICKSON, Edinburgh: On the leaves of *Sciadopitys* and *Phyllocladus*.

Mr. W. EARLEY: On the preparatory formation of trained wall-fruit trees.

The writer sets forth that the present system of pruning trained trees in the nurseries is objectionable, on the ground that the too free use of the knife injures and often destroys the constitution of the tree when in a young state, and is one cause of wall-trees shrivelling and dying. It is also the cause of a too gross aftergrowth, and consequent unfruitfulness. He advocates, in place of the present system, summer pinching, which attains the end sought in less time, and produces a sounder tree, more favourable to removal.

Professor GOEPPERT, Breslau:

1. On the arrangement of Alpine Plants in our gardens.

The author condemns the indiscriminate planting, and total absence of order or arrangement of the alpine and arctic plants cultivated in our gardens, and considers that one object in our botanic gardens should be the illustration of botanical geography. About 450 of the flowering plants of Germany and Switzerland may be looked on

as truly alpine, and of these about two-thirds are grown in the Breslau Botanic Garden; some in pots, others planted out in a space of about a Prussian acre in extent, planted out amongst various kinds of stone and rock in eight groups, as shown in the accompanying photographs. The red snow, *Protococcus nivalis*, grows here in a hollow slab of granite. The plants are arranged in groups according to the levels at which they grow in their native habitats. In this way the relation of vegetation to altitude may be seen at a glance.

2. Palæontology and our botanic gardens.

The author draws attention to the intimate connection between recent and fossil botany, and gives an account of the steps he has taken in the Breslau Botanic Garden to illustrate the latter, by forming a model section of the coal formation, with its characteristic plants. In a similar way the enormous trunk of the *Finites Protolarix*, discovered and described by the author, serves as a representative of the tertiary formation. The paper is accompanied with photographs.

Mr. S. HINBERG, London: On the naming of plants.

"The importance of botanical nomenclature to science, art, and literature.—Classical origin of many of the names of plants.—Names of plants divided into two classes, natural and artificial.—Prevalence of artificial names at the present time; objections to them.—Proposed revision of botanical lists.—Proposed establishment of a board of botanical nomenclature."

Dr. HILDEBRAND, Bonn: On the necessity of insect agency in the fertilisation of *Corydalis cava*.

Dr. Hildebrand concludes from his experiments, that the flowers of *Corydalis cava*, when protected from insects, and thus acted on by their own pollen, form no capsules. 2nd. That fruit is very seldom formed when the flowers of the same raceme are crossed with each other. 3rd. By the crossing of flowers on different individual plants alone, is perfect fertilisation insured.

Mr. J. E. HOWARD, London: Observations on the present state of our knowledge of the species of *Chinchona*.

"The chief cause of the confusion in our knowledge of the *Chinchona* has been the tendency to systematise without a full acquaintance with the details. I entirely disbelieve in all the so-called typical forms, and in all the attempts to classify and arrange them. The very best of these attempts seems to me to break down (as shown by Karsten), even as regards the exact limits of the genus itself, which blends by intermediate links with the other *Chinchonaceæ* genera. I wish to direct especial attention to the spelling of the name of the genus, whether as *Cinchona* or as *Chinchona*; also to the name of an allied genus, whether as *Cascarilla* or as *Ladnbergia*. Nothing would tend so well to settle these questions as the free expression of opinion at a Botanical Congress. I would also point attention to the necessity of considering some as markedly distinct forms rather than as mere varieties having sub-varieties, until all ends in confusion. If this be admitted, the *Chinchona pitayensis*, *C. lanceifolia*, *C. purpurea*, *C. erythroderma*, *C. Pelletierana*, &c., would take their legitimate place; and I propose, by the side of these, to place the *C. Bonplandiana* vars. *colorata* and *latea*, as representing a distinct form of the Loja bark. I would confine the name *Chinchona Condaminia* to the real *Quina primitiva* (if the having cured the Countess of Chinchon entitles it to this appellation), abolishing Pavon's barbarous name *Chahnarguera*. I have attempted to reduce into practical use Karsten's varieties of *C. lanceifolia*—viz., *obtusifolia*, *obovata*, *trunilata*? *angustifolia*? and *Almaguerensis*? The last three I venture myself to suggest. The varieties of *Chinchona Calisaya* I do not venture to do more than allude to, as, I hope, Dr. Weddell may farther elucidate this subject. In conclusion, I will express my opinion that every well-defined region of the Andes has its own prevalent and characteristic *Chinchonas*, which are incapable of being reduced to any one typical form; and I believe that no one species has been clearly proved to prevail unchanged from end to end of the *Chinchonaceæ* region; and I think that the plants which resemble each other in distant parts will be found analogous rather than identical."

Mr. Howard has succeeded in obtaining quinine from the bark of *C. officinalis*, which he cultivated in his own stove, and procured very nearly as much quinine as is yielded by bark of the same age in its native country. This is probably the first time that quinine has been extracted from bark grown in Europe.

Mr. H. HOWLETT: On night-covering and shading of plant and forcing-houses.

The author's object is to combine shading with night covering by means of one contrivance fitted to the roof. He points out the necessity for the former, and the great advantages to be derived from the latter; and suggests that both may be secured, by fitting on the roof a series of louvre boards moved by levers. The suggestion is offered as affording ground for discussion, but has not been practically tested.

M. VAN HULLE, Ghent: Rational method of pruning.

The writer assumes that the fruits produced in England are abundant, but small, and usually produced by trees left to their natural growth, owing to which they are neither so handsome in form nor so productive as they might be. Their productiveness in England, such as it is, is due rather to the skill displayed and cost incurred in managing the ground than on the management of the trees. The

writer assumes that the English prune their trees to make them grow, without properly considering regularity of form or size of fruit.

He recommends pruning to obtain symmetrical trees and large fruit, by recognising the character of the different branches; as, for instance, whether fruit-bearing or wood-bearing, and treating them accordingly, in opposition to the system of treating all alike, which he calls the old system, and speaks of it rather as "pruning without system." The old plan leaves nature to form wood or fruit branches at will; he would so control nature, as to form either at pleasure.

Professor KARL KOCH, Berlin: Some propositions with respect to systematic botany.

Three especial sources of difficulty beset the systematic botanist of our day. 1st. The confused nomenclature. 2nd. The scattered literature. 3rd. The distribution of great numbers of plants by nurserymen under fanciful names. One man can do but very little to remove these obstacles, but a Congress of botanists and horticulturists will be better able to effect the necessary changes and improvements.

Professor Koch proposes to obviate the confused synonymy by retaining the specific name first given; but as regards the generic name, to place that which recent investigation has adopted first, and the one by which it was first described afterwards, in a parenthesis. If an author's name be given, it should be that of him who first described the plant. Our nomenclature begins with Linnaeus, and hence all botanists prior to him are to be disregarded. Linnaeus, for instance, describes *Ornithogalum luteum*, but Salisbury discovered characters of sufficient importance in this plant to justify him in making a new genus, *Gagea*. Our plants should therefore be called *Gagea lutea* (*Ornithogalum*) Linn.

Secondly, the scattered literature. Botanists now-a-days write in German, French, English, Italian, &c., and in a large number of different periodicals, so that it becomes very difficult, or next to impossible, for a man to make himself thoroughly acquainted with the literature of the subject. Professor Koch proposes, therefore, to select a number of botanists from various countries to examine and collate the separate publications of their several countries. A general editor is to be appointed in a European town where there is a good library, and all extracts are to be sent to him at that place. The general editor is to arrange these extracts scientifically, and to publish them in the Latin language.

Thirdly, as to the importation of plants by nurserymen. No disadvantage would ensue if the horticulturist were to adopt a provisional name in the first instance, and then apply to a botanist for the correct name, which could then be published; but in adopting this plan, there are two difficulties to be encountered. Gardeners would seldom take the trouble to change the provisional for the scientific name; and they would not always know which botanists studied particular families, or would not venture to trouble them. This ought, therefore, to be the task of a Botanic-Horticultural Congress.

Fourthly, many botanists have already devoted themselves to particular families, and it is to be desired that others should do the same. Horticulturists might then apply to these botanists for information, &c. Professor Koch then points out several instances where he has succeeded in carrying out the proposed reforms.

Professor KICKX, Ghent: On the physiology of Cryptogamic plants.

M. KRELAGH, Haarlem: On the names of garden varieties and their confused synonymy, with special reference to bulbous and tuberous rooted plants.

Mr. THOMAS LAXTON, Stamford: On the variations effected by crossing on the colour and character of the seeds of Peas.

The specimens exhibited were selected for the purpose of illustrating the variations produced by crossing, in the colour and character of the seed of Peas, in the second and succeeding generations.

The results of experiments in crossing the Pea tend to show that the colour of the immediate offspring seed or second generation, sometimes follows that of the female parent, is sometimes intermediate between that and the male parent, and sometimes distinct from both; and although at times it partakes of the colour of the male, it has not been ascertained by the experimenter ever to follow the exact colour of the male parent. In shape, the seed frequently has an intermediate character, but as often follows that of either parent. In the second generation, in a single pod, the result of a cross of Peas, different in shape and colour, the seeds therein are sometimes all intermediate, sometimes represent either or both parents in shape or colour, and sometimes both colours and characters with their intermediates appear. The results also appear to show that the third generation, or seed produced from the second generation, or immediate offspring of a cross, frequently varies from its parent in a limited manner—usually in one direction only, but that the fourth generation produces numerous and wider variations; the seed often reverting back partly to the colour and character of its ancestors of the first generation, partly partaking of the various intermediate colours and characters, and partly sporting distinctly from any of its ancestry. These sports appear to become fixed and permanent in the next and succeeding generations; and the tendency to revert and sport thenceforth seems to become checked if not determined.

The experiments also tend to show that the height of the plant is singularly influenced by crossing; a cross between two dwarf Peas

commonly producing some dwarf and some tall, but on the other hand, a cross between two tall Peas does not exhibit a tendency to diminution in height.

No perceptible difference appears to result from reversing the parents and applying the pollen of the female to the variety previously employed as the male flower.

Professor LECOQ, Clermont Ferrand:

1. On the cultivation of *Colchicum byzantinum*.

A description of the plant, and of the method of cultivating it, is here given. The author recommends it for use in greenhouses and living-rooms, its corals being concealed by *Lycopodium*.

2. On the migration of mountain plants.

The object of the author is to show that the mountains of Auvergne have received their Alpine plants by the agency of birds and of wind, and not by a gradual migration during a supposed glacial period, the existence of which he denies altogether.

This district, he says, was, at the tertiary period, a vast plateau, with a mean altitude of 8-900 feet. Volcanic eruptions then inundated it, altered its soil and climate, and raised it in some places 1000 metres. "Then," says he, "clouds began to settle on the heights and snow to accumulate, and innumerable streams flowed from its icy summits, and by their murmurs seemed to call to a foreign vegetation to come to and enjoy these happy conditions. The hospitable appeal was heard." &c.

The boreal species, with which alone we are concerned, and a list of which, about 104 in number, he gives us, could not, he says, have arrived till after the volcanic elevation of the district, and they could only have come from the Alps, the Pyrenees, Lapland, or the mountains of Grenada. But as all these species are either Alpine or Pyrenean, with the one solitary exception of the *Arabis cehennensis*, we may assume that these two great chains were the home from which they came as colonists to France.

The intermediate country is low and flat, and afforded them no resting place; Darwin's theory of their progress by means of a glacial period he rejects; and concludes that they must therefore have been transported thither through the air, and mainly by birds of passage and violent storms of wind.

M. LAHAYE, Paris: On the preservation of fruits.

The author says it is impossible to preserve fruits out of their season if the trees which produce them are in bad health or condition.

M. MAS, Bourg: On the method to be followed in endeavouring to obtain new varieties of fruits.

Dr. MASTERS, London: Double flowers, &c.

Dr. DAVID MOORE and Mr. A. G. MORE, Glasnevin: On the climate, flora, and crops of Ireland.

The authors remark upon the well-known humidity of the climate, and the singularly slight difference that there is between the summer and winter temperature; a difference that at Dublin is only 17½° Fahr., and on the west coast as small as 14°. Indeed, that of winter, they say, is as high as though the island lay 15° nearer the equator. Hence the peculiarity of the Irish flora, of which they give a list of the more interesting species, and an accompanying map to show their geographical distribution. The humidity of the climate and its low summer temperature they find to be unfavourable to the ripening of fruit and wheat, but such as to render Ireland the country of all Europe the best fitted for green crops and cattle-grazing.

Appended are some interesting returns sent in by gardeners in the counties of Cork, Kerry, Galway, Mayo, Sligo, and Fermanagh, in answers to queries as to their success with fruit trees, and half hardy shrubs and flowers. These returns agree in showing that the climate of the southern and western counties is ill adapted to the growth of fruit, but favourable to that of evergreens.

(To be continued.)

NOTES ON THE WAY TO THE HOLY SEPULCHRE.—No. 2.

It is a strange transition to pass from the rude Alexandrian vessel, shipwrecked in St. Paul's Bay at Melita, to the grand steamers of the Peninsular and Oriental Company, carrying out their living freight bent on business or pleasure. A greater transition still it is to turn from the low white coast which first greeted the Apostle's eyes to the harbour of Valetta, with its tremendous fortifications bristling with cannon, its wharves and quays, where representatives of every nation under heaven are congregated together, jostling each other in that weary struggle for "daily bread" that to the people of the nineteenth century seems to mean anything rather than the "food convenient for them."

Amongst this motley assemblage a few months ago was the tourist whose route I intend to follow in these notes, and whose collection of plants, together with a journal, has very

obligingly been placed at my disposal. Added to this there will be other material, true and lifelike, as every "note" should be that is struck on the sacred way that leads us to the Holy Sepulchre. Each flower we gather has an interest belonging to itself alone. We can cull them with no careless hand; for although they may be strewn around us in bounteous munificence, the thought will come that He who gives them all to us found an earthly grave at our "wicked hands," and that the only wreath we offered back to Him was the "crown of thorns" that encircled His bleeding brow on Calvary.

Following the route I have intimated, we may yet linger for a little while with the Apostle St. Paul as, sailing for Rome, he landed and remained three days at Syracuse in Sicily. After noting this visit, shall we be astonished to read in the ancient history of the island that "Christianity spread early into Sicily, and that a persecution of the Christians took place under Nero," the very Caesar to whom St. Paul had appealed, and to whose "judgment seat" he was journeying when he was shipwrecked at Malta? Thus regarding Sicily it becomes like a faint reflection of the Holy Land; and as we coast its rocky shores and watch for the first glimpse of Mount Etna, which rises upwards of ten thousand feet above the sea level, our thoughts turn once and again to those bygone days, which have left their impress upon the earth as fixed and sure as is that of the "everlasting hills."

Sometimes at daybreak the old mountain will show itself forth in all its glory, occasionally puffing out a volume of smoke as a sort of credential of what is going on within. The entire group of Etna occupies about ninety miles in circumference, and the sides of the mountains are covered with forests of Oak, Beech, Maple, Birch, Fir, and magnificent Chestnut trees, varied by occasional streams of lava, which have run down even to the seaport of Catania, carrying devastation and misery along with them.

The Wheat in the province of Catania is very bad; and corn is brought from Egypt and sold at a cheaper rate than that which is of home growth, owing to the difficulty of land carriage in so mountainous a region, while Indian corn, together with barley and beans, is converted into bread.

High up, on the mountain near Zafarana, there are extensive vineyards, from which delicious wines are made, Bronte, or, as it is also called, Etna wine, being largely exported. The white wines of Marsala and Catania, with the muscat of Syracuse, have almost a world-wide name. Besides the vineyards on Etna there are orchards of Lemons and Oranges, which are both plentiful and fine, Sicily being famed for its essences of Lemon, Citron, Orange, Aniseed, Lavender, Rosemary, and Bergamot.

From such a land of flowers those collected during one short visit must necessarily form but a very small proportion; and yet, gathered as they were in spring, they speak as heralds of something still greater being at hand. The most noticeable of the spring flowers are the Cyclamens, which grow in large masses, their darkly veined leaves contrasting so beautifully with their delicate bloom. The Cyclamen repandum is found near Messina. There also grows the *Mathiola trienspidata*, and there the *Erica vagans*, which is found in our own Cornish land. Another familiar friend, but grown considerably larger by Sicilian diet, is the *Trichonema bulbocodium*. This tiny Crocus-like plant grows plentifully by the seashore between Dawlish and Starcross in Devonshire, and also in Jersey; but the Sicilian specimen is brighter in colouring, and at least four times the size of the English plant. I should like to claim acquaintance with yet one other Sicilian flower—the *Phlomis fruticosa*, with its soft glaucous leaves and yellow whorl of blossoms, which I have found growing wild in Devonshire. But alas! I am bound to confess that, on mentioning my mind to a botanist, I was met with "escaped from a garden," and with this dictum I had to be content.

Allied to the *Phlomis* is the *Teucrium fruticosum*, which is commonly to be met with, as is also the *Viola tricolor*? which I have so often gathered in country walks both in England and Scotland. Of the wild *Geraniums*, *G. molle* is the only specimen I have from Sicily, while Dr. Deakin gives four—*dissectum*, *molle*, *Robertianum*, and *rotundifolium*, as growing on the Colosseum alone.

Specimens of *Psoralea bituminosa*, *Lathyrus ochrus*, *Centranthus calcitrapa*, *Passerina*, *Euphorbia dendroides*, and *Orchis undulatifolia*, together with a pretty *Senecio* and *Linaris*, were sent to me. There was but one solitary Fern—*Polypodium vulgare* (var. *acutum*?) which brought back to

my memory the plant I found on the Colosseum, where it grows for the most part high up and safe from the merciless grasp of Fern-collectors, who show no pity to bare ruins if only they can add to their collection.

Amongst the Sicilian plants, and having written upon it the word "introduced," was a lovely spray of *Bougainvillea spectabilis*, its purplish rose-coloured bracts answering for flowers, the real flower being very insignificant. I have lately seen a fine specimen of this beautiful plant in full bloom in a garden in Devonshire; and shortly afterwards I saw a spray which had arrived in a letter from India, having on it this notice, "The *Bougainvillea* grows very commonly here." In Madeira the plant grows profusely trailing up the houses, and its colouring is rich and vivid; but the same species introduced into the Cape de Verdes is still more vivid in colouring, showing plainly the intensifying power of the sun's rays when brought to bear on colours predisposed to receive them. It is not long since it was supposed almost an impossibility to flower the *Bougainvillea* in England. It is pleasant to know that this horticultural difficulty has passed away.

But I must return to the mountains and valleys of Sicily, so rich in natural productions, where the Olive tree gives its olive oil, the Carob its sustenance for cattle, the *Ornus* its manna; while the products of these trees, together with Rice, Pistachia nuts, Walnuts, dried Figs, Almonds, honey, wax, gum, soda, and cotton are exported in great quantities. On one of the Trapani Islands—Maretimo—wild Thyme (*Thymus fruticosus*?) grows in such quantities that it makes the district like one vast bee-hive, so many bees are attracted to and nourished upon it. The liquorice juice that is used for brewing in England is made at Palermo, while Messina is a great mart for a common kind of silk.

Sicily abounds in magnificent scenery—mountain, rock, and ocean appearing and disappearing in mingled grandeur and beauty; and to natural objects are added ruins of Greek and Roman architecture, amongst the most remarkable of which is the vast theatre erected near the town of Taormina, and said to have been capable of holding forty thousand people. The seats are partly formed by the hillside, and command the most glorious views, on the one side of the Straits of Messina and Italy, and on the other of Etna and the Mediterranean.

The drive from Catania to Taormina, inland by Zafarana, forms a beautiful introduction to the yet grander scenes that await the traveller as he winds up the steep hill to the theatre, and then onwards and upwards to the ancient fortification called La Mola, the ascent to which is precipitous in the extreme, catching first glimpses and then bolder revelations of glory. Beneath his feet is a robe of many-coloured flowers; lifting up his eyes they rest on mountains glittering with snow, while the vault of heaven is one impenetrable sea of blue. The road from Taormina to Messina is hewn out of the cliffs overhanging the seashore, and commands an ever-varied succession of sea views.

From this land of beauty and plenty we must sail away to a far different scene, to a dreary, monotonous old town of Egypt, where the narrow streets rejoice in alternate changes between mud and dust, where good water is scarce, and vegetation—as Englishmen count vegetation—a thing to dream of, but never to be realised. Yet what varied associations does the very name of Alexandria recall! What visions of regal splendour when it was the residence of the Ptolemies! What dreams of learning and scientific research during the collecting together of that vast library, which was said at one time to contain 700,000 unprinted volumes. It was great in splendour, for we read of it as being the rival of Rome; great in commerce, for it succeeded Tyre in commercial importance; great in learning, for its library and schools were renowned all over the world. We are not surprised to find that Christianity took an early and firm hold in Alexandria, for its great library contained many a copy of the Scriptures, and its schools many an eloquent "Apollos mighty in the Scriptures," and who, by the very persuasiveness of intellect "mightily convinced the Jews, and that publicly, showing by the Scriptures that Jesus was Christ." We find Alexandrians amongst those who disputed with Stephen, so that we may infer that Christianity was not blindly accepted at Alexandria, but rather that it was the deliberate choice of men famed throughout the world for their intellectual capacities. That the choice was not made without some resistance from old prejudices we find from the fact of the Alexandrians, when not able to resist St. Stephen's wisdom, having had recourse to the common eastern practice of suborning men to give lying witness against him.

Alexandria does not seem to possess many natural advantages. Its shores are bordered with reefs; its soil, for the most part, a mixture of sand and rock. The town has no fresh water, but there are huge cisterns filled partly by rain and partly by water from the Nile; during the present century more than two hundred of these tanks were still in use. There are Fig trees and Palms, and in the gardens there are Mandarin Oranges, while agriculturists are doing what they can to bring the land under cultivation. Some wild flowers grow by the sea-shore, amongst them the small lilac *Mathiola oxyceras* and the *Anchusa strigosa*, which, but for its hue of bright blue, would remind one of the *Daphne encourum*. On the calcareous rocks by the shore at Rambla, about five miles from Alexandria, there grows a very small variety (?) of *Adiantum capillus-Veneris*; it is compact and neat-looking, and hardly appears to be of the same species as the common *A. capillus-Veneris*, which was gathered by a garden fountain in Alexandria on the same day. But the prettiest of all the wild flowers growing by that far-off shore is the *Doryenium argenteum*, the leaf and petals being like silver hair, the blossom yellow. Besides these there are the *Ornithogalum (exsepium?)*, the *Ononisatrix*, *Geranium molle*, and the *Buscus hypophyllum*. This last I had never before seen, and its tiny leaf growing out of the large leaf's heart and concealing the little flower beneath its sheltering fold, rendered it very interesting. There is yet one more wild flower to be mentioned, a strange-looking *Orobanche*, said by the Arabs to be very destructive to Bean crops.

I cannot leave Alexandria without a passing recognition of the two vast granite obelisks, which once formed the entrance to Cæsar's palace, but which are now known to us as "Cleopatra's Needles." One of these obelisks is still standing, and measures nearly 80 feet from the ground.—*FILIX-FEMINA.*

NEW BOOK.

Pinacæ: being a Handbook of the Firs and Pines. By SENLIS. London: Hatchard & Co.

Among the characteristics of old age we too often find a proneness to egotism, and it is not absent from the author of the volume before us; moreover, it appears in the worst of combinations, for it is egotism united to a proneness to depreciate other labourers in the same field. Thus "Senlis" ventures to publish this as his opinion: "The laudable attempts of most modern writers [on Firs and Pines] to remove obscurity have, in good sooth, only added to its shade." We need not ask him if he remembered Gordon's "Pinetum" when he wrote that sentence, for every page of "Pinacæ" shows that he was familiar with it; but we may observe, for he probably does not know, that there is a splendid work on Conifers now publishing by Messrs. Lawson.

We pass by all the "senility" manifest in the attempt to alter the classification and nomenclature, and the sneers at "theoretical botanists" and "literary pedants;" and we pause over the better, because the really useful, portion of the volume—we mean the information relative to the qualities of the timber produced by various species, their degrees of hardness, the soils they prefer, and such like practical knowledge. One extract will suffice to show this:—

"*ABIES DOUGLASHI* (Douglas's Columbian Fir).—This Fir is one of the most distinct, beautiful, and valuable ever introduced into Britain. It is thoroughly hardy, sound in constitution, of large dimensions, and very rapid in its growth; not particularly fastidious as to soil or situation, provided always the soil be in a sweet and healthy condition, and the subsoil cool and porous; for even now we have it growing, nay luxuriating, alike in the forests and parks of England, in the alluvial vales and humid clime of Hibernia, in the romantic glens and mountain dells of old Scotland, and in the debris of the slate rocks of Wales; and in its native habitats in the north-west it is equally as accommodating, for it is to be found on the highest peaks of the Rocky Mountains, a knarled bush about a yard high, while along the river's banks, and in the Columbian valleys, and at the mountain bases, it produces trunks of timber 200 feet in length and 10 feet in diameter at base. But much larger logs have been obtained from it when grown under very favourable conditions, for the tree from which the specimens of its wood were exhibited at our International Exhibition (1862), in the British Columbian Court, was over 300 feet in height; and, judging from its concentric ring-growth, its age was computed as approximating to a dozen-and-a-half score years. Amongst the specimens shown of its converted timber were a six-foot diameter of a horizontal section, as sound at its circumference as at its centre. The heavy planks, quartering, and flooring, were, indeed, admirable examples of valuable timber; and the split pales and shingles most clearly proved the fact,

that for ease in splitting, freedom from loss in the process, and less loss of strength in proportion to the dimensions split, if for such a purpose it has equals, it has indeed but few superiors. In common parlance it may be said to lend like a ribbon; and this every one engaged in the growth of timber, and more particularly those who have to convert it, will admit is a most valuable quality in a good and generally useful wood.

"Its timber may truly be termed first-class, A1; being, as it is, fine-grained, elastic, heavy, strong, free from knots, easily wrought, and capable of receiving a high polish; not very resinous, yet very durable, not subject to warp or splinter; and its only defect is that in trees which may be felled ere they have become aged and thoroughly matured, or have stopped growing, as we phrase it, it will be found that about one-third of its outer or circumference wood is more white, porous, and tough, and consequently less durable; while about two-thirds of its diameter, the centre or spine wood, is reddish in colour and most excellent in quality. Our best recommendation of this Fir is to state the fact that we are now cultivating and planting it in thousands annually, as a general forest tree; confident it will never disappoint us, although the opinion we have formed of it is indeed a high one. As an ornamental tree it only requires to be seen to be appreciated, and much more extensively planted, both for use and beauty, whether for profit or pleasure."

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

EULOPHIA VIRENS (Greenish Eulophia).—*Nat. ord.*, Orchidaceæ. *Lin.*, Gynandria Monandria. Native of the Neigherry Hills and Ceylon. Flowers greenish yellow with slight purplish streaks, not at all showy.—(*Bot. Mag.*, t. 5579.)

SCILLA COOPERI (Cooper's Squill).—*Nat. ord.*, Liliacæ. *Lin.*, Hexandria Monogynia. Native of the Cape of Good Hope. Flowers purple.—(*Ibid.*, t. 5580.)

CYPRINUS LAWSONIANA (Lawson's Cypress).—*Nat. ord.*, Conifere. *Lin.*, Monœcia Monandria. Native of valleys in the mountains of North California.—(*Ibid.*, t. 5581.)

WARSEWIZELLA VELATA (Veiled Warszewizella).—*Nat. ord.*, Orchidaceæ. *Lin.*, Gynandria Monandria. Requires only a moderately warm house and shading. Introduced by Messrs. Low & Co., Clapton Nurseries, Native of New Grenada. Flowers yellowish white, lip edged with lilac; fragrant.—(*Ibid.*, t. 5582.)

BEGONIA GERANIODES (Geranium-leaved Begonia).—*Nat. ord.*, Begoniaceæ. *Lin.*, Monœcia Polyandria. Imported from Port Natal by Messrs. Backhouse, York. Small species. Flowers white.—(*Ibid.*, t. 5583.)

MYRSIPHYLLUM ASTARAOIDES (Asparagus-leaved Myrsiphyllum).—*Nat. ord.*, Liliacæ. *Lin.*, Hexandria Monogynia. Introduced by the Duchess of Beaufort in 1702. Native of Cape of Good Hope. Flowers pearly white, tinged outside with green.—(*Ibid.*, t. 5584.)

TROPEOLUMS.—*Beauty*, sulphur-yellow, with crimson spot. *Attraction*, orange, with crimson spot. Exhibited by Mr. Williams, Fortis Green Nursery.—(*Floral Mag.*, pl. 293.)

ONTOGLOSSUM CERVANTESII.—Native of Mexico. Flowers pinkish white, marked with lines in broken circles.—(*Ibid.*, pl. 294.)

CAMELLIA.—*Nonpareil*, pale rose colour, regularly striped with dark rose. Brought out by Mr. W. Bull, Chelsea.—(*Ibid.*, pl. 295.)

KERRIA JAPONICA VARIEGATA.—Flowers single, yellow; leaves with broad white margin. Introduced by Mr. C. Turner, Slough.—(*Ibid.*, pl. 296.)

AURICULAS.—*Grm.*, shaded purple with yellow paste. *King of the Crimson*, shaded crimson with yellow paste. Introduced by Mr. C. Turner, Slough.—(*Florist and Pomologist*, v., 113.)

A PEEP AT THE WOODS IN ODD PLACES.—No. 6.

CUBA.

It was on a beautiful sunny day about noon that the passengers on board of a large screw-steamer sighted the coast of the lovely island of Cuba. The vessel was one of a line trading between Liverpool, Havana, and New Orleans. The passengers were, as is generally the case, of various nations and various interests, comprising British, French, Germans, Spaniards, Mexicans, and Americans (North and South), but chiefly of Southern tendency, or, as it would now jokingly be said, of Southern persuasion. I must not, however, digress, for I am keeping all the passengers standing still whilst I explain their nationalities.

As I have mentioned, Cuba was sighted, but we had what sailors term a dead head-wind; and as we were a long way from the harbour of Havanna, it was nightfall before we passed the Moro Castle at the entrance, and, therefore, in accordance with the rules of the port, we were compelled to drop anchor for the night at the entrance abreast of the hulk—that is, a worn-out old tub, without masts, which does duty as a guard ship. Here we remained for the best of all reasons—namely, because the authorities would not allow us to proceed before morning; but we were not without amusement, as we had several good singers on board, and they made a very merry night of it. Most of the passengers were leaving us at the Havanna, and they seemed determined to take poor General Wolfe's advice, and sing with him, as he did on the night before the battle of Quebec—

"Why stands the glass around?
For shame! Ye take no care, my boys.
Why stands the glass around?
Let wine and mirth abound."

Or, to act in accordance with the words of that exquisitely plaintive song, "The Deserter's Meditation"—

"If sadly thinking, and spirits sinking,
Could more than drinking my grief forego?
Then for that reason, and for a season,
Let us be merry before we go."

The night was brilliant, warm, and pleasant; and as the melodious tones of several rich and powerful voices, sometimes in unison, at others joining in parts, were borne away before a gentle breeze, they were thrown back, mellowed and reiterated, from the high rocks and headlands around; so that, what between the gentle ripple of the water of the bay, the striking beauty of the shores of which were dimly perceptible by the soft doubtful light of a young moon, aided in her endeavours to illuminate by thousands of stars—all this, taken in conjunction with a thorough harmony of feeling amongst those present, and a delicious balmy flower-scented air, made the scene one of those of which the remembrance cannot be forgotten in a lifetime.

The night being gone and the morning come, our forced delay was ended; so we Love anchor, and proceeded on our way to our wharf, it being somewhere about a mile farther up the bay, which I may here notice is one of the greatest beauty. Having at length moored or made fast alongside the jetty, I, in company with three of the gentlemen passengers, started to walk along the shore, or rather side of the hill, on the opposite side of the harbour to that on which the city stands, being that on which our wharf was situated.

The heat was intense, yet still I enjoyed the short ramble of about a mile very greatly, since, though so late in the year, some of the wild flowers were most beautiful. One attracted my attention in particular, it was a small flower of the *Convolvulus* tribe, pure white on the external part of the corolla, and most delicately tinted with pink internally, deepening in shade towards the centre, the flower itself at once catching the eye, nestling, as it did in clusters, amongst the deep, dark, shining green leaves of its elegant intertwining tendrils; the plant growing in great luxuriance and in large patches, but so closely were the sprays interwoven, that it was difficult to pluck one of any length without damaging it. This plant, or one of the same genus, and very similar to it, is known in the southern portion of the United States of America by the pretty soubriquet of "Morning Glory," on account of its opening and displaying its full beauty in the morning, whilst it closes in the afternoon and evening. Another flower which attracted my notice was a most exquisite yellow *Cistus*, the beauty of the foliage of which could only be equalled by the brilliancy of its petals, which, from their colour, forcibly recalled to my mind a tale I have often heard of an old servant of my grandmother who was promised a new gown, and when asked what colour she would prefer, remarked that she did not like showy colours, but she should like a bit of good plain yellow; and if the hue of her dress at all corresponded with that of this lovely flower, although I am afraid I could not agree with her in not considering it showy, still I must acknowledge that I should very greatly have admired its hue, especially had it been toned down in brilliancy, as it was in this plant, by the delicate tinge of pale green leaves.

The next flower that I noticed was a bright scarlet Broom; then a species of *Heliotrope*, which, though very similar in appearance, was not that sweet-scented flower so justly prized by us, and which children delight to call "Cherry-pie;" next was a pure white flower, one of the *Umbelliferae*, and, of course, from its position on a dry hillside, an aromatic, but not poison-

ous. All these were growing in the rankest luxuriance, interspersed with *Cacti*, many of them of very large size, and bearing most formidable spines of great length and acute sharpness, as one of my companions found to his sorrow; for in walking up the hill his foot slipped, and in saving himself from falling he struck his arm rather violently against a large plant of this description, the thorns of which, to teach him better manners and a proper amount of respect to the family of the *Cacti*, ran through his clothing, and deeply into his arm. In a few minutes he complained of great pain, and on baring his arm he showed me half a dozen pretty deep punctures all bleeding tolerably freely, and likewise a portion of a spine broken off into the flesh, which, having extracted for him, I found of the comfortable length of more than an inch. The wounded part swelled a good deal, but soon recovered under proper treatment.

The *Aloe* again here shows itself, and of all sizes from the pygmy with leaves scarcely longer than one's finger to the giant, each leaf of which will measure from 8 to 10 feet or more, and armed at the apex with an awful spike, and having its edges serrated somewhat after the manner of a shark's teeth.

Now, imagine to yourself all these beautiful plants, with here and there a few *Cocoa-nut Palms* singly or in clumps towering above all the rest, and spreading abroad their long, feathery, elegantly drooping leaves, growing on a rapidly rising hillside, with a bright semi-tropical sun pouring its clear rays down upon this really lovely spot, where not a breath of air was to be felt, and even *Zephyr* seemed asleep, and some notion may be formed of the amount of comfort we experienced as, just having arrived from the cool breezes of the sea, we slowly mounted the hillside, for road it cannot be called, that leads to *Castle Blanco*.

Castle Blanco is a small village or hamlet chiefly inhabited by poor creoles and Chinese, with a large mixture of negroes, who are employed in coaling the steamers which lie at the adjacent wharves. The appearance of this place is not prepossessing, for it presents to view all the mixture of squalor and miserable pretension common to all the Spanish and Portuguese colonies I have ever visited or read of—viz., gross superstition and rank blasphemy; dirt and discomfort, verandahs and mud floors, shaky doors and trembling wooden steps; wretched, untidy, half-breed women; filthy, unkempt, nearly, often entirely, nude children; and decidedly last, though not least, lazy, scowling, truculent men, whose whole life seems made up of *Water Melons*, *cigarritos*, low gambling, and loitering; gossip and scandal being, apparently, too great exertion for them.

Another noticeable species of animal to be found here I must not pass over without some remark—I refer to dogs, for the amount of canine creation found here is perfectly marvellous; but do not imagine that the dog aristocracy demean themselves by appearing here, for they would be out of place, but mongrels of every description have their representatives in this dog assembly, from the mongrel Cuban bloodhound, mangy and covered with scars, to the mongrel little white curly *Havanna poodle*, the true breed of which will often sell for as much as five ounces—that is, about £18 sterling.

Having passed through this delectable abode of dogs and of men, we at length reached the quay, and at once looked out for a boat to ferry us over the harbour, and after some bargaining we agreed with a sturdy little creole Spaniard to land us on the *Havanna* side for half a dollar, and accordingly, entering a queer small tub of a boat, with an awning over the after-part, the shade of which was very grateful, although it was then December, we were soon landed at the custom-house quay; and after just arriving from New Orleans, and calling to mind the magnificent quays of *Liverpool*, it certainly did appear a seriously insignificant affair, although guarded by a most splendid array of uniformed custom-house officers. Crossing this quay we passed through a short street, and came at once into the grand square, and a real beautifully square it is; on one side occupied by the palace of the Captain-General or Viceroy of Cuba, on another by shops, and on two others by fine buildings with cool massive piazzas, and built in the old Moorish style. In the centre of this square stands a fine statue on a pedestal, surrounded by iron railings, and a large space around is beautifully paved with squares of black and white marble, and here in the evening a military band plays for some time before the Captain's palace by lamplight for the amusement of the people; and very pleasant it is to hear this band, and sit (for even here chairs can be hired by those who wish them at the rate of 2½d. per evening), in the cool after the heat of the day, amidst the

delicious perfume of the plants and flowers which are grown and flourish with true semi-tropical luxuriance around the paved space occupied by the band and the pleasure-seekers. Here by day may be seen many flowers of lovely form and delicious scent little, if at all, known to the generality of Europeans, together with Aloes and Palma of several kinds, and the elegant Plantain and Banana, the fruit of which seems to melt in one's mouth rather than be vulgarly bitten and eaten; lastly, giving forth its delicious fragrance is the sweet juicy Orange common to the island.—A SURGEON.

ANNIVERSARY DINNER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—This takes place at the London Tavern, Bishopsgate Street, on the 27th inst., and Sir Wentworth Dilke, Bart., will preside. The Society is now relieving fifty-seven old gardeners, and would be able to assist as many more equally deserving if its funds permitted. We hope our readers will strengthen the subscription list to the utmost of their power. Mr. Cutler, the Secretary, will gladly hear from them at 14, Tavistock Row, Covent Garden.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EMBRACE the present favourable opportunity of the ground being moist, for thinning Beet, Carrots, Onions, Parsnips, and succession crops of Turnips; and as it is presumed that the majority of these have been sown in drills, let the hoe be run through between the drills, not merely skimming the surface of the soil, but moving it an inch or two in depth; this, while it roots out the weeds, at the same time checks rapid evaporation, and pulverises the soil. Make a small sowing of *Red Beet* and *Horn Carrot*. The former when sown early on rich soil becomes too large and coarse, and does not retain its colour in boiling, nor does it look so well in salads as that which is smaller. *Dwarf Kidney Beans*, the south border, where the early Peas have grown, may have a light dressing of manure, and should be well broken with the spade while being dug ready to receive the late crop, for which draw drills 2 feet apart, and before planting water the drills, by passing the spout of the water-pot along each. Give recently-planted *Celery* copious waterings once or twice a-week. The method frequently pursued of giving plants in the open ground a small drop of water every evening or morning cannot be too much deprecated; such sprinklings cake the ground, and lower the temperature of the soil, without affording any corresponding benefit to the plants. Pay constant attention to the watering and shading of all advancing crops recently pricked out. Get in succession sowings of Lettuces, Radishes, and saladings generally. *Scarlet Runners*, stake after drawing a little earth to them with the hoe; where it is intended to keep them dwarf, and not to stake them, let the leaders be pinched off. By constant attention to this stopping of the leaders as they advance above three or four joints in length, they will be induced to bear well; the latter mode of culture should only be resorted to where stakes cannot easily be procured. Attend to Tomatoes, sweet herbs, Cucumbers on ridges, Strawberries that have been turned out of pots, and Vegetable Marrows, and see that they have liberal supplies of water alternately with liquid manure.

FRUIT GARDEN.

Still continue active operations against aphides and other pests to fruit trees, or their ravages will spoil your best hopes of a crop. The shoots of Cherry trees infested with the black fly should be dipped in tobacco water immediately they are detected, to prevent the shoots from curling, which would stop their growth. Either pick with the hand, or apply a wash of lime or clear foot water to Gooseberries and Currants infested with the caterpillar, which increases so fast that a constant watch must be kept up for some time. Pinch back all the shoots of the latter not wanted for wood. The fruit of Gooseberries, &c., like those of more value, will be considerably improved by summer-stopping of the young wood, a fact well known to those who have paid attention to this mode of pruning. Pinch the points out of the young shoots of Fig trees when they have made five or six joints; by this means you will secure more stoecky and fruitful wood for next crop than if they were allowed to grow on. Where Strawberries are set, a few of the finest may have the fruit thinned, and unless the ground is rich it should have a good soaking with liquid manure. Those that are not for dessert will not repay the

trouble of thinning, as small and middle-sized berries are preferred by most housekeepers for preserving.

FLOWER GARDEN.

The newly-planted things will require constant watching, as under the best management failures will sometimes occur; these should instantly be made good, and the tying and staking of everything requiring support on no account delayed. Where an immediate display of flowers is not wanted, the buds may be pinched off for a week or two, to encourage the plants to cover the ground. Remove Anemones, Wallflowers, and other spring plants as they go out of bloom, to make room for autumn-flowering ones. Put in cuttings of double Wallflowers, Pansies, Pinks, &c., for next spring's blooming. A shady piece of ground on the north side of a wall or hedge should be appropriated for the above. In addition, a stock of the more showy herbaceous plants should be always kept on hand, as well as the spare bedding-out plants, so that in case of failures or alterations, a supply may always be ready for immediate planting. Creepers against walls or trellises should be constantly gone over to tie or nail them in. Standard and pillar Roses should likewise be looked over, to see that they are properly secured to their stakes. Take every means to eradicate the broad-leaved plants and coarse-growing Grasses from the lawns, which they much disfigure, and keep them closely cut with the scythe or machine. The principal operations are now completed for the summer months, and it is presumed that all beds are filled with plants for summer decoration. Next to planting succeed the tying and pegging of the plants, and a copious supply of water is of the utmost importance. We advise thorough soakings in dull days, or late in the evening; at such times exhalation is at its minimum, and the moisture is not given off as soon as supplied.

GREENHOUSE AND CONSERVATORY.

While out-of-door flowers may soon be expected in abundance, nothing should be brought into the conservatory but what is well grown and bloomed, nor should any plants be allowed to remain that are at all shabby. It is not desirable, however, to crowd the house with flowering plants; the aim should rather be to have a moderate number of handsome specimens effectively arranged, which will yield more solid interest and pleasure than a greater amount of floral display from plants of no individual merit. A thin arrangement will also be advisable, on account of the permanent occupants of the beds or borders, which at this season should be allowed plenty of space, in order to secure strong and well-ripened wood, without which they need not be expected to bloom freely. Give clear weak manure water to young-growing specimens, and repot any that are intended to have another shift this season, so as to have the pots well filled with roots before winter. Maintain a moist growing atmosphere, and syringe vigorously any plant at all infested with red spider. The main stock of Azaleas will now be getting out of bloom, and after the gorgeous display which we have seen at the International Horticultural Exhibition this season, we think they will be likely to become very general favourites. The first thing to be done with them now will be to remove their flowers and seed-pods as quickly as possible, and to place them in a house or pit where they can be properly shaded, and where a moist atmosphere can be maintained at all times. Pot such plants as require it, using plenty of sand and a little three-year-old cowdung with the peat; but as they will thrive for a long time in small pots, do not overpot them. Keep up a brisk growing temperature during the day, and syringe copiously, and shut up closely every afternoon just before the sun leaves the pit or house; air to be admitted about nine o'clock. Prune any straggling shoots, and endeavour to form nice, compact plants.

STOVE.

If among the plants there are any sickly or badly-rooted specimens, they should be frequently examined for red spider, otherwise they will become a nursery for this pest, and from them it will soon spread to adjoining plants. See that young growing stock is not allowed to suffer for want of pot room. Attend carefully to watering, giving manure water to all plants in free growth that require it. Continue to shift all such Orchids as require it. Now is a good time to pot *Peristerias*, *Phajus*, and *Cymbidiums*, that are starting into growth. The best time for shifting *Succolabiums*, *Vandas*, *Camarotia*, *Afrides*, and all similar-habited plants, is as soon as they have done blooming. In giving them new baskets, afford them plenty of room, and good open materials, as recommended in former calendars. Now that fires are discontinued here, water must

be used cautiously, but watering must be thoroughly attended to, and all plants swelling off their bulbs must be watered at least two or three times overhead, in order to make the pseudo-bulbs as large as possible. Shade with care, and give air freely, leaving a little on all night, this will in a great measure prevent the blossoms from spotting through condensation.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Just the wet, showery weather to suit all established plants, and give them a good start. Pricked out Celery, and prepared trenches, or rather beds, for strong plants, to be turned out as soon as we can find time. Just now we could employ for some time double our labour power, and then hardly have all straight. We have long held the belief that no man can be happy that is not fully employed either as respects head, or hands, or feet, or rather all united. However much there may be to be done, a man of energy will apply himself to the work and get it done, so long as he sees that his activity and hard work will be available for securing the desired object; but let the work be so extensive that the idea of accomplishing it in a definite time becomes associated with the impossible, and then, instead of a spur to activity, it insensibly acts as a damper to exertion. We say insensibly, for the workman may work faithfully without a spice even of eye-service, and yet the keen observer will see a vast difference in the results. Employers in general, and the proprietors of gardens in particular, are, as classes, not yet sufficiently impressed with the difference as respects the quality and the quantity of labour that a workman will perform when influenced merely by a sense of duty, as contrasted with a spirit of enthusiasm and a desire to please those whom he heartily respects. On this principle alone some explanation may be easily given of the seeming anomaly, irrespective of the peculiar characteristics of the different superintendents. Why, in two gardens not far from each other the workmen in one move about as if their feet spurned the ground, and in the other as if the soles of their shoes were covered with thick heavy plates of lead. We have often noticed that this latter peculiarity is most observable in large, unwieldy places, where the limited labour power strives vainly to master the work, and hence a lethargic apathy insensibly creeps over the workman. Though a man should be the master of circumstances, there can be no doubt that circumstances do greatly mould conduct and influence character. However much we rejoice, therefore, in hearing of the enlarging and the high keeping of large gardens and pleasure grounds, there can be no question that in many large places great sources of annoyance and depression to all concerned would be removed by greatly lessening their extent, so that what was professedly kept should be kept well.

On a row of Dwarf Kidney Beans in pots in the orchard-house, full of bloom and setting the pods freely, detected a trace of red spider, and had them removed at once, and turned them out of their pots into an earth pit, to be covered with old sashes in the meantime, the space in the earth pit being clear by the removal of bedding plants. But for that we would have given them a Celery trench and what protection we could afford in cold weather; but now if the weather is mild they will need little more than watering and syringing, and they will yield a plentiful supply until those sown in the open ground come in. Part of the same sowing, transferred a fortnight ago to a pit where there is a little heat, is bearing heavily. For heavy cropping and coming in at once we know nothing better than the Dwarf China, often called Robin's Egg, but it does not bear so continuously as some others. It is therefore the best, where the crop is to be taken, and then the plants to be cleared away when the first rich gatherings are over. If cut back and encouraged it will bear continuously enough; but for early crops we prefer successions, as likely to be more clean and free from insects.

The moving of these Beans is just an example of the great difference in labour power that is wanted in two places of similar extent, where little moving is needed in one place, and a great deal of moving is required in the other place, to make the very most of the space under glass, and to get as many early subsidiary crops as possible, whilst the main crop in each house receives something like justice. These are distinctive matters which some people are apt to forget when the months of June and July bring a plentiful supply of out-door produce. A gentleman told us last year that he could not make out why

his garden labourers should be so much more numerous, and yet work hard, and after all the useful parts of his garden seemed nothing superior in summer to that of his neighbour who did with one-third less labour, and yet the gardens were very much of the same extent. Nothing could have been more easily explained. His neighbour had but few bedding plants, and for these there was a little pit-house appropriated. He rarely tasted Kidney Beans until July, or new Potatoes until June, and was quite satisfied if he obtained a dish of Strawberries about the middle of the last-mentioned month. On the other hand, the gentleman who wanted his doubts solved had no place for bedding plants, but turned out many thousands, though in June no one could have told where they came from. He had been enjoying Kidney Beans since February, Potatoes since March, Strawberries since the 1st of March, and everything else in a similar proportion; and if all this was accomplished in limited space, the very moving, the taking away, and the fresh replacing, with the time required for preparing, watering, &c., would have made it quite clear to our comprehension that in his place the workmen would have a harder time of it as respects labour than those in his neighbour's employ.

The Broccoli-quarters, as well as the latest of the Cabbaging Scotch Kale being now about over, dug up the strong stems and laid them down, and to save labour will trench them into the ground along with lots of short grass from the lawn, and will follow with Peas at wide intervals, with Turnips, Cauliflowers, &c., between the spaces left. Where such crops of Broccoli stumps are very heavy, this is as quick a way of disposing of them as any, whilst they tend to keep heavy land somewhat light and drained. If a little dried before dug down we have rarely found that the stumps thus buried were made use of by the gardener's enemies. Where time would permit, we like as well to rot these stumps mixed with short grass and covered with waste earth to keep in the virtues that would otherwise pollute the air and be wasted. We have great faith in the virtues of short-grass mowings if only kept far enough from the roots of growing plants until it has become mild and sweet in its nature. As soon as the weather clears up we shall run a fork slightly along the rows of Peas and Beans to let the air in and to keep the moisture from being evaporated.

FRUIT GARDEN.

Strawberries.—The thunder showers came in good time to wash in the house sewage and thoroughly to moisten the ground, which, with the subdued sun for a few days and bright sun afterwards, will be the best conditions for insuring a good well-swelled crop. When dry enough will spread litter, &c., under the fruitstalks to keep them clean, as referred to last week.

Orchard-house.—Rain and cloudy too, yet much watering was needed for the trees in pots; we will have them mulched, as stated last week, without delay. Whether from the Kidney Beans or not, a few Peach leaves gave traces of the red spider. It was, therefore, of no use waiting for some specific, but we resorted at once to one of our old favourites for keeping the little enemy at bay. Having some softsoap we boiled about 2 lbs. of it in two gallons or six quarts of water, boiling it until it became clear—that is, about ten minutes, allowed it to settle a little, and then poured it into a thirty-gallon barrel of water, at about 100° to 110° in temperature, and set an active man to thoroughly syringe the trees, especially at the back of the leaves. Next day we did not detect one alive on the leaves affected; but we have no doubt some will be hatched from eggs in a few days, and, therefore, another application of that or something else will probably be necessary. Applied as above, though when administered the water was whitish and frothy, you would have found no traces that the trees had been syringed with anything but clear water next day. The effect of water applied as above is chiefly owing to the slight stickiness of the softsoap water. We have cleared trees of insects by applying weak glue, or rather jelly-gum water in the same way. Now, for making the red spider uncomfortable, or, as in our case, killing all where the water rested, two things must be kept in mind—first, to make the mixture weaker rather than stronger than the above; and secondly, to choose, if possible, a dull day or evening in which to apply it. Gishurst is useful for a similar purpose, but that, too, is best boiled, and then allowed to settle, and the clear matter only poured into the tub of water.

Vines, Peaches, Figs, Melons, &c., much the same as in previous weeks. In dull days kept thinning Grapes in the late

house. Very few plants are left in the vineries now, with the exception of fine-leaved Begonias, Gesneras, Gloxinias, &c., as the shade is too dense for anything else doing much good. Some Ferns will have the best places ere long as under-attractions. We care less about having plants as under-furnishing beneath the Vines until the crop begins to ripen, and then we wish all plants out, so as to have no necessity to water anything. If this wet weather continue, will take the opportunity to give all the inside of orchard-houses, and other houses where the roots are in the soil, a good watering with drainings from the farmyard, because such can be obtained in some quantity, and there will be more time for applying it when we can do little out of doors.

ORNAMENTAL DEPARTMENT.

Proceeded with planting out a good many bedding plants. The rains stopped us on Wednesday, but they did great good to all that were fresh planted, and everything that was growing, causing even the stunted grass to shoot with fresh vigour. In sandy soils the planting need not have been interrupted, but in stiff soils it is a waste of time and labour to do anything on the ground when it is wet. When parched it will scarcely ever become kindly all the season through. Whenever the soil is too damp not to part freely from the hand, the trowel, or the dibber, we consider it wisest, however great the necessity of doing the work quickly, to wait for a more suitable time. Even after the heavy rains of Monday and Tuesday, the bright sun between the showers soon made the surface of the ground nice and mellow, and planting could be proceeded with to great advantage, more especially when a board was used to save the edgings, and another smaller board for setting the feet on when it was necessary to step on the bed. Even then our planting was confined chiefly to beds which could be reached across by merely leaving one foot on the board on the bed.

Had the month of May not been past we should have deferred even such planting, as half of a bright day would make the surface soil mellow, and we have often proved how important such a state of the ground is at planting to the future welfare of the plants during the season.

In such drizzling days, too wet for planting and not wet enough to stay in-doors, though there was also plenty to do there, a good deal done in mowing, weeding, *clipping the sides of walks*, which we always prefer to do when the weather is rather damp, as the clippings are so much more easily picked up by the hand and basket—the quickest and best way in general of doing it. It no doubt may look nice and picturesque to see a tall young man draw a broom along the sides of the walk after clipping, too tall to bend to dislodge even a good-sized weed, and very systematically draw all the clippings into so many pretty little heaps, which either he himself or some one else must follow after to clear all away, and clean up the bottom of each heap. Now, whether one or two shall manage this work, we make it a point to insist, in almost all cases, that no heap shall ever be made, but all shall go in the basket and barrow at once, and thus we avoid the scraping and peddling over the bottoms of heaps. Had we our way we would never send men to this work at all, but entrust it to active boys, as in general with less pay they will do more of this kind of work, and do it well, too, when they are induced to take a pride in it; and it must be easier for a stout, short boy, even from the little space he has to go through in stooping. We have had boys that would clip in first-rate style and straight; and as for clearing up the clippings, though giving a word of encouragement, it would not have been quite safe to let the men know how much pleased we were with such work. It is such boys as these that may be depended on for becoming first-rate workmen, that can turn their hand to anything; and this is what is expected from many gardeners now.

The present is a good time for inserting in a shady place in sandy soil, with or without hand-lights, cuttings of Wallflower, single and double, Evergreen Candytufts, Alyssum saxatile, and others, Cheiranthus alpinus and Marshallii, and many other spring-blooming things. Many of the old kinds of the double Wallflower are very pretty, and chiefly because they branch so nicely. The great drawback of many of the German Wallflowers that come double from seed is, that too often the plant throws up merely one beautiful flower-stem. We like our old branching single kinds better. As soon as we can we will prick out lots of seedling Wallflowers in a border, to be ready to be transferred to where they may bloom in autumn. Pansies, or Heartsease, may now also be struck in a shady place for early autumn blooming. Firm side shoots will strike best and make the best plants; and it may be a delusion, but we

have generally imagined that, such cuttings bloom more freely than plants made by dividing the old plant into so many pieces. Pinks and Carnations will want watching for slugs, and early-struck Pinks for forcing had better be potted, and as soon as they will bear the full sun be plunged in an open space that the buds may be ripened early. Several kinds of Mulo Pinks force nicely, and now is a good time for putting cuttings in sandy soil under a hand light. Deutzias, Weigelas, Prunus, &c., may now all be struck and grown on for winter and spring decoration.

In wet hours when the men could do no good out of doors, had the flowers of *Azaleas*, partly or wholly gone, carefully removed with scissors, or by using a sharp narrow knife, and bringing the faded flower and stalk between the knife and thumb. From such work we have frequently had our thumb as well scored with the knife as to become quite tender, the slight cuts resembling the finest lacework. This must not be done in the case of plants particularly poisonous, or the effects would be serious. Now, after we have thus cleaned such plants, what are we little people to do with them, so as to bloom them moderately early, and where one house is mostly all that can be allowed for showing them off, and growing them too? We understand all about how Messrs. Turner and Veitch manage such splendid specimens as were shown at the Exhibition at Kensington, and which divided the honours with the *Roses* the *Orchids*, and the fine-foliated plants. As soon as the plants were out of bloom with them, they would be cleared of all faded flowers, be well syringed, be kept for a week or ten days in as low a temperature as the plants bloomed in, and then they would be removed to a house where a high temperature, and a close, moist atmosphere could be given to them, with every attention in watering, shading, syringing to encourage growth, with more air and light to set the buds, and then plenty of air and light to keep the plants all right until they were wanted to be gently excited again, to show their wondrous beauty. Some friends will correct this if we are wrong. Of course, in a regular *Azalea*-house, or one divided into two or three divisions, each division might be set apart to treat plants distinctively, so as to have so many successions. Gentlemen should take all these things into consideration when in their *multum-in-parvo*, and one or two places for everything—fruit, flowers, and early vegetables—the same wondrous results are not attained.

Many of us could do a good deal of what is done in regular *Azalea*-houses, by bringing the plants, when rested after blooming, into our forcing-houses, such as beneath the shade of Vines. We can recollect that once, though we detected no thrips on the *Azaleas*, it must have been there, and we not knowing it, for the presence of a few nice *Azaleas* in the vinery incurred three years less or more thrips on the Vines, and ever since then we have felt shy of introducing *Azaleas* into vineries, either to make their wood, or to force them into bloom. As a sort of compromise, we have generally placed them together when done flowering in the conservatory, and kept them as close as we could consistently with a due regard to other things when making their wood; but at that time they possessed nothing striking in themselves, and it would have been better every way to have had their place supplied with something more showy, and the *Azaleas* placed where their interests would have been the chief consideration. At this season of the year a cool glass house would answer admirably for such a purpose, as sun heat in general would give all the heat required, the regulation of air and moisture being the chief points to be attended to.

To have plants in bloom in winter and early spring, however, the great point is to have them early excited into growth, and then they will next to come early of their own accord, or with but little forcing. Whilst granting to the full the grand results accomplished by the Exhibition at Kensington, it ought not to be concealed that the proprietors of small gardens can only hope to equal such wondrous results when they grow no more than what they have ample room to do full justice to. Perhaps it would not be out of place to state here our profound conviction, with respect to which we have no fear of being contradicted, that to make the most of our ornamental plants, instead of, as now in many private gardens, being under the necessity of keeping them on the move from place to place as best we can to suit their wants, and often standing them out of doors to their injury, these plants should have abodes of their own, and then *Azalea*-houses, and *Camellia*-houses, and *Heath*-houses, and *Rhododendron*-houses for the tenderest, &c., will be as common as *Peach*-houses, and vineries, and *Pine* *Apple*-houses, &c.—R. F.

COVENT GARDEN MARKET.—JUNE 9.

We have an abundant supply of out-door produce, and a fair demand for most descriptions of it. A few Plums and Apricots are included in our foreign imports, with Strawberries, Cherries, &c. New Potatoes arrive in rather large quantities from the West of England and the Channel Islands, the best Ashleaf Kidneys realising from 18s. to 25s. per cwt.; Round from 12s. to 16s. per cwt. In old Potatoes the trade is very heavy.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

BOOKS (E. S. B. G.).—Any of the one-volume English Floras would be what you require; Eabington's "Manual of British Botany" is about the cheapest. There is no such book as would teach "enough knowledge of Latin to understand the names of plants," for the generic names are chiefly derived from the Greek.

PAULOWNIA IMPERIALIS (A. Rawson).—We are much obliged by the very fine blooms of this noble tree, produced at Bromley, in Kent. This year has been especially favourable to its blooming, or, we should be more correct in saying that last year was favourable to the formation of the blossom-buds. Very fine specimens of the blooms have been exhibited in London.

BLIGHT ON ROSE LEAF (T. W.).—It is not "a blight," for that popular name is confined to the consequences of parasitical fungi, aphides, and ungenial temperatures. On the leaf you enclose is a cluster of the eggs of some moth.

VARIOUS (H. G.).—Write to Mr. Sims, Nurseryman, Foot's Cray, Kent, for the information about Ferns. The plant you mention as shown at the International Horticultural Exhibition was not a Fern, but an aquatic plant belonging to the Natural Order Juncagaceae. Its popular names are the Lace Leaf and Water Yam; its botanical name, *Oxycandra fenestralis*. We cannot guess what kinds of plants you wish to cultivate in your plant case. Ferns and Lycopodiums would be most easily cultivated in it. Caladiums and other ornamental-leaved plants, as in Messrs. Arthur Henderson & Co.'s cases in the Horticultural Society's arcade, require heat in the cold seasons of the year.

BRUGMANSIA SUAVEOLENS BLOOM-BUDS FALLING (A Constant Reader).—The buds fall from an insufficient supply of water; the plant requires an abundance of water when the buds are swelling. The drainage must be good. We think that the buds would swell properly if you were to thin them out to one where there are three, syringe freely to keep down red spider, and give a plentiful supply of water, and manure water at every alternate watering. Before giving water let there be a necessity for it, then afford enough to reach the lowest roots.

EXPERIMENTING WITH ARTICLES ADVERTISED (P. H. G.).—Instead of incurring the expense and consumption of time you recommend, we much prefer our correspondents doing so and informing us of the results, which we readily find space for.

ROSE LEAVES CURLED (C. Bark).—We detect by means of a magnifier minute fungi on their under surfaces. Dust them with flowers of sulphur. Water the roots with weak liquid manure, and mulch over the surface.

ESCALONIA MONTEVIDENSIS (T. Pearson).—Your plant which formed its buds last autumn, and flowered in May, having white heads of bloom, is quite in character. It is one of many handsome shrubs that are seldom seen, and though it was introduced in 1827 is not in general cultivation. This may be partly owing to its not being sufficiently hardy to endure our winters in many localities, for it will only thrive in warm sheltered places, and in some it requires a wall with a south or west aspect.

ASTERS IN POTS (Constant Reader).—They succeed in a compost of turfy loam from turves a year old two-thirds, and one-third leaf mould. You may if you have it add one-fourth of cowdung a year old, or well-reduced hotbed manure, adding sufficient sand to make the soil rather sandy. It is best to use small pots at first, and then repeat as often as the roots reach the sides of the pot, giving the final shift when the flower-heads show above the leaves. Liquid manure applied twice or thrice a week after the pots become full of roots will increase the size of the plants and flowers.

DRACENA TERMINALIS CULTURE (Idem).—The leaf sent we think is that of the plant named, and if so, it does well in a compost of turfy loam and fibry sandy peat in equal parts, with one-third leaf mould, and a free admixture of silver sand, which may amount to one-sixth of the whole. Drain the pot well and pot rather low, shaking the old soil away. It will root from the stem inserted in the soil. Do not sift the soil, but chop it with a spade and make it fine. Pot firmly but not tightly. After potting keep rather close and moist in a house having a temperature of from 60° to 65° by night, and when the roots are working in the fresh soil give a light and airy situation in a warm house, in which a moist atmosphere is maintained by sprinkling of the walls, paths, and all available surfaces twice daily. Avoid syringing the foliage, also cold currents of air, which will tend to cause the leaves to become brown at the points, as in the specimen sent. Give water copiously whilst growing, but none until the soil requires it. In summer the plant will do in a moist light stove, and in winter it will sustain no injury in a temperature of from 45° to 50°, if the soil be kept rather dry. It requires a brisk heat in spring, and encouragement in the shape of moisture; it does well in a vinery in summer.

GROWING MIGNONETTE IN POTS (De Foir).—For early flowering sow the seed now in pans in a compost of equal parts loam and leaf mould, place the pans out of doors in an open situation, and keep the soil moist. When about 2 inches high prick off the young plants singly into small pots in the same compost, with the addition of one-third well-reduced hotbed manure; place them in a cold frame, and keep them close and shaded until established, then expose them to air and light, and to insure growth choose a place shaded from the sun between 9 A.M. and 4 P.M. An occasional watering is all that will be necessary up to August, and until then the flowers should be pinched off as they appear. In August shift into six-inch pots, and if the shoots are close together peg them down and out so as to keep them open. The plants will now grow rapidly and require frequent stopping and occasional waterings. Early in October shift them into eight or nine-inch pots, but still keep them out of doors and continue stopping. House the plants when it becomes unsafe to leave them out longer, and then place them as near the glass as possible, and where they can have plenty of fresh air. They do best in a cool, dry, airy greenhouse. Stop them up to December, and then allow them to go to bloom. Avoid keeping the soil wet, and give air abundantly. In midwinter you will have nice compact specimens covered with bloom, and in a convenient size of pot. If you wish for later-blooming plants, though these will continue in flower for a long time, you may sow the seed towards the end of July as before, in pans, placing them on an airy shelf in the greenhouse, where they are to remain until the plants are 2 inches high; then prick them off in eight-inch pots, four plants in each, in the compost already mentioned. The plants must be kept on the shelf until they show flower, when they may be removed to the brackets or stands where they can have an abundance of light and air. At this stage clear and weak liquid manure may be given at every alternate watering, remembering always that it and all water should be of the same temperature as the house. As the flowers begin to develop themselves liquid manure is given whenever moisture is required by the roots. Afterwards the plants are not further potted if the drainage acts well, and watering is not necessary so long as the soil retains sufficient moisture to prevent flagging. It is essential to keep the plants near the glass. We have given a mode of culture requiring pegging, stopping, and staking the shoots, and a method that needs no such attention, and we hope that one or other will meet your wishes.

SELAGINELLA CESIA CULTURE (Idem).—The plants growing in wire baskets become brown because exposed to too strong a light. At best it is not a very good basket plant, for it does not continue sufficiently long in foliage. For a few months it is rather handsome, but when the frond-like foliage loses its fresh appearance it becomes of a brown dingy hue, losing its metallic lustre, and is then the reverse of ornamental. The way we grow it is in pans 18 inches wide and 6 inches deep. After placing at the bottom a couple of inches of broken pots for drainage, the pan is filled to the rim with turfy, brown peat two-thirds, and one-third chopped sphagnum and charcoal from the size of a hazel up to that of a walnut. The plants are then taken from the store pans and laid on the surface in pieces 2 or 3 inches square and 6 inches apart, the first row 3 inches from the rim of the pan. The spaces between the tufts are filled with a compost of turfy sandy peat two-thirds, and one-third loam, broken and made fine, and sifted through an inch sieve, adding one-sixth of silver sand. This compost is put in high enough to slightly cover the tufts, and the surface being pressed gently a good watering settles all nicely around the tufts. Placed in a warm and rather dark or slightly shaded house, such as a vinery at work, if the atmosphere is kept moist and watering well attended to, this Selaginella quickly during the summer it forms a fine object in a cool shaded house, to which it should be removed from heat after a good growth has been made. We pot in spring when the young growths are an inch or so long. In winter the foliage is allowed to remain until it dies down, when it is cut off close. We keep it in winter in a house having a temperature of from 45° to 50°, giving no more water than a little now and then to prevent the soil from becoming very dry; it is best kept just moist. We repeat every other year.

PLANS OF GARDENS—BEDDING-OUT, &c. (M. N. E.).—A volume fully illustrated on these subjects is ready for the press; but it cannot be published at the price you mention.

HANUM AND OTHER FRUITS (Ellimore Lodge).—No seeds of the Hanum are now to be had. They were all sown long since. "The Pine Apple Manual" you can have from our office free by post if you enclose thirty-two postage stamps. It details the Hamiltonian and other modes of culture. Directions for cultivating the Mango and other tropical fruits were recently published in this Journal, and we have no further information to communicate.

PROFUSE SHOOTS OF JARGONELLE PEAR (J. Healdingley).—The tree from which the sparrows ate the bloom-buds in March, and which is now throwing out an immense quantity of slender shoots, should have these pinched back to four leaves, leaving the leaders, however, at their full length, and training them up or along the wall. When the shoots push again stop them at the second leaf, and continue to do so throughout the season.

LIQUID MANURE FOR ROSES IN POTS (S. W. Stears).—There is no better form of liquid manure for Roses than 1 oz. of guano dissolved in a gallon of water. It should be applied at every alternate watering from the time of the buds showing to that of their expansion.

FUNGUS IN HARDY FERNEY (J. S. S.).—The only means of thoroughly eradicating the fungus is to remove the cause—that is, to take away the roots and stumps of the trees that breed it. You may destroy it partially by throwing lime over the parts infested, and then mixing it with the soil. Lime is adverse to the development of the mycelium of most fungi, and is not injurious to the plants. Remove the fungus when first noticed, and sprinkle fresh lime over the parts infested. A little fresh soil will remove all appearance of the application.

RAISING RHODODENDRONS (A Young Gardener).—The most ready way is from seed sown in spring, or when ripe, in a cold frame, in a compost of sandy peat mould. In sowing make the surface very fine, scatter the seeds evenly, and cover them thinly with fine soil. Keep the soil just moist, and regularly so; and when up expose the young plants to light more fully by removing the sashes, but put these on during very wet weather, and keep them tilted. Be careful to keep the soil moist. The better kinds are increased by grafting on *R. ponticum*. Grafting is best done when growth commences, and before the scions push new

shoots, and the stocks should be slightly more advanced. Whip-graft immediately above the point from which the roots radiate, and cover the union with soil.

DAISIES ON A LAWN (Idem).—The only plan is to grub them up by the roots, choosing a moist time for the operation. An old table-knife is the most suitable instrument. This you will find a very troublesome operation, and one which we could never find time to fully carry out, though convinced of its efficacy. We have to content ourselves with switching over the lawns with a Daisy-knife, which takes off the heads of the Daisies, and this we do every third day. It is only in early summer that Daisies are troublesome.

CEANOTHUS PRUNING (G. E.).—Your shrub against a south wall should have the foreright shoots pinched back to 3 inches, and the shoots thinned out so that they may not overcrowd each other, leaving, however, sufficient to train in, and such shoots should not be shortened. Any short shoots that do not appear straggling should be permitted to hang at liberty. It is a good plan to cut-in the tree rather closely in spring, and to stop forerights when 3 inches long, training-in as many fresh shoots as it is possible to do without crowding; continue to do this up to August, when they may be permitted to hang loosely, and will then present a graceful appearance. Any shoots not required for filling up vacant space, and calculated to overcrowd, would be best cut clean out. We think the shoot sent belongs to *Ceanothus integrifolius*, but to be certain the flowers as well as the foliage are necessary.

ANTS IN FLOWER-POTS (J. P. F.).—The guano need only be sprinkled on the surface. Scotch snuff, also, sprinkled on the surface every day until the ants emigrate, we are told, is effectual. Bear in mind that ants are not injurious to the plants.

NAMES OF PLANTS (A Constant Subscriber).—You have been misinformed; the plant sent is not a Fern, but the common Lousewort, *Pedicularis sylvatica*. (*T. E. Drake*).—1, *Lysimachia nemorum*; 2, *Santula europæa*. (*J. Cunningham*).—1, We cannot say what your "spider-web plant" may be without seeing specimens; 2, the bottom heat is, probably, insufficient; 3, looks like a leaf of *Cobæa scandens*; 4, *Lophospermum erubescens*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 9th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BATH AND WEST OF ENGLAND SOCIETY'S POULTRY SHOW.—JUNE 4TH TO 8TH.

THIS Society dates back even so far as the year 1777. long before public exhibitions of poultry were in existence. The managers, however, anxious to do everything possible to merit public support, some years back added both poultry and Pigeons; and the result has been that from the very hour of so doing this department of their monster meetings has proved the most popular of any. The entries of this year were also in point of numbers quite beyond precedent, and the quality of the birds exhibited merits the highest approval. The general confidence in the management of this Show is best proved by the fact that scarcely any noted breeder of poultry absented himself from the competition, and that even exhibitors living so far from the place of exhibition, which was Salisbury, as Dublin and Limerick, presented themselves in strong force, and succeeded in winning prizes. The very high health and condition in which these birds were shown after their long journey from the Sister Isle reflects much credit on the management of their respective owners, more particularly as June is not by any means a favourable time of year for exhibiting adult poultry in first-rate feather. It was customary a few years ago to offer prizes for chickens at the Bath and West of England Show, and there was generally a good competition; but the egregious mis-statements in respect of age made by some few exhibitors at length became so great an evil that the Council wisely determined to abandon these classes altogether, and leave the competition for birds of any age. Singularly enough, this year only one pen of chickens was shown, and very good they were; but perhaps no class could be named in which the improbability of success could be greater for chickens than the Grey Dorking class, to which these youngsters belonged.

The arrangements for the display of the poultry deserve our highest praise, so much so that several of our most practical exhibitors expressed their opinion that they were "incapable of improvement." The tent appointed exclusively for the poultry Show was by far the best we have ever met with at any show, the length being 300 feet, and

the width 40 feet. With such an abundance of space of course all could be seen to equal advantage, there being no dark corners as at many shows; and the ventilation, although the weather proved exceedingly hot, was well provided for; nor were the birds ever left entirely to subordinates, one or other of the acting Committee being constantly in the tent. Good condition, perhaps, tells even more favourably at this time of year than any other, and consequently such birds as are somewhat late in their moult are best adapted for the Bath and West of England meetings, for it is well known that no old birds have as yet moulted out thoroughly.

The two first classes, *Black Spanish* and *Grey Dorkings*, were especially good, Lady Holmesdale repeating her usual successes in both instances. These classes, and those for the *Cochins*, seemed to be especially interesting to the Salisbury visitors, Mr. Jennison's Buffa and Mr. Stephens' Partridge-coloured Cochins interesting crowds of visitors. The *Dark Brahmas* were particularly good throughout, and that in a large entry, and the competitors had a very close run for the prizes. A very good pen of this colour, belonging to Mrs. Seamons, of Aylesbury, was "disqualified," being unfortunately entered in the "Light-coloured Brahma" class. It was a great pity, but the rule is imperative, and we cannot impress too strongly on owners the necessity of giving their undivided attention to the classes of the prize schedules whilst making their entries, as fowls wrongly entered always involve both money and trouble thrown away, without the most remote chance of prizetaking. The *Game* classes were very good; and in the Variety class a pen of Brassy-winged Game were well worthy of attention. The first-prize *Malays* were capital, and had travelled from Limerick. Unfortunately, however, the two ladies in this pen seemed as though they had been indulging in a regular Irish row during their long journey, one being scalped so sadly that we fear she will never again be able to put in an appearance as a show bird. Never has there been a Show of either *Polish* or *Hamburgh* fowls seen in this neighbourhood equal to the one at Salisbury last week. Every variety was well shown. The *Schricht Dantams* were very perfect, the Silver-laced ones especially so. *Black* and *White Bantams* were equally good.

The *Geese* and *Turkeys* were as good classes as any in the Show tent. The *Aylesbury Ducks* were A1, but the *Rouen Ducks* were many of them quite faulty in bill or feather.

Guinea Fowls are not customarily known in competition at poultry shows, but there was a very good entry, and they were evidently somewhat attractive to the public.

The Show was exceedingly well attended, and the weather on the whole favourable.

SPANISH.—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, E. Jones, Clifton, Bristol. Third, D. Parsley, Kingsdown, Bristol. Highly Commended, T. Balfield, Clifton, Bristol; A. Heath, Calne, Wilts. Commended, Rev. J. de la S. Simmonds, Chilcomb Rectory, Winchester, Hants.

DORKING (Coloured).—First and Second, Viscountess Holmesdale. Third, H. Lingwood, Barking, Needham Market, Suffolk. Highly Commended, C. Cork, New Shoreham, Sussex; C. Smith, Durrford, Salisbury; Dr. J. D. Hewson, Coton Hill, Stafford. Commended, J. C. Cooper, Cooper Hill, Limerick; Dr. J. D. Hewson.

DORKING (White).—First and Second, H. Lingwood. Commended, T. P. Edwards, Lyndhurst, Hants.

COCHIN-CHINA (Cinnamon and Buff).—First, C. Jennison, Bell Vue Zoological Gardens, Manchester. Second, J. Cattell, Bristol Road, Birmingham. Third, Miss J. Milward, Newton St. Loe, Somerset.

COCHIN-CHINA (Brown and Partridge-feathered).—First, J. Stephens, Walsall, Staffordshire. Second, Mrs. H. Pigeon, Farzedown, Hythe, near Southampton. Third, J. C. Cooper.

COCHIN-CHINA (White).—First and Third, R. Chase, Balsall Heath, Birmingham. Second, F. W. Zurlhorst, Belville, Donnybrook, Co. Dublin.

BRAMA POOTRA (Dark).—First, G. H. Roberts, Penwortham, near Preston, Lancashire. Second, J. Hinton, Hinton, near Bath, Somerset. Third, R. W. Boyle, Galtram House, Bray, Co. Wicklow, Ireland. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury, Bucks. Commended, J. C. Cooper.

BRAMA POOTRA (Light).—First and Second, J. Pares, Postford House, Guildford. Third, E. Sheerman, Chelmsford, Essex. Commended, Mrs. Easton, Ovington Down, Hampshire.

GAME (White and Piles).—First, Rev. G. S. Cruwys, Cruwys Morechard Court, Tiverton, Devon. Second, Miss S. H. Northcote, Upton Pynes, near Exeter, Devon. Third, S. Matthews, Stowmarket, Suffolk.

GAME (Blacks and Brassy-winged, except Greys).—First, C. Bulpin, Bridwater, Somerset. Second, Rev. G. S. Cruwys. Third, R. Limbrick, Kendilworth, Warwickshire.

GAME (Black-breasted and other Reds).—First, S. Matthews. Second, H. Bertram, Cowes, Isle of Wight, Hants. Third, G. Hanks, Halmesbury, Wilts. Highly Commended, W. Stratton, Ropley, Alresford, Hampshire. Commended, A. Elling, Sutton Parva, near Warmminster, Wilts; W. H. Stagg, Netheravon, Pewsey, Wilts; T. L. Mills, Orcheston St. Mary, Wilts.

GAME (Duckwings and other Greys and Blues).—First, Rev. G. S. Cruwys. Second, S. Matthews. Commended, S. Drape, Evercreech, Bath; Mrs. W. Long, Amesbury, Wilts.

HAMBURG (Golden-pencilled).—First, F. Pittis, jun., Newport, Isle of Wight. Second, H. Beldon, Goatstock, Bingley. Third, B. Mills, Mannamend, Plymouth. Commended, C. Edwards, Wrington, Somerset.

HAMBURG (Silver-pencilled).—First, H. Beldon. Second, Viscountess Holmesdale. Third, J. Holland, Chestnut Walk, Worcester. Commended, E. J. W. Stratford, Addington Place, near Maidstone, Kent.

HAMBURG (Golden-spangled).—First, I. Davies, Harborne, near Birmingham. Second, J. Walker, Haia Park, near Knaresborough, Yorkshire. Third, A. K. Wood, Burnside, Keadal, Westmoreland.

HAMBURG (Silver-spangled).—First, A. K. Wood. Second, H. Beldon. Third, J. Skinner, Maidee, Newport, Monmouth. Highly Commended, J. Walker. Commended, Mrs. Pettat, Ashe Rectory, Overton, Hampshire.

POLISH (Black, with White Crests).—First and Second, T. P. Edwards, Lyndhurst, Hants.

POLISH (Golden).—First, H. Beldon. Second and Highly Commended, Mrs. Pettat.

POLISH (Silver).—First, H. Beldon. Second, J. Hinton, Hinton, near Bath.

MALAY.—First, J. C. Cooper. Second, Rev. A. G. Brooke, Rayton XI. Towns, Salop. Third, J. Hinton. Highly Commended, Rev. G. Hustler, Stillingfleet Vicarage, York.

MINORCA.—First, H. Leworthy, Newport, Barnstaple, Devon. Second, R. C. Foster, Freshford, near Bath. Highly Commended, Miss S. H. Northcote.

CRÈVE CŒUR.—First, C. Cooper. Second, The National Poultry Company (Limited), Bromley, Kent.

ANY OTHER DISTINCT VARIETY.—First, The National Poultry Company (Limited), (Guelidres). Second, H. Beldon (Black Hamburgs). Third, P. P. Colber, Salisbury (Pheasant Malay). Highly Commended, J. C. Cooper (Houdan); C. Coles, Fareham, Hants (Andalusian); F. W. Zurlhorst (La Flèche); R. H. Nicholas, Malpas, Monmouthshire (Black Hamburg); The National Poultry Company (Limited), (La Flèche). Commended, Miss S. H. Northcote (White Spanish); E. Pigeon, Lymstone, near Exeter (La Flèche).

SINGLE COCKS.

SPANISH.—First, Viscountess Holmesdale. Second, E. Jones, Clifton Bristol. Highly Commended, H. Beldon.

DORKING.—First, S. Lang, jun., Barrow Gurney, Somerset. Second, W. K. Pancey, Chelworth, Gloucestershire. Commended, C. Hargreaves.

COCHIN-CHINA.—First, G. Manning, Springfield, Essex. Second, C. Jennison. Highly Commended, J. K. Fowler.

BRAMA POOTRA.—First, Rev. J. Ellis, Bracknell, Berkshire. Second, R. W. Boyle, Bray, Co. Wicklow. Highly Commended, J. K. Fowler; E. Pigeon. Commended, Mrs. C. Hargreaves.

GAME.—First, Rev. G. S. Cruwys. Second, H. Bertram. Highly Commended, G. S. Sainsbury, Devizes, Wilts.

HAMBURG.—First, H. Beldon. Second, E. J. W. Stratford, Addington Place, near Maidstone.

POLISH.—First, H. Beldon. Second, J. Hinton.

BANTAM.—First, R. Tate. Second, G. Manning. Commended, T. Davies, Stow Hill, Newport, Monmouth.

ANY OTHER DISTINCT VARIETY.—First, E. Pigeon (La Flèche). Second, The National Poultry Company (Limited), (Houdan).

BANTAM (Gold-laced).—Prize, Rev. G. S. Cruwys.

BANTAM (Silver-laced).—First, Rev. G. S. Cruwys. Second, Mrs. Pettat. Highly Commended, Messrs. S. & R. Ashton, Mottram, Cheshire.

BANTAM (White or Black).—First, Rev. G. S. Cruwys. Second, E. Cambridge, Bristol. Highly Commended, Rev. G. S. Cruwys; T. Davies. Commended, F. Pittis, jun.

GAME BANTAMS.—First, R. Tate. Second, Mrs. Pettat. Highly Commended, J. K. Fowler; J. Skinner, Maidee Farm, near Newport, Monmouth.

DUCKS (White Aylesbury).—First, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks. Second, J. Skinner.

DUCKS (Rouen).—First, J. E. Rawlence, Balbridge, Wilton, Salisbury. Second, J. K. Fowler. Highly Commended, J. C. Cooper; G. Hanks; C. Edwards, Wrington, Somerset.

DUCKS (Any other variety).—First, T. H. D. Bayly, Ickwell House, near Biggleswade, Bedfordshire (Brown Call). Second, T. C. Harrison, Beverley Road, Hull, Yorkshire. Commended, Mrs. M. A. Hayne, Fordington, Dorsetshire (Black East Indian).

GESE.—First, Mrs. M. Seamons. Second, J. C. Cooper. Highly Commended, J. C. Cooper; Mrs. M. Seamons; J. K. Fowler. Commended, Mrs. Easton.

TURKEYS.—First, J. C. Cooper. Second, S. Lang, jun. Highly Commended, Miss J. Milward, Newtown St. Loe, Somerset; Captain K. P. Warren, Basingstoke, Hampshire.

GUINEA FOWLS.—First, T. C. Harrison. Second, Miss S. H. Northcote. Commended, Captain H. Adney, Pemberton, near Southampton, Devon; C. Edwards.

PIGEONS.

A very excellent collection of about one hundred pens of *Pigeons* was to be seen at Salisbury. The competition in most of the classes was very severe, as it will be seen by reference to the prize list that most of our principal Pigeon amateurs had made entries. We regret to find that "trimming" Pigeons is now becoming equally general as in times gone by was customary in the poultry classes. The Judges, however, seemed determined to put a stop, if possible, to such practices, and consequently disqualified Pigeons so tampered with from taking prizes.

CARRIERS (Any colour).—First, R. Fulton, Deptford. Second, A. Court, Taunton. Commended, C. Bulpin.

TUMBLERS (Almond).—First and Second, R. Fulton.

TUMBLERS (Any other variety).—First, R. Fulton. Second, H. Yardley, Birmingham.

POWERS.—First, R. Fulton. Second, C. Bulpin.

RUNS.—First, E. Pigeon, Lymstone. Second, The National Poultry Company (Limited).

JACOBS.—First withheld. Second, C. Bulpin.

PANTALS.—First, C. Bulpin. Second, H. Yardley.

OWLS.—First, St. J. Coventry, Wimborne. Second, E. Pigeon.

TURBETTERS.—First, C. Bulpin. Second, F. Key, Beverley.

BARNS.—First and Second, H. Yardley. Commended, E. Pigeon.

TERBETS.—First, C. Bulpin. Second, H. Yardley.

DRAGONS.—First, C. Bulpin. Second, H. Yardley. Commended, E. Pigeon; H. Yardley.

ARCHANGELS.—First, C. Cowburn, Calls, Leeds, Yorkshire. Second, H. Yardley.

MAGPIES.—First, A. Court. Second, H. Yardley. Commended, C. Bulpin.

ANTWEERS.—First, H. Yardley. Second, C. Cowburn. Commended, H. Yardley; C. Cowburn.

ANY OTHER NEW OR DISTINCT VARIETY. First, F. Broemel, Lewisham. Second, H. Yardley.

The Judges for Poultry were Mr. Thomas Challoner, of Worksp; and Mr. Edward Hewitt, of Birmingham; and Mr. Tegetmeier and Mr. Harrison Weir, both of London, judged the *Pigeons*.

POULTRY TOO LATE AT THE WOODBRIDGE SHOW.

I SAW that, according to your notice of the Woodbridge Poultry Show, a number of exhibitors were shut out from competing by the late arrival of their birds. I am sorry to say that we were one of the unfortunates; and I should be glad to hear from those who were likewise sufferers, so that we may endeavour at least to obtain the expenses we have needlessly been put to from those who are in fault, and I suspect we shall all be able to lay our complaints at the same door.—MANAGER, National Poultry Company (Limited), Bromley, Kent.

REMOVING THE GAPES-CAUSING PARASITE

WHILE on the subject of poultry let me also recommend a plan I have tried for years with success when birds are affected with the gapes. It is worth all the nostrums advertised. The whole apparatus consists in a thin piece of gut, such as flies are fastened on, coarser for chickens than for Pheasants, and tolerably stiff, about from 4 to 6 inches long, and fastened at the end of the loop with a piece of sealing wax by way of handle. Put this gut down the windpipe, twist it round half-a-dozen times, and you will draw out the parasite that gives so much trouble; repeat the process two or three times and let the chicken go. From being so flexible no harm is done to the tender tube of the windpipe; wire kills as often as it cures. When a chick is first attacked is the best time for the operation. The larger the worm the more he has taken out of the chicken, and before feeding is better than after a meal. Keep

half a dozen of the loops by you, as the slime in the windpipe makes the gut limp, and you require it stiff. I now never lose a bird from this disease if taken in ordinary time.—G. W., Cardiff.

SUPERS AND SWARMING.

I HAVE some bees in one of "Neighbour's cottage hives," a last year's swarm. Last month I put on a large glass super, with a piece of comb attached to the ventilator, the bees went into the glass, and commenced working. They have enlarged the piece of comb, and partly filled it with honey, but yesterday (June 1st) they swarmed. The stock hive seems full, and the cells nearly all filled with honey.

Is it right to let the super remain on, now they have swarmed? and could the swarming be caused by too frequent looking at the super to see how they were getting on?—T. C. Wroughton.

[It may be laid down as a general rule, that when a swarm issues from a hive in which the combs are fixtures, the bees will not afterwards complete a super. There are, of course, exceptions to this rule, but as these can only occur in exceptionally good seasons, they may be left out of the question. What then, it may be asked, is to be done, and how in such a case can the completion of an unfinished super be brought about? We should advise as the course most likely to lead to the attainment of this desirable end, that the super be removed from the old stock, and placed on the swarm—say about a week after it has issued. By this time the young colony will have so far advanced in the task of furnishing its new habitation, that the queen is not likely to be driven to breed in the super, and there will be every probability that the task which the little emigrants left incomplete when they abandoned their old domicile will be satisfactorily completed in their new premises. The contingency which will remain to be guarded against, is the possibility of the adventurers storing all or nearly all their provision for the coming winter in the super, in which case they must be in some measure compensated, by liberal feeding in the autumn, for the stores of which they have been deprived.

It is, of course, inadvisable, to disturb bees by too frequent inspection, but we do not think the infraction of this rule sufficient of itself to cause them to swarm.]

RETAINING SUPERS AFTER SWARMING.

A WEEK or two back you published the different weights of my single bee-hive during the past winter, the weight on May 4th, being 29½ lbs., as shown in the Journal, No. 268, page 374. On May 8th, the weight slightly increasing, I put on a small straw hive (Payne's), 7 inches deep, 8 inches broad; this and other alterations in the hive made the total weight 38½ lbs. On the 10th, the weight had declined to 35½ lbs.; on the 15th, to 37½ lbs.; on the 21st it had risen to 41½ lbs., and the small hive was so crammed with bees, that I lifted it, and put between it and the stock hive a box 11 inches square, and 7 inches deep. This box raised the weight from 41½ lbs. to 45½ lbs. The bees at once commenced working in the box, and on May 30th the weight had increased to 52½ lbs., an increase of 7 lbs. in nine days.

All my efforts to prevent swarming, however, were useless, for on June 2nd a swarm came off weighing only 2½ lbs. Now, I am in a difficulty, for Payne's book says, "Whenever a swarm comes off leaving a small hive in an unfinished state, let the swarm be hived, and the small hive removed from the stock hive, and placed upon the newly-hived swarm, for no further profit can be expected from the stock hive beyond a second, and, perhaps, a third swarm." From what I have read in the Journal during the last few months, most of your correspondents have had swarms, and still left the supers on, and obtained large quantities of honey. I have so far left mine on, and the bees seem busy at work in them. Which is the correct plan of the two mentioned?

After the description given above, do you see anything wrong in my management that should make me unsuccessful in preventing swarming? and if not, can you account for the swarm? and am I sure to have a second?—J. R. BERTON.

[We see nothing wrong in your management, the result is just the fortune of war, or rather of bee-keeping. The first swarm will probably be followed by a second, but nothing can be predicated with certainty on this point. Read our reply to-day to Mr. Wroughton. It is, as we have there stated, only in exceptionally good seasons such as the last, that a stock which has swarmed will either fill or even complete a partially-filled

super. In answer to your concluding query about hives, we should say, No. 3 for the novice, No. 2 for the more advanced bee-keeper.]

OUR LETTER BOX.

TREATMENT OF DUCKS FOR EXHIBITION (S.).—With very few exceptions birds improve far more in condition when at liberty than when in confinement. They do not always increase in weight, but they do in health and feather. If you require positive weight you must shut them up; but the place should not be too small. An old pig-sty does very well if littered with straw where it is under cover. The food may be oats, oatmeal, and greaves. The latter make weighting fat. We are sticklers for nature, and the best exhibitors of Rouen Ducks never confine their birds. Aylesburys are more artificially got up. They require to be at liberty in the morning, as their bills become and remain pale by contact with the cold grass when covered with early dew or hoar frost.

MARKING CHICKENS (E. C. C.).—You may mark your chickens so as to know one brood from another by passing a colored waxed thread through the web of the wing. It must be securely tied and cut short; or, you may take a red-hot needle and burn holes through the web of the wing, marking the different broods or strains with one, two, or three holes. The marks are indelible, and the operation seems to cause little or no pain. You can, if you will, mark by a notch in the beak, or the eyelids; but those cocker's marks are known to every one, and detected at once by those who understand them. The marks in the web of the wing are perfectly concealed.

CRÈVE CŒUR CHICKENS (X.).—Crève Cœur, like all black chickens, are hatched with a quantity of white down about them. This should gradually disappear as feathers grow, and at two months old they should be quite black top-knotted chickens. They are pert and gay chicks, having tails developed at an early age, but do not give the idea of the size which they afterwards attain.

HEN LEAVING HER EGGS (A. J.).—Though a Brahma hen has left her nest for four or five hours on the ninth day of sitting, the eggs are not likely to prove bad in consequence.

MANAGEMENT OF THE WOODLARK (E. S. C.).—The usual plan is to feed a Woodcock on German paste, which I do not consider a wholesome food. I would recommend bread and cheese. Woodlarks clean themselves by dusting in sand. I think they will also wash in water. I expect that their feet had become encrusted with dirt owing to the birds being in a relaxed state of body, which I think cheese will correct. The bottom of the cage should be kept clean with plenty of dry sand, and, I feel sure, Woodlarks would do better with a turf to peck at. A chopped egg will be a very good addition to their bill of fare.—B. P. BRENT.

MULE'S BREEDING (Greenfinch).—It has been reported that Goldfinch Males will breed, but I never knew of a case. I have known Males pair, and even hen Mules lay small eggs, but never had any produce. There is no harm in your trying the experiment, but it is ten thousand to one against you. It is the rule for Mules not to breed; if they do, it is the exception.—B. P. BRENT.

COCKATOO PICKING ITS FEATHERS (An Old Subscriber).—We would advise you to give the cockatoo a good syringing of water two or three times a-day with a garden syringe, and keep him on scalded bread, Indian corn, and Canary seed. If the bird has plucked its feathers any length of time it is very doubtful if it can be cured of the habit of doing so. The vivary temperature of 65° to 75° is very suitable for the bird.

PURCHASED BEE-HOUSE AND HIVES (J. S. Bristol).—If the manufacturer's name be on the bee-house or the hives, it will be better to write to him for information. Should you not be able to identify the maker, we will do our best to enlighten you on being furnished with inside measurements and a detailed description of both house and boxes, stating if these latter differ from each other, and, if so, in what particulars.

KILLING MOTUS (J. B. Durham).—For entomological specimens, the best mode of killing motus is to bruise fresh laurel leaves and half fill with them a wide-mouthed jar, put over them a thin layer of cotton wool, and close the jar with a tightly-fitting bung. A moth put into the jar will be dead in a very short time. The cause of the death is the vapours of the prussic or hydrocyanic acid emitted by the leaves.

DEATH OF "KING DICK."—By a printer's mistake in my letter inserted last week respecting the death of the noted bull-dog "King Dick," I am made to say that it will be especially interesting to your readers as "King Dick" was the size of "Romantic," the bull-dog suffocated during its transit to the Sheffield Show. The fact is this, "King Dick" being the sire of "Romantic," I did think the very close blood relationship of father and son, coupled with their almost simultaneous death, was both interesting and remarkable.—EDWARD HEWITT.

GALVANISED IRON TANKS AND PIPES.—"W. T." would be glad to have information as to the suitability of galvanised iron for water tanks and pipes for storing and conveying water for clean domestic use. He fears the zinc might poison the water, rendering it unfit for drinking or cooking purposes, and is that the zinc might flake off and stop up the pipes, or quickly rust if laid under ground. Being about to lay water on to his house, a distance of about 40 yards, it seems that galvanised iron would be cheaper than any other material if it would prove sufficiently durable and clean.

POULTRY MARKET.—JUNE 11.

Our supply increases weekly, and bids fair to exceed the demand, which is dull. The doubt and uncertainty that prevail with all classes is not without effect on the poultry market.

Table with 4 columns: Item, s. d., s. d., s. d. s. d. Items include Large Fowls, Smaller do., Fowls, Chickens, Goslings, Ducks, Guinea Fowls, Partridge, Hares, Rabbits, Wild do., and Pigeons.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 72.7; and its night temperature 49.5. The greatest heat was 93°, on the 19th and 22nd, 1846; and the lowest cold 35°, on the 23rd, 1851. The greatest fall of rain was 0.72 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

MAKING A LAWN.

BEFORE sowing grass seeds to form a lawn the roots of all perennial weeds should be forked out and cleared away. The ground should also be drained effectually,

and be made level, or even in surface, whether it rise or fall. It is not necessary to have a lawn level, but whether on the level or on an incline it should be even in surface—regularly level or regularly sloping.

To secure a fine grassy surface free from irregularities it is necessary to have the ground formed to the outline desired some time prior to sowing the grass seeds. This is particularly the case when the general surface is reduced in some places, and hollows are made up in other parts. The made ground will settle considerably; it should, therefore, not only be made firm by treading or ramming, but be left for a while to settle, and after rain has fallen upon it for some time it is an easy matter to take away the heights and fill up the hollows, but very annoying after having been at great trouble to level the surface to find it, after the lawn is formed, irregular and full of holes. In levelling care should be taken to use firm soil. It is a common practice to fill up the holes with any kind of rubbish, covering it with a coat of soil for the grasses to root in; but however level it may be at first, that part formed of rubbish will invariably settle in time, leaving a hollow, and spoil the whole.

The ground being drained, free from perennial weeds, and having a firm even surface, it should be raked fine, and the seeds sown when the soil is in good order, choosing a calm day with an early prospect of rain. Gently rake the seed in with a light wooden rake, and roll firm. The best time to sow the seed is in April, for the soil is mostly then in good tilth after exposure to a winter's frost; but if the ground is very weedy it would be well to let it lie fallow part of the summer, and the weeds could then be more easily forked out. In that case the first week in September would be a more suitable period for sowing, omitting the Clover seed, which should invariably be sown in April, or at latest by the middle of August, so that the plants may become established before winter, as they are liable to suffer if this prove severe. Composed as the grasses to be recommended for lawns are of the smaller and finer kinds, it should be borne in mind that they should not be sown in autumn on cold soils or in bleak situations, spring being the only suitable seed-time for such soils and situations.

When the seed has braided, and the plant is an inch or two high, roll the ground twice a-week; this will tend to make a firm surface, cause the plant to branch, and produce a closer turf. Do not mow the grass until July. Bear

with its unawn-like appearance, knowing that every increase of head gives increase of root, and to get the roots down is a grand point in forming a lawn to look well during hot dry weather. Mow it if possible during showery weather, but if the weather be dry afterwards give it a sprinkling of rich compost; or, if the lawn be intended for playing at croquet upon, and have a damp bottom, ashes passed through a half-inch riddle, and soaked in liquid manure, should be used: sufficient to cover the ground half an inch will do much towards rendering the surface dry, and after rain there will be little of either the soil or ashes to be seen. Now is the time to roll. Roll whilst the ground is wet, for with the loose soil there is no fear of its cracking. After this roll twice a-week, and cut the grass every three weeks with the machine set an inch higher than for ordinary lawns, or if cut with the scythe cut higher, switching off the tops only. Leave off mowing, or cut for the last time in the third or fourth week in September: the grass being rather long, the taller sorts will serve as a sort of protection for those of less growth.

In March apply a dressing of rich compost, or if the ground is of a strong nature and wet, ashes mixed with half their bulk of well-rotted manure will be better, especially where a dry surface is desired. Enough of either of these to just cover the surface should be equally distributed with the back of a rake. When the grass comes through roll it well, and by the beginning of May there will be a turf free from Daisies, Dandelions, Buttercups, other perennial weeds, and coarse grasses. Thus in little more than twelve months a better turf can be obtained by sowing seed than by laying turf.

Afterwards the lawn should be treated the same as lawns generally, and if any weeds appear upon it they ought to be rooted up before they have become strong, the ground being looked over occasionally for the purpose. It is a great evil to allow perennial weeds to grow year after year without making any attempt to destroy them, except by cutting off their heads. This is a very uncertain method of destroying them, and very often more time is spent in cutting off Daisy heads during summer than would make their appearance impossible were half the time spent in taking up the roots with an old table-knife in spring. Worse even than Daisies are the coarse grasses. They grow much more rapidly than the finer sorts, and only a few days after mowing these rough erect blades give such a ragged appearance to a lawn that it seems none the better of mowing, and all the labour that has been bestowed upon it in rolling, sweeping, &c.

The beauty and perfection of a lawn consists in the evenness of the surface, whether on a level or slope; the absence of weeds, such as the Daisy, Plantain, &c., and of coarse grasses, such as *Daactylis glomerata* and many others that might be named, also moss. The advantages obtained by sowing grass seeds to form a lawn are as follow:—Greater opportunities are afforded for clearing the ground of the roots of weeds, for draining, for improving the ground, and for levelling the surface; and we can select the most permanent grasses having fine short foliage, evergreen, of one shade of colour (those of a blue or yellow

hue dotted here and there are not desirable), and deep-rooted, so that burning, and consequent browning, during hot dry weather may be avoided. These blend quickly in the turf, grow uniformly, and bear constant mowing. Further, those grasses suitable for an open, exposed, or shaded situation, and for either a heavy or light soil, can be selected, and we secure at a less cost a turf more closely approaching the standard of excellence than by any other process.

On the other hand, in laying turf there are many disadvantages. Often after levelling the ground sufficient time is not allowed for it to become consolidated before the turf is laid, and it sinks into an uneven surface; the opportunities for draining and for grubbing up the roots of perennial weeds are small; but even if the ground be drained, levelled, and allowed sufficient time to consolidate before the turves be laid, these are frequently composed of the coarser grasses, with a considerable proportion of weeds, or of grasses not suitable to the soil or situation where the turf is to be laid. Even admitting, however, that good turf can be obtained and properly laid, there is a great difference in the expense as compared with sowing. Rarely, indeed, is anything considered regarding the suitability of the turf; few ask themselves, Will it suit the soil and situation? How seldom, indeed, are the roots of perennial weeds, that may be counted by the dozen in every square foot, noticed until after the turf is laid? It takes two men twelve days to cut the turf from an acre, this at 2s. 6d. per day amounts to £3; horse, cart, and man all that time carting it a mile, 6s. per day, £3 12s.; three men to lay it, one at 3s. 6d. per day, £2 2s.; two at 2s. 6d., £3—making an outlay of £11 14s. necessary to lay an acre of ground with turf. Under any circumstances the carting of turf to lay down a lawn may be characterised as seeking an early result at any cost. A lawn may be laid down with grass seeds, and well, for £5, labour included (but not that of levelling and cleaning the ground), and the results are much better—no weeds, but a lawn of the best grasses suitable for the soil and situation. Very often more money is sunk in obtaining turf to form a lawn than would, were it desirable, be necessary to pay the labour of forming slopes, terraces, and other accompaniments, which would be new features, and give additional beauty to a place. A much better use for the turf where it can be had is to pile some of it up for compost for the growing of Pines, Vines, and ornamental plants. Whenever a lawn is taken up for the purpose of improvement it would be much better to use the turf for the purposes named, and to sow grass seeds, than to relay it. The only advantages resulting from laying turf are that it looks green at once, can be used very nearly the same as an old lawn in the first year, and is firmer and more pleasant to walk upon. A lawn obtained by sowing is of little value as a lawn during the first year, as it requires twelve months to become established, after which it is in every way superior to a lawn formed by laying turf.

There are very many lawns which, as such, are far from satisfactory, being one-third weeds and inferior grasses; others consist of but little grass, a thick covering of moss being the verdure mainly constituting the lawn; and others, again, are very uneven in surface. The best plan that could possibly be adopted with such lawns would be to take off the turf an inch thick, and use it after proper preparation for renovating fruit-tree borders, and the quarters in the kitchen garden. The soil of lawns after the turf has been taken off should be forked over, and the roots of weeds picked out. A bushel of salt, lime, and soot will make the latter into good manure in twelve months, that quantity being sprinkled on a cartload. Drain the ground as early in autumn as possible, so that the filling-in may have time to settle before seed time, also that there may be time to level the surface, form terraces, or do whatever else may be desired. The ground will be settled down by spring, and all that it will then need is to make it even by lowering the heights, and filling up the hollows, rolling and treading so as to make a firm surface, and to sow it in April with a mixture of grasses suitable for the soil and situation.

Before laying turf to form a lawn it is necessary in the first place to see that water does not remain stagnant in the subsoil, otherwise moss will be encouraged, and the grasses, being late before they begin to grow, do not root deeply, and will, consequently, be burnt up in summer. It is also desirable to lay turf from an open situation in a similar position, that from under trees in shady places, and that from either wet or dry ground in spots of a similar character. The turf should also be free from weeds, especially the coarser grasses, and more particularly those having underground creeping roots, such as couch grass, the bents, &c. I have found but few swards con-

taining White Clover (*Trifolium repens*), and the common Bird's-foot Trefoil (*Lotus corniculatus*), that were not intermingled with grasses suitable for lawns. When these were absent the herbage was found too coarse for forming a fine sward.

The best time to lay turf is early in spring before dry weather sets in, but any time during open showery weather from the middle of September to May will answer for this kind of work; but the less there is to do after the grasses commence growth up to that of its ceasing the better, so as to obviate the necessity of artificial waterings.

Where the ground is thin an addition of fresh soil is beneficial, and to loosen that on which the turf is to be laid to a good depth would very much contribute to the freshness of the lawn in summer, for the roots being deeper would not so soon be affected by dry weather. Where the soil is wet, and of a strong nature, in addition to loosening it, it would be well to lay the turf on a thin layer of fine ashes from 1 to 3 inches thick, whereas if light some fine soil is better. The turf-layer should have some loose soil or ashes by him in which to bed the turf as it is laid, and to spread thinly over it so as to fill up the crevices. The back of a rake should then be run over the turf, and when rain has fallen it should be beaten firm with a turf-beater. This may be made of a block of any hard heavy wood, as oak, elm, or ash, and may be 2½ inches thick, and from a foot to 1 foot 3 inches square, with a handle in the middle, and a cross handle in it to raise it by, as shown in *fig. 1*. This, taking a greater breadth at a time, is not so liable to beat the surface into holes, and does not cut the turf so much as a

Fig. 1.

Fig. 2.

narrower beater. It does not, however, make the surface nearly so firm as the beater represented in *fig. 2*, which is

Fig. 3.

simply the stem of a tree 9 inches in diameter cut transversely and the edges rounded a little so as not to cut the surface, the upper part being made small for the hands. This is the firmest beater of any. *Fig. 3* is a smaller form of beater, with the handle fixed obliquely, and, in beating, is used in the same way as the back of a spade.

After the ground has been rendered firm by beating, a good watering will be of service if the weather be at all dry, going over the ground with a heavy roller the day afterwards. The best rollers are those of large diameter and narrow, as they can be

turned easily, and do not cut the grass or destroy the turf in turning. The best of all the rollers that I have tried are those with rounded edges and having a division in the centre.

If the grass is thin a few pounds of seeds should be sown previous to rolling, selecting those suitable for the soil and situation, and one-sixth of the quantities required for sowing an acre. Of the Clovers, however, full quantities should be sown if the situation is open, only one-half if the plot is to be used as a croquet ground or for a promenade, and they should be left out altogether if the situation is shaded. The rolling will fix the seeds in the soil, and they will grow without any further trouble should the weather prove showery.

Perhaps the best of implements for paring the sod is that known as a turf-plough, common in districts where peat is

Turfing-spade.

used for fuel; failing this, one can easily be made out of an old hay knife, the handle or socket being bent upwards, and furnished with a strong shaft and cross-handle to push the implement. Before using it the turf is cut with an edging-knife into strips an inch less in breadth than the width of the

Edging-knife.

turf-parer, and crosswise at every 4 feet; and in raising the turf one man pushes the parer, and another rolls up the turf as cut, grass side inwards, and lays it on the cleared ground; but a better plan is to have a barrow at hand, in which the rolls of turf can be placed, and taken out of the way at once, instead of their being laid on one side and lifted again. These rolls should be laid on their ends in a shady place, and not more than two or three tiers high, for if laid too high one above the other they are liable to heat and become destroyed in a short time. Turf cut and rolled up in this manner will keep fresh for three weeks or a month in September, October, March, or April; in the winter months it will keep for a month or six weeks, and all the time it remains frozen, whilst from April to September from ten days to a fortnight is about as long as I have found the sods retain moisture sufficient to keep the grass fresh. The sooner the turf is laid after being cut the better. This, however, cannot always be done, therefore the above data may be of service.

In forming a lawn for a croquet ground or bowling-green, the chief points to be attained are to secure a level surface, a firm, close, fine turf, and as dry as possible consistent with a verdant lawn. The size of a croquet ground depends on that of the place, for it may be either ornamental or out of character, just as it is large or small in proportion to the size of the grounds. I have seen such lawns as small as 12 yards square, which is much too small for properly playing the game, double that space being required. A lawn 30 yards by 20, and either rectangular or oval, forms an excellent croquet ground, and so does a square of 25 yards on the side, or a circle with a corresponding diameter, but the ground may be of any size or shape, and simply a lawn, or accompanied with decorations of various kinds. Some croquet grounds are sunk and have a terrace round them with corresponding slopes, others are surrounded by banks or borders of shrubs, others by borders and beds of flowering plants, they being the ugliest of all.

There is no finer object in ornamental gardening than a fine lawn, whether it is in one broad unbroken expanse, or forming the groundwork for the artistic arrangement of beds, or the display of plants, shrubs, and trees.—G. ABBEY.

LEEDS HORTICULTURAL SHOW.—This took place on the 6th and 7th inst. The prizes were on the most liberal scale, and the Exhibition, especially of fruit, very superior. A letter informs

us, that owing to the unfavourable weather the visitors were comparatively few, and that, consequently, "the expenditure was £400 over the receipts." We hope that so wealthy a locality as Leeds and its vicinity will not allow this loss to fall upon the Committee.

PRINCESS MARY'S WEDDING BOUQUET.

EVER since the marriage of the Princess Royal, Mr. Veitch, of the Royal Exotic Nursery, Chelsea, has enjoyed the privilege of presenting the members of the Royal Family with their wedding bouquets. That honour and privilege have on the recent marriage of the Princess Mary of Cambridge been again accorded to that establishment, and Messrs. Veitch & Sons by special permission presented the Princess with a splendid bouquet, which consisted of Orange blossoms, Phalanopsis, Odontoglossum pulchellum, Calanthe, Burlingtonias, Stephanotis, white Roses, &c., the garniture being of Honiton lace. We believe Her Royal Highness was graciously pleased to accept it personally from the hands of Mr. Harry J. Veitch.

MILDEW ON APPLE TREES IN TASMANIA.

I ENCLOSE a twig and leaves of a diseased Apple tree for your inspection, with the view of eliciting from you an opinion as to what the disease really is, and the remedies you would recommend for its extirpation. This disease has become general in Tasmania, and many trees in large orchards are entirely ruined by it. The Stone and New York Pippins are very susceptible of its attacks; in fact, more so than any other varieties that I could name. Can you explain the reason why such is the case?

I have seen a plantation of Stone Pippin trees in an orchard near Hobart Town, quite destroyed by this plague. The appearance of these trees (in the summer of 1854), was as if they had been scorched by fire, and by gently rubbing the foliage between the hands it was reduced to dry dust. A microscopic examination of several diseased leaves, leads me to believe that this disease is nothing less than a form of Erysiphe communis, or mildew. However, this needs confirming by some of the savans in horticulture at home, or if you will have it so, of the mother country.—JOHN OSBORNE, JUN., *The Nurseries, Pine Apple Place, Hobart Town.*

[The leaves sent are very intensely mildewed, and we think the fungus is not an Erysiphe (certainly not Erysiphe communis), but Sporotrichum macrosporum. Sulphur does not seem to check it much, but a washing of the trees when at rest with a brine of 8 ozs. of salt to the gallon of water acts as a preventive; and if the mildew appears when the trees are in leaf, a good syringing with lime water made by pouring thirty gallons of water on 14 lbs. of fresh lime, stirring the mixture well, and allowing it to stand forty-eight hours, and then using the clear water, checks the spreading of the fungus. Something, however, should be done to prevent the mildew occurring; and for this purpose we recommend the surface of the soil over the roots to be mulched, and other means adopted to keep the roots near the surface. We think the mildew would not be so intense if a more vigorous root-action were maintained.]

PRESERVING SOWN SEEDS.

THE destruction of seeds by birds and mice being a subject of very considerable importance to gardeners, I submit the following for insertion in your columns. I noticed in a late Number of the Journal, among the "Doings of the Last Week," by "R. F.," that he complains of birds eating his Radish seeds; and I have little doubt that, at times, also, he finds they eat other seeds belonging to the natural orders Brassicaceæ and Fabaceæ. He also complains that nets are not sufficient protection. Therefore for his information, and that of others who suffer from these garden pests, as I used to do, I can recommend them to try the following plan, having tested it in various ways, and constantly practised it here for the last five years; and I now never have to use a net or any other protection, when formerly I could scarcely keep even a crop of Turnips safe from birds or Peas from mice.

My practice is in spring to purchase 2 lbs. of dry red lead, which lasts me for the season for all the seeds of a large kitchen garden, and costs 8d. Before sowing, I put the seeds into a basin, and sprinkle just a few drops of water—sufficient only

when well stirred up just to damp every seed. I then, on the flat end of a small label, add to an ounce of seed about half a small teaspoonful of the red lead, which when stirred up is found to give a good coating to every seed. I then, to cause the seed to leave the hand readily, stir through it a little dry sand or earth.

I find that by adopting this means birds never give me the least trouble, neither does the lead in the least degree impair the vitality of the seed. Peas also, I believe, if properly coated will be quite safe from mice, and, I would be inclined to think, from pheasants also. Should any one be induced to give the plan a trial perhaps he will report the result in this Journal.—*ALLAN GOODMAN, the Palace Gardens, Londonderry.*

LIST OF THE PAPERS AND SUBJECTS PRESENTED TO THE BOTANICAL CONGRESS.

(Continued from page 438.)

PROFESSOR E. MORREN, Liège :

1. On the influence of coal gas on vegetation.
2. On double flowers.

DR. FERD. MUELLER, Melbourne: On the cultivation of the Cinchona in the South of Europe.

The culture of the Cinchona in the Madras Presidency, according to authentic calculations, holds out most startling prospects of remunerative yield; and there can be no doubt that Peruvian Bark-tree plantations will be among the most lucrative in any locality where these plants will prosper. The facts thus beyond dispute ascertained in India lead to the reflection how far Cinchona culture can be extended over the globe. From trials instituted in the Botanic Garden of Melbourne it is apparent that for the cultivation of Cinchonas no absolute necessity exists for the rarity of air of those mountain regions of the Andes, the proper home of these trees. On the contrary, it would seem that merely a mild warm temperate atmosphere, combined with humidity and shelter, is required for Peruvian Bark plants; and as in the Cinchona plantations of India extra-tropical Australian and Mediterranean plants do prosper, the question arises whether their cultivation could not be pursued to advantage in moist valleys on the Mediterranean shores, and in any other isothermal zone. In Victoria arrangements are made to try the growth of these plants in the extensive Eucalyptus gullies which abound. For these experiments more extended facilities now exist since Cinchonas have commenced to ripen their seeds in India, and since the generosity of the Indian authorities has rendered some already available here.

Under any circumstances it appears desirable that in South Europe and elsewhere experiments should teach us how far these plants adapt themselves to the somewhat altered influences which they will experience.

PROFESSOR PARLATORE, Florence: On the species of Cotton.

PROFESSOR PYNAEKT, Ghent: On the methods of obtaining new varieties of fruit trees, and on raising improved varieties from seed.

PROFESSOR REICHENBACH, Hamburg: On some points connected with Orchideæ.

MR. RIVERS, Sawbridgeworth:

1. On the culture of fruit in nicated glass structures.

A brief history of orchard-houses, and the latest improvements in their construction and ventilation. A short account of the kinds of trees to plant in them. A new method of forming the borders for the reception of the trees. An improved mode of cultivating Apricots under glass, so that crops are insured. The culture of Cherries in orchard-houses, and the stocks proper for them, is entered into. The cultivation of the finer kinds of American Apples in orchard-houses is recommended, and that of Pears and Plums slightly touched on.

2. On dessert Orange culture in England.

This paper describes the perfect success of the culture of Oranges for some seasons past. The method by which they are made to ripen their fruit perfectly in about eight months, so that ripe Oranges may be placed on the table immediately after the late kinds of Peaches or Nectarines. The most eligible kinds of Oranges for English culture are named. The outlines of their management, and the proper temperature of the dessert Orange-house are given.

3. On raising Peaches, Nectarines, and other fruits from seeds.

PROFESSOR SCHULTZ SCHULTZENSTEIN, Berlin: On the presence and source of nitrogen in turf or peat, with reference to its use as a manure for plants.

The author in this paper controverts the opinion of most chemists—that plants derive the carbon and nitrogen which they contain from the air and not from the soil. "Practical experience contradicts this theory." The author proposes to use turf as a manure, from the quantity of nitrogen that it contains, and which obviates the necessity of using animal manure. The nitrogen of the turf originates from the remains

of animal life in it, such as infusoria, worms, mollusca, &c. Turf does not decompose so quickly as animal manure, but it is on that account the more efficacious. The author has not found any advantage in adding bone dust (phosphate of lime) to the turf, which, indeed, contains a sufficient quantity of that substance.

MR. W. G. SMITH, London: The Corona of Narcissus.

Basing his argument upon analogous structures in other plants, Mr. Smith considers the corona of Narcissus to be made up of a series of confluent petal-stipules, leaving the normal six stamens and six petals as in the rest of the Amaryllidaceæ.

SIGNOR TRIANA, Kew: On the manuscripts and beautiful drawings made under the direction of Mutis in his botanical expedition to New Grenada, and which are preserved at Madrid.

Signor Triana desires to draw attention to the existence at Madrid of a most interesting collection of manuscripts and drawings made by Mutis and preserved at Madrid, where they have practically been forgotten for many years. Among them are figures of species of Cinchona, &c. It is greatly to be hoped that the Spanish authorities will at least carefully preserve these valuable documents, and render them easily accessible to botanists.

MR. ROBERT WARNER, Broomfield, Chelmsford: On cool vinery Orchids.

M. HERMANN WENDELAND, Herrenhausen: Note on the culture of Palms.

The author, in this paper, insists upon the paramount necessity of supplying Palms with an abundant supply of water.

MR. TUFFEN WEST, London: On the structure of the testa of the seed of Solanacea.

Details a series of microscopical observations on the outer covering of seeds. Mr. West describes the peculiarity in the cell structure of the testa in different genera, and shows that such structures afford constant characters. A peculiar structure is present in the testa of many Solanaceæ. It is a form of barred tissue, constituting a support to the lateral walls of the cells; in which portion of the cells the primitive membrane is found in mature seeds to have disappeared more or less completely. The inner walls are greatly thickened by horny and even crustaceous deposit; in addition to their (usually) very sinuous outline, the edges of the inner walls are also elongated by undulation; from these edges processes arise which form a fringe having the appearance of hairs. By examination of numerous examples this structure proves to be a form of barred tissue, which, by various intermediate conditions, passes in *S. iodamm* and *S. jasminoides* into a reticulate tissue. The author is very desirous to procure seeds for microscopic examination, the results hitherto obtained promising to possess interest and value in proportion to the extent to which they are systematically carried out.

DR. WIGHT, Reading: On the phenomena of vegetation in the Indian spring.

Dr. Wight offered a suggestion towards explaining the difficulty in accounting for the sprouting of trees during the hottest and driest months of the year, at a time when the heat and drought would seem enough to wither up vegetation. It is a phenomenon often observed, and always with wonder, but one which may, he thinks, be accounted for on the same principles as the swelling of the buds and renewal of spring vegetation in higher latitudes—namely, by change of temperature stimulating the flow of sap rendered sluggish by previous cold. In the high latitudes, where the cold is often intense, the susceptibility of plants to heat becomes so acute that the rise of only a few degrees of temperature above the freezing point sets the circulation in motion, especially when the soil in which the roots are distributed is still unfrozen, and permits absorption by the rootlets. Here the action of the roots and stem are simultaneous through the rise of temperature of the air equalising that of the soil in which the roots are distributed, permitting freer circulation to take place, and with it a renewal of the operations of vitality and growth.

Applying this principle to tropical vegetation, we must bear in mind that, owing to the high range of temperature in which the plants habitually grow, their susceptibility to variations of temperature is at the minimum, so that it is not until a considerable rise has taken place that the effect becomes obvious. Again, as in the other case, synchronous action between the stem and roots is necessary. "The hottest and driest month of the year" is preceded by the wettest and coldest, during which the soil is first saturated with moisture and then cooled by subsequent evaporation to a temperature considerably below that of the air. Then it is that vegetation in arboreous deep-rooting trees flags until renewed by the heat of the advancing season restoring the equilibrium between the roots and branches. Then indeed tropical vegetation in all its glorious perfection is seen. These are the circumstances in which a Bamboo shoot can almost be seen to grow, and its progress marked from hour to hour at the rate of nearly a foot a-day, or even more than that.

This principle of synchronism between the above and below-ground portions of arboreous plants, carefully applied, will, the writer apprehends, be found applicable to the explanation of several apparent anomalies presented by the renewal of vegetation after the annual

rest, and in the hands of ingenious horticulturists may, he thinks, be turned to good practical account.

Mr. WILLIAMS, Huntröyde Park, Burnley: On sports produced from Mrs. Pollock and other Pelargoniums.

The author is of opinion that the varieties of variegated plants cannot be perpetuated from seed, but only by propagation of sports.

ROYAL HORTICULTURAL SOCIETY.

JUNE 14TH.

COMPETITION FOR PRIZES OFFERED BY FELLOWS.—The subjects brought forward in competition for these prizes constituted a special show, which, though neither very brilliant nor extensive, was, nevertheless, of considerable interest. A greater proportion of flowering plants and cut blooms would have rendered it much more attractive.

THE PRESIDENT'S PRIZES.—The first prize, offered by the Duke of Buccleuch, for the best nine plants sent out in 1865, was taken by Messrs. Veitch, with *Adiantum colpodese*, somewhat resembling *A. capillans-venetis*, but with the young fronds tinged with copper colour; *Verschaffeltia splendida*, a beautiful Palm; *Alternanthera spatulata*, with red foliage of various shades, and which if sufficiently hardy may be useful for edgings, but it is a native of Brazil; *Peperomia maculosa*, with thick, silvery-veined, concave leaves; *Dieffenbachia Weirii*, with deep green leaves, conspicuously blotched with pea green; *Draecena nigrescens*, with very dark foliage; *Bertolonia pubescens*, with olive green leaves broadly edged with bright green; a Juniper from the north of China; and *Gymnogramma flexuosa*, an elegant kind, with a shining black rachis. The second prize, which in this as in the other classes was added by the Council of the Society, went to Mr. Bull, who exhibited *Verschaffeltia splendida*, *Draecena nigrescens*, the white-variegated variety of *Selaginella Martensii*; *Terminalia elegans*, with leaves resembling those of *Pavetta borbonica*, but trifoliate; *Coprosma Baeriana variegata*, with obovate leaves variegated with cream-colour; *Cycas plumosa*, with rush-like foliage; *Saurauja sarapigensis*, with handsome leaves having reddish brown midribs; *Aucuba japonica femina elegans*, with the foliage marked with creamy blotches, sometimes occupying three-fourths of the entire leaf; and *Asplenium myriophyllum*, a slender species, with finely-divided fronds.

The next class was for the best nine plants sent out in 1864 and 1865. Here Mr. Williams was first with *Anthurium Scherzerianum* and *cordifolium* or *magnificum*; variegated *Panajus* Grass presenting much the appearance of Gardener's Garters; *Calamus Imperatrice Marie*, a graceful Palm, with ivory spines on the under side of the petiole; variegated New Zealand Flax; a good plant of *Agave Schidigera*; *Phalenopsis Luddeemanniana*, with nine blooms; *Dieffenbachia Baraquimiana*, with white leaf-ticks, and *Draecena Cooperi*. Messrs. Veitch were second with *Dieffenbachia Weirii*; *Draecena nigrescens* and *Cooperi*; *Anthurium cordifolium* and *Scherzerianum*; *Cyrtopodium Pearcei*, with two blooms, having short tails; *Gymnogramma Pearcei*, a graceful greenhouse species; *Pandanus ornatus*, with glossy green leaves varying in intensity of colour according to their age; and *Prumnopitys elegans*, a Conifer having glossy Yew-like foliage. From Mr. Bull, to whom an extra prize was awarded, came *Zamia cycadeifolia*, *Anthurium cordifolium*, *Pandanus ornatus*, *Draecena Cooperi*, *Maranta Van den Hecke*, handsomely banded with white; *Podocarpus macrophyllus variegatus*, having dark green leaves variegated with white, intermixed with others wholly white; a large green-leaved female *Aucuba*; *Zalacca Wagneri* and *Salpicchiena volubilis*, with large, deep green fronds.

The first prize for single trusses of thirty-six Roses, including varieties sent out in 1864 and 1865, went to Mr. Turner; the second to Messrs. Paul & Son; and in the class for the best collection of new Roses sent out in the years just mentioned, the positions of the same exhibitors were reversed. Roses were generally not in good condition, but we remarked good examples of *Olivier Delhomme*, *Leopold Haussburg*, *Charles Lefebvre*, *Victor Verdier*, *Maurice Bernardin*, *Prince Camille de Rohan*, *Gloire de Dijon*, *Exposition de Brie*, a very promising sort; *Joseph Fiala*, *Madame A. Halphen*, *Dr. Andry*, *James Veitch*, peculiar in colour, and *Rev. H. Dombraim*. A fine boxful of *Madame Victor Verdier* was shown by Mr. Turner; and another of *Princess Mary* of Cambridge, by Messrs. Paul & Son. This variety, about which some difference of opinion has existed, improves upon acquaintance, and when half blown is a pretty, pale rose-colored flower.

MR. W. WILSON SAUNDERS'S PRIZE FOR EXOTIC ECONOMIC PLANTS.—The only competitor was Mr. Bull, who was adjudged a first prize for healthy plants of the following:—Alligator Pear (*Persea gratissima*), Allspice (*Eugenia pimenta*), Annoto Dye Plant (*Bixa orellana*), Arrow-root (*Maranta arundinacea*), Balsam of Peru (*Myroxylon Pereira*), Bamboo Cane (*Bambusa arundinacea*), Bark of Commerce (*Cinchona nobilis*), Betle Pepper (*Piper betle*), Black Pepper (*Piper nigrum*), Black Tea (*Thea Bohea*), Cabbage Palm (*Euterpe edulis*), Cardamom (*Amomum cardamomum*), Chinese Plantain Tree (*Musa Cavendishii*), Cocoa (*Theobroma cacao*), Cinnamon Tree (*Cinnamomum verum*), Clove Tree (*Caryophyllus aromaticus*), Coffee (*Coffea arabica*), Contrayerva Root (*Durstenia contrayerva*), Cotton Tree (*Gossypium herbaceum*), Croton Oil Plant (*Croton cascarrilla*), Cubeba Pepper (*Piper cubeba vera*), Date (*Phoenix dactylifera*), Gamboge (*Xanthochymus*

pictorius), Ginger (*Zingiber officinale*), Graauidilla (*Passiflora laurifolia*), Green Tea (*Thea viridis*), Grey Bark (*Cinchona cordifolia*), Gutta Percha Tree (*Isonandra gutta*), India-rubber (*Ficus elastica*), Ipecaeanha (*Cephaelis ipecaeanha*), Jalap (*Ipomoea jalapa*), Lutanier Palm (*Lutania borbonica*), Lemon Grass (*Cymbopogon schamantens*), Loquat (*Eriobotrya japonica*), Mango (*Mangifera indica*), Mangosteen (*Garcinia mangostana*), Manila Hemp (*Musa textilis*), Mastie Tree (*Schinus molle*), Matico (*Artanthe elongata*), Nutmeg (*Myristica moschata*), Ordeal Bean (*Physostigma venenosum*), Palissandra Wood (*Maclurium firmum*), Papaw Tree (*Carica papaya*), Paraguay Tea (*Ilex paraguayensis*), Patchouli Scent Plant (*Pogostemon patchouli*), Red Bark (*Cinchona succirubra*), Rice (*Oryza sativa*), Sarsaparilla (*Smilax sarsaparilla*), Soap Berry Tree (*Sapindus saponaria*), Sugar Cane (*Saccharum officinarum*), Sugar Palm (*Arenga saccharifera*), Sweet Potato (*Batatas edulis*), Sweet Sop (*Anoua squamosa*), Tallow Tree (*Stillingia sebifera*), Travellers' Tree (*Ravenala madagascariensis*), Vanilla (*Vanilla aromatica*), Violet Sugar Cane (*Saccharum violaceum*). Besides the collection of the above plants shown by Mr. Bull, a number came from the Society's garden. Among these were Sugar Cane, Tobacco, Peppers, Ginger, Peruvian Bark, Gamboge, Lemon Grass, the Candle Tree, the Chocolate Tree, Paraguay Tea, and the Alligator Pear.

LADY DOROTHY NEVILL'S PRIZE FOR EXOTIC FERNS.—The best ten came from Mr. Williams, of Holloway, and consisted of handsome specimens of *Cyathea dealbata*, *Dicksonia antarctica* and *squarrosa*, and excellent examples of *Cibotium princeps*, *Lomaria gibba*, *Todea africana*, *Woodwardia radicans*, *Gleichenia semi-vestita*, and the Bird's-nest Fern (*Neottia vulgaris*). The last was in splendid condition, having fronds from 3 to 4 feet in length, and of which the bright shining green formed a striking contrast with the purplish brown midribs. In Mr. Bull's ten, which were second, were fine trees of *Dicksonia antarctica*, and *Alsophila excelsa*, *Cyathea*, *Alsophila australis*, *Marattia elegans*, *Dicksonia cinnamomen*, and *Gleichenia semi-vestita* and *microphylla*. Mr. C. Walton, Manor House, East Acton, had an extra prize for smaller plants, among which were *Pteris tricolor*, with a young frond finely coloured, several *Adiantum*, *Pteris serrulata*, the long, narrow, grass-like divisions of the fronds of which are so useful for floral decorations; *Pteris tremula*, *Woodwardia radicans*, and the glossy green *Cyrtotium falcatum*.

MAJOR R. TREVOR CLARKE'S PRIZE FOR BROMELIADS.—This was awarded to Mr. Williams, of Holloway, who was the only exhibitor. His collection contained the variegated *Ananassa*; *Guzmania grandis*, with pale green leaves mottled with dark green; *G. tricolor*; several *Nidularium*, two of the prettiest being *N. Innocentii*, and *Meyendorffii*, both with red bracts, and the former having the reverse of the leaves of a metallic dark purple; two species of *Hechtia*, with the spiny leaves gracefully curving downwards; *Pnja recurvata*, a handsome plant; and *Dyckia remotiflora*.

Prizes for Tropical and Sub-Tropical Fruits, Strawberries in Pots and Filing Ferns, were offered respectively by Mr. W. Wilson Saunders, Dr. Hogg, Mr. G. F. Wilson, and Mr. Alexander Scrutton, but no competitors came forward.

LADIES' PRIZES FOR IN-DOOR PLANTS.—These were offered by the proprietors of the *Gardener's Chronicle*, and, as was the case two years ago, the first was awarded to Mrs. Dombraim, Deal, for a good healthy plant of *Adiantum cuneatum*, which had been grown upwards of two years in a sitting-room where gas is burnt. The second prize went to Mrs. Marshall, The Firs, Enfield, for *Davallia canariensis* in excellent health, though it had been kept five years in a sitting-room. Miss Fisher, City Road, took the third for another Hare's-foot Fern, which, it was stated, had been kept in a room nine years, and it, too, was well grown and in excellent condition. From Viscountess Doneraile came *Zelmea fulgens*, *Aspidistra lurida variegata*, and *Draecena Cooperi*, each of which had been kept in a drawing-room in London since the beginning of April; from Mrs. Hooke, Enlham, *Cyrtopodium barbatum majus* with six good blooms, and kept seven weeks in a drawing-room; and from Miss Williams, Highgate, *Draecena grandis* and *Rhynchospermum jasmoides*, each of which had been six weeks in a room; also, *Rhapis humilis*, ten weeks. Mrs. Wyatt, Upper Tooting, exhibited *Lonicera arce-rotundata*, trained on a flat trellis to form a window-screen; and the same Honey-suckle, balloon-trained, and intermixed with *Manranda Barclayana*, came from Lady Adaliza Norman, Campden Hill. Mrs. Hill, Highgate, contributed two plants of *Bigonia insignis*, which had been growing for fifteen months in a window facing the north, and a plant of *Richardia aethiopica*, with excellent foliage, which had been six months in a similar position. Miss Baring, Surbiton, had a silvery-leaved *Begonia*; and Miss Bannerman, Upper Tooting, a window-screen of German Ivy, and ornamented with *Roses*, *Rhododendrons*, and other cut flowers, and Ferns at the base.

MISCELLANEOUS.—Extra prizes were awarded to Mr. Burley, Albert Nursery, Baywater, for Palms, *Draecenas*, and *Alpina nutans*; and to Messrs. E. G. Henderson for tricolor and variegated-leaved Pelargoniums, and for novelties, which, along with other subjects, are separately noticed in our Floral Committee report. From Messrs. Veitch came *Lilium auratum*, producing semi-double flowers, and from Mr. Bull *Maranta splendida*, *Lindenii*, rose-picta, and *Bertolonia margaritacea*, all remarkable for the great beauty of their variously-marked leaves. Mr. Williams, Holloway, contributed variegated *Orchids* in beautiful condition, especially *Anæctochilus Lowii* and *intermedia*; Mr.

Salter, double Pyrethrums, exhibiting a great variety of colour, and approaching to Chrysanthemums in size and regularity of flower; also German Irises and very fine herbaceous Peonies. Mr. Salter received extra prizes for these and for the Pyrethrums, and a similar award was made to Mr. Turner for a dwarf double early-flowering Pink, called Rubens, which was stated to be excellent for forcing. Mr. Turner and the Rev. G. Cheere, Papworth Hall, also exhibited good Pinks of the florists' varieties. Large fruit of the Castle Kennedy Fig were shown by Mr. Fowler; and other subjects exhibited consisted of several handsome plant-cases from Messrs. Barr & Sugden, for which an extra prize was awarded; drawing-room ornaments in glass and china from Messrs. Mellishup & Harris, Westbourne Grove; and wedding bouquets from Messrs. Lucking Brothers.

SUB-FLORAL COMMITTEE.—There were not many subjects for examination; probably, the next Tuesday meeting being so near at hand, many plants were reserved for that occasion. Messrs. Jackman, Woking, exhibited seedling Clematises in five varieties—viz., Jackmannii, which had been awarded a first-class certificate in 1864; Magnifica, a dull red and purple flower; Volutina purpurea, to which a first-class certificate was awarded, a bright plum or reddish purple colour, and distinct; Alexandra, a lighter purple; and rubella. These flowers were not equal to the first seedlings sent out by this firm. From Mr. W. Barnes, Cumberwell, came Azalea Her Majesty, a sport from Criterion, distinct in colour, a pale silvery grey with occasional pink stripes, the back petals distinctly spotted; flower of good substance—a first-class certificate was awarded it. Messrs. Perkins, Coventry, sent Verbena Shakespeare, bright orange scarlet, very fine truss, with very large pips, having a yellow centre. We have seen no flowers of Verbena equal to this in size. It will be useful as a show flower, but we should question its properties; as a bedder, it will be a universal favourite and be much admired. It received a first-class certificate. From Mr. W. Thompson, Ipswich, came cut spikes of Pentstemon glaber, a bluish and pale lavender colour; also Eriogonum umbellatum, producing clusters or umbels of small pale yellow flowers. Messrs. Henderson, Wellington Road Nurseries, sent a collection of novelties, which were entered in the Miscellaneous class, but which they requested should be inspected by the Committee. In this collection were several tricolor-leaved Pelargoniums, among them the old favourite Lucy Grieve and Sophia Dumaresque, the latter very brilliant in its colours; also, six other unnamed seedlings. One with very circular foliage, with an intense dark zone, relieved by brilliant colours, promises to be of considerable merit; but the number of seedlings of this section of the Zonales makes it difficult to select specimens entirely distinct and novel, there is a great similarity, and Mrs. Pollock has not yet been eclipsed. A large pan of the variegated Poa trivialis, which was very beautiful, among the best of the variegated Grasses, was exhibited by the same firm—it had received a first-class certificate at a previous meeting; also two forms of variegated Stella Pelargonium, one a sport with yellow variegation, and orange scarlet flowers; the other white-variegated, with deep red flowers. There seems to be no limit to variegated Stellas; we have heard of five or six, and have seen better than those exhibited. Messrs. E. G. Henderson likewise contributed Santolina incana, a plant used for edgings, and having a strong aromatic scent; a variegated Zonale Pelargonium, with broad white edges to the leaves; a double Zonale Pelargonium, called Gloire de Nancy, with deep carmine flowers, the best double Zonale yet exhibited, but by no means an improvement on the glorious trusses of the single scarlets; flowers of four seedling varieties of Clanthus Dampieri, one a bright red with dark red markings in the place of the usual black spots at the centre of the flower—this appeared a very distinct variety; and some plants of the new variegated Maize or Indian Corn, with very handsome foliage. Should this plant retain, when planted out in the border, its variegation through the summer, it will prove very ornamental.

We understand that at the fortnightly meeting to be held this day, Mr. Anderson, of Meadow Bank, Glasgow, will exhibit a magnificent spike of *Odontoglossum Pescatorei*, bearing upwards of sixty flowers, and which has been in blossom for the last three months.

A NATURAL BAROMETER.—Mr. Wm. McClathy, postmaster of Katesville, in West Middlesex, N.A., says, "As I know that you wish to give every information that would be of use to your numerous readers, I send you some remarks I have made on the changes which have taken place in the atmosphere for forty years past. I first observed in the rows of young Weymouth (or White Pine) trees in my nurseries, that the last year's growth and all the leaves or spines stand straight upright in dry weather, and on the least change to rain or snow the branches bend and the leaves fall back and appear in a dying state, even before the snow or rain commences. When a change comes for dry weather, they all recover again, and remain so until the next change is going to take place, giving the farmer warning in time for him to prepare for it. The White Pine (*P. strobus*) grows in this neighbourhood spontaneously. It is

easily transplanted, if removed when about a foot high. It soon makes a beautiful tree, and might be called the Farmer's Barometer."—(Canada Farmer.)

FRAGMENTS ABOUT THE INTERNATIONAL HORTICULTURAL EXHIBITION.

AZALEAS.

If anything could more strongly than another show the extreme absurdity of the present system of exhibiting Azaleas—a system against which for years I have entered my humble protest, it is the sketch given in a late number of THE JOURNAL OF HORTICULTURE of the interior of the Exhibition tent. And yet one knows that amongst the marvels of cultivation there were perhaps no plants in the whole Exhibition that bore greater testimony to the skill, care and continued attention of the gardener than did these masses of bloom; but surely these qualities are wasted in producing what I cannot but regard as deformities. Nearly every one says the same, and yet on the same track we go year after year. What is to be the remedy? Either one of two plans: Either the schedules must state that the plants are to be grown as naturally as possible, or else some successful cultivator must be daring enough to run the risk of losing his prize, and send in a collection naturally grown. This is what has occurred with Fuchsias. They used to be as much crinoided and twisted about as the poor Azalea was; but one day Mr. Cannell, to his credit be it said, entered the lists with a set not nearly so large as those of his competitors; and the Judges, equally to their credit be it said, recognised the courage and rightness of the attempt, and awarded it the first prize. Since then Fuchsias have been aerioided; and now that the veritable crinoline is going out of fashion and giving way to the train, will our great Azalea-growers follow in the wake, and give us plants equally well grown but not so much crinoided?

The great contest of the day lay in the class for eight plants between Messrs. Turner and Veitch; but the Judges had, I should imagine, little difficulty in coming to the decision at which they arrived, taking the present system as their model, for certainly never were such plants, I think, staged as those contributed by Mr. Turner. His plants were Perryana, Sir Charles Napier, Variegata, Criterion, Cheloni, Illustris nova, Barclayana, and Ivory. In none of these plants was there a single gap. Every portion was well filled up with bloom, and the individual flowers were also large and of good quality. Messrs. Veitch and Sons' plants consisted of Carnea superba, Trotteriana, Cheloni, Magnificent, Cedo Nulli, Juliana, Extranei, and Ivoryana. A third collection from Mr. Rhodes was of a very inferior description. In the class for single specimen Azaleas, Mr. Turner was first with a magnificent plant of Etoile de Gand, a most beautifully marked variety, and in every point a perfect picture. Messrs. Veitch were second with a good plant of Cheloni; and Mr. Carson third with a fine Sinensis.

In the very interesting collection of twenty plants Mr. Turner was also first with a varied collection containing some of the newest and finest varieties in cultivation, including Louise von Baden, Madame Ambroise Verschaffelt, Flower of the Day, Duchesse Adelaide de Nassau, &c. Messrs. Ivory & Son, of Dorking, took the second place. Their collection included some of the finest of their own varieties, as well as those of foreign introduction. Messrs. Lane & Son were third, and Messrs. Lee fourth. Amongst one of the improvements that might have been made in the arrangement of the Exhibition, I think that the sinking of these pots in the earth, so as to have formed a bed, would have been a very great one, somewhat in the manner in which the small plants of Rhododendrons were treated.

It was a wise and considerate measure to make classes which should comprise smaller growers, and so give them some encouragement; and hence very finely grown collections, which would not have made their appearance had these classes not been made, were brought forward, and in many instances the exhibitors received well-merited prizes. Thus, not only do we find that the Messrs. Lee, &c., were prizetakers, but that Messrs. Dobson & Son, of Isleworth, Mr. Baxendale, of Guildford, and Mr. Drummond, of Bath, were also successful, these being quite new names for this class of plants. Nor were the amateurs behind; some of their collections were indeed nearly, if not quite, equal to those of the professional growers. In the class for eight plants Mr. Carson, gardener to W. R. G. Farmer, Esq., of Cheam, had Formosa superba, Magnifica, Murrayana, Exquisita, Malvina, Speciosissima, Triumphans, and Broughtoni; and no exception could be taken to any of the plants, so well were they grown and flowered. Mr. Morse, gardener to T. Canning, Esq., of Bristol, was second with Gledstanesi, Etoile de Gand, Empress Engenie, Gem, Criterion, Speciosissima. His plants were differently trained from those of some of the other growers, being more pyramidal, but still having a great deal too much stiffness. Mr. Penny, gardener to H. H. Gibbs, Esq., and Mr. Peed, gardener to Mrs. Tredwell, two well-known names at our exhibitions, were respectively third and fourth. The same considerate measure was adopted in this class also, and had the effect of bringing forward names hitherto unknown at our metropolitan exhibitions. In the class for six Mr. Chalmers, gardener to E. J. Coleman, Esq., took the first prize with Præstantissima, Rosea punctata, Criterion, Gem, Lateritia superba, and Perryana; Mr. Wheeler, gardener to J. Philpott, Esq., of Stamford Hill, was second with Magnifica, Gledstanesi formosa,

Juliana, *Criterion*, *Symmetry*, and *Iveryana*; Mr. Ingram, gardener to J. J. Blandy, Esq., of Reading, third with *Glory of Sanninghill*, *Iveryana*, *Præstantissima*, *Rosa punctata*, Sir C. Napier, and *Criterion*. *Agnia*, for three greenhouse *Azaleas*, Mr. Kaile, gardener to the Earl of Lovelace took first prize; Mr. Kemp, gardener to Earl Percy, second; and Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, third prize. It will thus be seen from how many quarters exhibitions of this lovely and attractive spring flower were forwarded, contributing as they did so much to the splendour and beauty of the Exhibition.

Something has been said as to the manner of judging, and complaints made about it. I have had some little experience in such things, and I can only say that seldom have I seen fewer of what I believe to be mistakes; and that the plan adopted of breaking the Judges up into small knots instead of having a crowd of decorated gentlemen hustling one another, as at foreign shows, is infinitely to be preferred. I speak thus with entire disinterestedness, for I had nothing to say to it in any way. I pitied indeed many of them who had to hunt for this or that collection; but it was not to be wondered at that this should have been the case where so large a collection of subjects was brought together, and where, moreover, they were arranged more for effect than for the comfort of the Judges. Had it been imagined that the Exhibition would have been kept open for so long, it would have been better to have done as they do on the Continent—allotted Monday afternoon for the judging, and the plants to have been put in their places on Tuesday morning; but I would repeat it, that on the whole the adjudication was as well managed as could reasonably have been expected.—D., *Deal*.

COMPOST FOR FLOWER GARDEN—THINNING FLOWER-BUDS OF CLIMBING ROSES.

Is the refuse of a garden (leaves, grass, &c.), decomposed as good a manure as I can have for general use for flower-beds, or would it be the better of having stable manure mixed with it? Also, will it decompose more quickly if I keep it damp and mix lime with it occasionally to prevent its giving out any smell? I may remark that the heap is kept under trees where very little rain can reach it.

Will leaving many flower-buds on Roses prevent their growing? I allude to some climbers I have which I want to grow as much as I can this season to cover a space, and they seem making little headway, which I attributed to their having a good many buds on them; so, shall I remove them or allow them to remain and flower?—F. J.

[Grass and leaves mixed together make an excellent compost for a flower garden, and will decompose more rapidly if moderately damp. We would rather cover the heap slightly with earth than mix lime with it to keep down the smell. For Roses and other plants that like rich food, a mixture of horse or pig dung along with the above compost will be beneficial, and even in any circumstances a little will improve your compost; but for flower-beds in general, decayed tree leaves and grass do very well. We advise you to thin the buds of your climbing Roses that you wish to grow vigorously.—Eps.]

BIRMINGHAM ROSE SHOW.—The prize list for this great midland gathering, which is to be held on the 5th and 6th of July, differs in but few particulars from last year's. The most striking alteration is in the nurserymen's class, and consists of the reduction of ninety-six varieties, single trusses, to seventy-two varieties—a decided change for the better, and one which will be certain to produce an improvement in the quality of the stands shown in competition for the premier prize of the Exhibition. No. 5, twenty-four varieties, single trusses, and No. 6, twelve varieties, three trusses, are reserved for nurserymen resident in the counties of Warwick, Worcester, or Stafford only. These, as well as the other purely local divisions, are yearly increasing, and now form a very important feature. To local residents they must be particularly interesting and instructive, for in the local stands information must be sought as to what varieties have proved most available in the neighbourhood, and at the same time comparisons may be made between the appearance which the same variety presents as grown in widely different localities, under circumstances of climate, soil, &c., totally dissimilar. Bouquets have hitherto always been too large and formal. The Committee, with a view to make them smaller and less crowded together, intimate that it is essential that they should be suitable for the hand, and suggest the free use of *Noisette*, *Moss*, and *Tea-scented* Roses in a just-opening condition. We trust that on this occasion the weather will be more propitious than last year, for in consequence of the exhibition days having been

wet, the expenses exceeded the receipts, and the balance had to come out of the pockets of the Committee. We learn with surprise that out of 300,000 inhabitants, only 200 subscribe to the Rose Show. This should not be.

PEAT CHARCOAL FOR PRESERVING FRUIT.

FINDING so much pleasure in the perusal of your Journal, and having experienced your courtesy as a correspondent on more than one occasion, I am tempted to offer my little mite of experience for the good of other readers.

Having year after year used without success every care to keep Apples fresh till spring, it occurred to me last autumn that I would try packing them in peat charcoal. The result has been so eminently successful that I had my Apples crisp, fresh, and juicy, as if pulled off the tree, till a few days ago when I had my last dish. I used to keep them till April or even May, but they were shrivelled and insipid. The kinds I usually put by are *Ross Nonpareil*, and an Apple of which I do not know the name, but it closely resembles the *Ribston Pippin*. I lost some by packing too much in the boxes, or by piling the boxes above one another to economise space.

It strikes me that collectors of foreign bulbs, &c., would find the charcoal a great preservative against decay from the moist sea air. I have had presents from the Cape of bulbs, and always found the roots so damaged as to be of little value. The only objection to the charcoal for Apples is that they must be washed after it.—A SUBSCRIBER.

THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.

Edited by the Rev. M. J. BERKELEY, F.L.S., &c. New Series. Vol. I. Part 2.

THE Society commenced publishing a Journal in 1846, and continued doing so until 1855, when financial weakness obliged its abandonment. That weakness being removed, and the Council being conscious that the Fellows were entitled to have not only a record of the Society's proceedings, but of the discoveries and improvements in horticulture effected in other countries, have revived the Journal, and it bears evidence at once that its preparation is confided to an editor not only well known for competency, but, which is as important, judicious and painstaking.

There are in the two parts which have been published a very satisfactory combination of the practical and scientific communications; the practical are not trivial, and the scientific are not too elaborate—all contain information useful to plant-cultivators.

As an example of the practical contents we extract the following:—

“ON *PODOPHYLLUM EMODI*. By Mr. Thomas Shortt.

“*Podophyllum Emodi*, Wallh.* (*P. hexandrum*, Royle), is found in Sikkim, Kumaon, and Cashmir, at an altitude varying from 6000 to 14,000 feet, and is one of the earliest spring flowers of the Himalayas. Particular interest is attached to this plant from its first appearance above the ground to its decay. The first growth of the plant is very curious, the centre of the leaf appearing first; the leaflets or segments of the leaf are plicate and folded downwards on the petiole in bud, and the whole plant has much the habit of *Eranthis hymalis*†. After two or three leaves are developed, the flower appears in the axil of the upper leaf, and, to a casual observer, is much like that of *Helleborus niger*, though smaller. When first opened it is of a delicate blush, and when fully developed is of a pure white.

“The flowers are rather fugitive and, if fruit (which is both interesting and ornamental) is required, must be carefully watched and artificially impregnated as soon as the pollen is exposed. This generally takes place on the morning of the first day. A very few days will show when the fruit is set, as rapid increase of size indicates success. The fruit remains green to within a few days of ripening, when it is suffused with a delicate pink, which gradually changes to a deep scarlet, covered with a delicate bloom. A well-matured fruit is drooping, egg-shaped, and flattened, $3\frac{1}{2}$ inches long and $1\frac{1}{2}$ inch thick, the stalk being inserted at the broad end. It is pulpy, tasteless, filled with numerous seeds about the size of wheat when in a milky state, and of somewhat the same form, which are attached to a broad fleshy lateral placenta which occupies the centre of the fruit.

“The fruit is eatable, like that of *P. peltatum*, whose leaves, however,

* Beautiful specimens of this plant in fruit were exhibited at one of the scientific meetings by Mr. Shortt.

† This and one or two other sentences are borrowed from Hooker and Thomson's 'Flora Indica.'

are poisonous and the root a drastic purge; it will hang one or two months. That of *P. peltatum*, which is known in the United States under the name of May Apple, is of a peculiar light green colour, and is intensely acid. It is occasionally used as a substitute for Lemon.

"No plant that I am acquainted with is more impatient of removal or division than *Podophyllum Emodi*. I was some years before I discovered the cause. On potting some seedling plants two years old, I found only two thread-like roots from 2 to 3 feet long, and when these were shortened before repotting, no progress was made by the plant that year. When, however, the roots were unbroken, rapid increase of size took place.

"To grow the plant in perfection, it should be planted in good peat and loam in an open but sheltered situation and never disturbed. If moved, it will not bear fruit the following year. It is perfectly hardy, and was introduced in 1815."

The scientific contributions are too lengthy for extraction, but the combined results announced in two of them are of great interest to plant-cultivators, and command from us an epitome. As long ago as 1900 years, Varro records that the Roman husbandmen supplicated a goddess of their polytheism to preserve their corn and trees from *rubigo*. This was that disease which we know as the rust, for Virgil particularises *rubigo* as afflicting the straw. We could quote other authorities in proof that it was then the received opinion that the *rubigo* of corn was identical with the parasitical diseases of trees, but it is only now that the truth of this opinion is demonstrated.

It has long been an observation that where the Berberry abounds there mildew commonly affects the Wheat crops; and years since we were shown a Berberry bush in a hedgerow, and a breadth of Wheat affected by mildew extending across the field from that bush, whilst no other part of the field was so affected; and we remember a Berberry-abounding village in Norfolk bearing the unenviable title of "Mildew-Rollesby." That the mildew on Wheat and the parasitical fungus afflicting the Berberry are identical has been denied by excellent authorities, and fungolists have sustained the denial by naming the Wheat fungus *Puccinia graminis*, and the Berberry fungus *Æcidium Berberidis*, but M. De Barry has shown that it is one and the same plant, in different stages of development; in one stage it will only vegetate on the Berberry, and in the other on the culms of Wheat and other Grasses. Nor do the discoveries tend to reduce the number of fungal genera stop here, for M. Oerstead has given evidence that, also in different stages of development, the fungus *Podisoma Sabinae*, which lives on the Savin, *Juniperus sabina*, is the same as *Ræstelia cancellata* which attacks the leaves of Pear trees. Nor do these discoveries stop here, for M. De Barry has shown that *Uromyces faba* which infests the leaves of the Bean is only another form of *Æcidium leguminosarum* found on the same plant.

A PEEP AT THE WOODS IN ODD PLACES.—No. 7.

CUBA.

(Continued from page 442.)

HAVING heard the band play, let us leave the sweet odours wafted about the square opposite the palace of the Captain-General, and proceeding on our rambles take a look around us as we wend our way towards the fruit market, a peep at which will amply repay our curiosity, and afford us some pleasure. Before proceeding on our way, what, we must ask, can those strange spider-looking things on two wheels be? They are called *volantés*, and are the national passenger-conveyance, being used in the place of our cabs, though, of course, the four-wheeled hackney carriage is likewise common; but this is the native trap, and although presenting such an extraordinary appearance to an English eye, is exceedingly comfortable and easy to ride in. I will, however, try to give you some notion of them, for they are worth mention, and some of the private ones are most gaudily got up, though they do present much of the appearance of a huge gilded and burnished spider. Two high but light wheels, on their axle-tree, are placed at the extremities of two excessively long springy shafts; between these, suspended by straps and C springs, is hung rather than fastened, but yet sufficiently firmly fixed to prevent too much swinging motion, a body somewhat resembling that of a Hansom cab, but lower and longer, and the back of which is about 3 feet from the axle. In this lies, rather than sits, the passenger stretched at his ease, with his feet resting against a little iron rail placed inside the dash-board, whilst he is protected from the sun or rain by the hood overhead. In the shafts, with his

tail fully 4 feet beyond the board, is a horse or mule, as the case may be; and on his back, in a most preposterous saddle, with a very high pommel and crup, is seated the driver, often a nigger, dressed in a tall hat, jacket, breeches, and huge boots, the heels of which are armed with as huge spurs, and carrying in his hand a formidable whip. The length of the whole affair, including the horse, will be from 20 to 25 feet; and as the streets are very narrow, it is requisite to go to the intersection of two streets to enable the driver to turn his vehicle. Those belonging to private persons of means are, as I have said, often very expensively got up, most of them silver-mounted, both as to the *volanté* itself, and the harness, and sometimes the ornaments are of silver gilt. For such vehicles two horses are used, one being in the shafts, and the other ridden by the postilion, who leads the horse in the shafts.

If, however, we stop so long looking at these, to English eyes, extraordinary conveyances, we shall never reach the fruit market, to which place we are bound; only as we are just opposite *Dominico's*, we will step in, and sit down to rest ourselves, and look about us for a few minutes, whilst we take a little refreshment before we walk on, since the weather is extremely hot, and we have some distance to go beyond the walls of the city. *Dominico's* is a restaurant, and really a most beautiful and delightful place, where one may obtain any delicacy he wishes for, from English ale (there a most expensive luxury), to Guava jelly, manufactured on the premises; so call for what you like—coffee or claret, champagne or chocolate, soup or sardines, cigars or cakes, hobsens or Bananas, and whilst you are resting, I will try to give you some notion of the place. In a narrow street not more than 12 or 14 feet wide between the curb stones, and with no footpath to speak of, for that in any street of the city is seldom, indeed scarcely ever, a yard in width, and where the houses run straight up, presenting a most gloomy prison-like appearance, stands this palace of Epicurus, cool, fragrant, and pleasant. We enter by an arched gateway into a somewhat spacious hall. The floor is of black and white marble; the roof, which is beautifully painted and gilded, is arched, and supported by a number of marble pillars, from the capitals of which spring the groins of the arches. In the centre, as in most of the large houses of Havana, is a square open to the sky, and likewise paved with marble, in which is an elegant fountain; planted around the pedestal of which, and mingled with lovely specimens of coral and effigies of water sprites, are Ferns, small Palms, especially the Palmetto, and wax-leaved tropical plants, most exquisite Moss filling up all the interstices with the greatest luxuriance; whilst in the basin below surrounding the fountain, and playing about in and on the rockwork at its base, swim with much apparent enjoyment and appreciation of the jolly company around them, numerous gold and silver fish. In the hall and square stand a number of iron-framed, marble-topped tables, around which may be seen seated various groups, silent or noisy, in sober conversation or sprightly chat, consuming the various dainties here obtainable. These persons are composed of various nationalities, generally showing by their manners, tones of voice, and action, as well as language, to what flag they may have the honour to belong. Here are to be seen the lively, chatty Frenchman; the sombre, stately Don; the phlegmatic Dutchman; the swaggering, boasting Yankee; and last, though decidedly not least, the conceited Englishman, who, if not in so many words, at least in manner, treats the natives of whatever country he may be in, as inferior creatures; in fact, Englishmen generally, in their own estimation, are not foreigners, whether in the Arctic regions, the temperate or the torrid zone, amongst Esquimaux, Black-foot Indians, Europeans, Ashantees, Hindoos, or Madagascans; but they all, at any rate by far the greater part of them; seem to consider that they have a universal kingdom, and are, like Robinson Crusoe, "monarchs of all they survey."

Our own party in this hall was by no means an uninteresting one, being comprised of seven persons, representing five distinct nationalities and one colony, each being fairly, indeed favourably, represented. Of Englishmen, there were the captain of our vessel and myself; from New Brunswick, a tall, elegant, exceedingly gentlemanly man, who formerly held a high position under the crown in the colony, and was of decidedly Tory and aristocratic tendencies; from France, an ex-consul, thoroughly French, and a thorough gentleman; from the Southern States of America, a large cotton-press and plantation owner, belonging to New Orleans; from Prussia, a tall, fine-looking man of about thirty, who had fought on the Southern side in the late American war, and had in a most courageous manner saved a large amount of treasure, which the Federals

attempted to seize and appropriate; and from Denmark, an enormous merchant captain, who had sold his vessel, and was returning to Copenhagen. He was a man of immense size and strength; his good humour and fun were equal to his bulk, and although acquainted with many Danes, Swedes, and Norwegians, I have never met with one so completely the impersonation of one's idea of the old Norse Viking (*i.e.*, in appearance only, for his body was large and powerful, his heart was truly womanly, noble, tender, firm, soft, and true), robber, pirate, and conqueror, or of the grand old Saxon mythological deities, Thor or Woden. I can only say we were a very merry jolly party.

We will leave the cool shades of Dominico's, and turning out into the broiling sun, plod on our way towards the fruit market. Having proceeded some half a mile or so we come to a gateway in the wall; passing by the guard we go over a bridge which spans the moat, and following a broad, very dusty road pass the large and roomy theatre and come to a sort of parade-ground, where we see drilling a number of troops, somewhat small and awkward, but looking on the whole clean and neat, though most decidedly not formidable; and an Englishman by comparison, could not help thinking, proudly, of "The Guards," at home.

Having crossed over this parade-ground, which is surrounded by a high iron railing, with a gateway on each side, we come to a new town or suburb, and passing up one of the streets we turn sharply to the right and enter the fruit market, and, oh! what lascivious temptation do we here see exposed on all sides; and I for one must really say that I can almost excuse, and certainly do not wonder at, Eve's transgression, if the Apple with which she was tempted was one half as beautiful as many of the fruits here displayed for sale, and the only objection to which is their bewildering variety. In every direction are seen, on stalls, under stalls, on the pavement, and in baskets, fruit, vegetables, and flowers, though the latter, I grieve to say, do not seem to hold anything like the position in public estimation which, from their sweetness and brilliancy of colour, they should do; but I suppose the old proverb, "Familiarity breeds contempt," stands good or bad here as elsewhere.

One of the first and most conspicuous fruits, both on account of the size of the bunches and its utility, is the Plantain. This is used both green and ripe—when it is of a dull brownish yellow. It is generally cooked and made into fritters with batter, and is superior to any fritter I know, neither Apple, Quince, nor Peach being comparable to it, for before its peculiarly delicate mellow flavour even the luscious Pine Apple must succumb—*i.e.*, when cooked. Next comes its delicious first cousin the Banana, which is a much shorter and smaller fruit, although, to a certain extent, like the last, both much resembling in shape a sausage which has been squeezed until it has become triangular instead of round. There are two kinds of Banana—the light yellow and the red, which latter is generally much the sweeter, though drier than the other, and both are in flavour much like a mellow Pear. Both the Plantain and Banana grow on a tree, or rather plant, with a very long, broad leaf, and the difference between the two plants is rather a puzzle to the uninitiated.

Next in importance in the fruit line to the Plantain and Banana come Oranges, which are most abundant and cheap—that is, if you know how to bargain for them, for even in this out-of-the-way spot the natives understand the noble art of "chiselling" or cheating a stranger. Here we likewise see Pine Apples and Pomeles (I beg pardon, that is the Bengalese name for them), here they are called Shaddockes, and in England Forbidden Fruit, I suppose on account of the bitterness with which their otherwise sweet and delicious juice is mingled. They are a large fruit, often as much as 5 inches in diameter, of the Orange tribe, the flesh of the sweetest and best being pink. In Calcutta they could be bought in any quantity for a pice a-piece, a pice being the fourth part of three-halfpence. Then come Grapes and American Apples, and nuts of various kinds from the mighty Cocoa-nut downwards.

As for vegetables I can hardly say much; but I noticed Cabbage and Turnips, common Potatoes (here called as in America), Irish Potatoes, and Sweet Potatoes, several kinds of vegetables and Beans to me unknown, and plenty of Sugar cane. My space, however, warns me that I must stop, and although I would have been delighted to have taken you to that wonderfully brilliant marine garden, where Amphitrite's most precious scaly flowers are exposed to view in all their richness of purple and gold, silver and black, bright scarlet and yellow, and other vivid colours too numerous to mention,

and only to be understood by being actually seen—I mean the fish market, and likewise to mass at the curious old cathedral, I must drop the curtain o'er the scene and make my *congé*.—
A STRANGER.

TOBACCO CULTURE IN ENGLAND.

For the convenience of those persons who, like your correspondent "P.," are unable to refer to the Acts mentioned by "W. C." (page 416), I have hereunder set forth so much of the penal clauses in the Tobacco Acts as will help to guide them to the right view of the subject.

Section 3 of the Act of 1831 (1 & 2 William IV., c. 13), explains how the several penalties and forfeitures imposed by the Acts passed in the twelfth and fifteenth years of the reign of Charles II., or by the Act of 1831, or any other Act prohibiting the growth and culture of Tobacco, may be sued for, recovered, &c.

By the Act (12 Charles II., c. 34), "a penalty is imposed for every rod or pole of ground planted, and so proportionably for a greater or lesser quantity of ground;" and by 15 Charles II., c. 7, the penalty was increased, but the same words again occur—"proportionably for a greater or lesser quantity."

Moreover, there is a penalty on having Tobacco (exceeding 1 lb. in weight), the growth of the United Kingdom, in possession, &c. (see page 287).—X., Surrey.

NOTES FROM JAPAN.

To the west and north-west of Yokohama, at a distance of about twenty-five or thirty miles, is a range of mountains, a portion of the great range that extends itself across the Island of Nippon to the western coast. The eastern termination on the plains at the head of Odawara Bay is an abrupt peak, styled Oyama, a sacred mountain, the residence of an evil spirit, to whom an idol is erected on the summit, and to which, at a certain season only in the year, pilgrimages are made.

A large section of the country between the hills and valleys of the coast is an elevated plain, which extends many miles into the interior, and mainly cultivated with the Mulberry for the production of silk, the chief source of wealth to its inhabitants. The town of Haechoji, situated in a large valley that intersects the plain near the base of the mountains, a trifle beyond the strict limits to which foreigners are permitted to travel, is the centre of a large silk trade, and of considerable commercial importance; it is not unfrequently visited by parties from Yokohama.

To make a visit not only to Haechoji, but a tour through the country to Oysma, had long been my desire, but it was not until last summer and autumn that opportunity presented itself, when I had the pleasure of twice doing so, on foot and afterwards on horseback.

My first journey did not extend itself as far as Haechoji, which I visited on my second trip, and otherwise varied in direction from the second. The possibility of a pedestrian tour had frequently been the topic of conversation between myself and several friends, until at last we decided to try it. On the morning of September 5th we started off, accompanied by two attendants to carry necessary baggage and provision, and took the road direct to the mountain. After passing over the Tokaido several miles, we turned off into a broad and fertile valley, gradually ascending until we reached the table land. Our course laid directly over the plain, meeting numbers of pilgrims going to and returning from Oyama. We soon met with Mulberry trees, our road passing through an almost continuous plantation of them. The point at which we ascended the plain is about the lowest towards the sea, some eight or ten miles distant, at which the Mulberry is cultivated; beyond it gradually descends into a lower plain cultivated with cereals. Occasionally we would descend into a small valley, in which places the population chiefly reside, but where the Mulberry is no longer cultivated. It is characteristic of the people to choose valleys and retired shaded nooks for their residences, and the absence of inhabitants on the plains was a marked feature of our journey. In a few instances we met with villages not in valleys, but they are rare exceptions to the general rule. In the afternoon of the day we passed through one of these, which, with its broad street in the middle of it, reminded me of those seen in other lands. Still later in the afternoon we descended into a valley through which flowed a rapid stream called the Sangami river; at the time we crossed it was but a narrow stream not over 150 yards

in width, but the wide extent of large pebbles and gravel on either side was an indication of the volume of water and force of its current in the rainy season of the year.

As we approached Oyama the land became more undulating, until at last we reached the village of Koyasu at its foot, and sought lodgings for the night, which, after some delay, were procured. We had proposed to ascend to the summit of the mountain the next morning, but our intentions were thwarted by a guard of officers stationed at a large gate on the road to prevent the intrusion of obnoxious persons: they were very firm and decided in their refusal to permit us to proceed, and there remained no other course for us but to return homeward. Our route lay up an extensive valley running parallel with the mountain range, between which was a range of high hills separating another smaller valley on the other side of them. We ascended one of these hills, where we had a fine prospect of the whole country before us. The mountains before us were so near that we could plainly discern their features. They are very rugged and precipitous, divided into many sharp ridges, extending from their summit to the base, and only partially covered with forest. In this respect they much resemble the mountains of Lower California, as seen from the sea on sailing up the coast. This resemblance of the mountains generally of Japan with those of that country has been remarked by others who have had the opportunity of observing both, and would point out their common volcanic origin. The vegetation of the country was very similar in character to that of the neighbourhood of Yokohama, the greatest novelty being a species of Hydrangea, or an allied genus, found growing on the banks of a stream of water. I had previously found it cultivated by the gardeners of Yokohama, and already sent it home.

After following the valley several miles, the road suddenly led up to the table land again, and once more we were among Mulberry trees. The unvaried character of the landscape, only relieved by the mountains on our left, combined with the heat of the day, rendered our journey rather wearisome, and I felt glad when, in the afternoon, we made a sharp descent from the plain into the valley of the Sangami, and sought refreshment at an inn on its banks. The declining sun after a while admonished us to proceed on our journey to our proposed stopping place for the night. The next morning our road still continued over the plain and between rows of Mulberries. The manner of planting them is by laying out the ground either in squares 80 to 100 feet on either side, or in larger sections of 100 to 200 feet in depth, the trees being planted on the margins at a distance of about 6 feet from each other, forming an enclosure, inside of which are cultivated various crops—Sweet Potatoes, Taro, Beans, Upland Rice, Buckwheat, &c. In cultivating the trees, the system pursued is to confine them to a stem to the height of about 4 feet, and then allowing them to branch off to form a head. When feeding the worms the leaves alone are not gathered, but the shoot of the previous year with all the fresh leaves on it is cut off close to the main stem; and when all are cut off the tree is left to produce new shoots for the succeeding year. In process of time, by this yearly close pruning, the top of the tree becomes a thickened mass of spurs, but without any apparent diminution of vigour in the tree to throw out new shoots. When first planted they are not subjected to this treatment until four or five years old. They endure the process many years before they show symptoms of decay, and when this begins a new stem is allowed to start from the root, and eventually the old one is cut out.

Subsequent to my trip, I was informed that in other parts of the country the practice is not to allow the Mulberry to form a main stem, but to cut the shoots off close to the surface of the earth. The soil in which they grow is light and black, not retentive of moisture, and can be supplied with but a small amount of fertilising material owing to the extent of cultivation, the comparatively great distance from the habitations of men, and the necessity of its use to other crops in the valleys. The crops, too, within the boundaries of the trees were not heavy, and showed an evident want of manure by the very limited amount of yield. The almost entire want of cattle, except pack-horses, contributes greatly to this want and consequent decreased production of the soil. The division of the land into small sections, and the mode of planting the Mulberry around them, entirely preventing the application of any but manual labour, must also operate against increased production.

During the last day's walk we were surprised to meet, in several places, extensive plains of uncultivated land covered with short grass and a few dwarf bushes. Their exact area we could not ascertain; but one of them, the largest we crossed, was two or

three miles in width, and more in length. A part of one of them was covered with a dense growth of shrubbery, and it is probable they all had been similarly covered at some former time; small portions on their margins were being gradually brought into cultivation.

In the latter part of the journey the size to which the Persimmon trees grew attracted our attention. Instead of being confined to farmyards they were growing in the open fields among the Mulberries. Whether they were grafted fruit I am unable to say, but I had never before seen any so large, and their dark shining leaves rendered them quite ornamental.

In the afternoon we struck the head of a long valley leading towards Yokohama, reaching our homes in the evening, somewhat wearied by our walk of over sixty miles, and amply rewarded by the new scenes we had witnessed.

My second trip, as I have before stated undertaken on horseback, presented very little of horticultural interest beyond the first. I observed, in a few places, the Mulberry planted in rows by some innovation on time-honoured custom, even in this land of fixed habits. I also met, in many places, growing by the side of watercourses, a very beautiful annual Balsam with large flowers of a fine purple colour. It appeared to me quite new, and I have transmitted seeds of it home, where, I trust next summer, you will be able to judge of its merits yourself.—T. Hogg (in *American Gardener's Monthly*).

WORK FOR THE WEEK.

KITCHEN GARDEN.

If former instructions have been carried out, this department will now present many agreeable features. Continual hoeing, forking, and surface-stirring, together with a favourable season, have told well upon the crops, which are abundant and vigorous. All these operations must be diligently persevered in: the advantages derived therefrom are manifold—weeds are exterminated, slugs are disturbed and destroyed, moisture retained at a time when it is most needed, and a healthy relation kept up between the roots and the atmosphere, which last is the principal cause of the success which follows these operations. Trenching vacant ground must be preceded with where required; and if manure is wanted on ground about to be planted, it is best to lay it on the top after it is trenched, and then fork it in. Let all green refuse be removed from every part, and be either dug in or taken to the char-heap. *Asparagus*, be chary of taking too much from the main beds now; it is best to have a reserve bed, which, if closely cut, will throw up shoots for a considerable time, and as it will thus be rendered useless, a new bed should be made every year to supply the deficiency. *Brussels Sprouts*, plant out the most forward, as also *Green Savoys* and *Buda Kale*; if the weather is dry the holes had better be puddled. *Cauliflowers*, plant out for succession. *Cucumbers* on ridges and banks must have plenty of water, and liquid manure occasionally. *Dwarf Kidney Beans* may be sown for succession. A sowing of *Early Mazagan Beans* made now in an exposed situation will be useful by-and-by. *Peas*, sow *Knight's Marrows* and *Early Frame* for succession; these are benefited by a slight soaking in water previous to sowing, and also by pouring water upon them after they are laid in the drills, but not after they have been covered. Advancing crops will be benefited by applications of liquid manure, not too strong, twice a-week. See that the ground is kept well stirred about them. Continue the gradual thinning of *Carrots* and *Onions*, as they may be required for use; but *Parsnips*, *Red Beet*, *Salsafy*, and *Scorzoneria*, should always be thinned to the proper distance at once. *Salading* of all sorts is now in great request. Look well to successional sowings, and see that they all have copious supplies of water to induce crispness and coolness. *Scarlet Runners* should have the earth well loosened about them, and a little drawn up to the stems; then stake at once. *Sea-kale*, the buds on the old roots must be thinned out considerably, and dress the beds with strong manure, and fork it in. Young seedlings of *Sea-kale* must also be thinned, and the thinnings transplanted if required. Keep all advancing crops in a vigorous growing state, by timely applications of water in dry weather. Watering should never be done by dribbets, here a little and there a little, but every crop should be thoroughly soaked. The practice of giving little drops every day cannot be too much avoided; a thorough watering once a-week will do more good than the same amount of water distributed through each day.

FRUIT GARDEN.

Employ the engine against the aphid on fruit trees as soon

as it is detected. The injury it inflicts on the foliage, although, perhaps, not immediately perceptible, is no less certain; the perfection of the bearing wood, and the perfect development of the buds for the ensuing year, are dependent on a healthy development of the foliage. Employ sulphur on the appearance or suspicion of mildew. Continue to step, regulate, and lay in the shoots of wall trees. Stop the Vines, and tie in the shoots, one bunch is sufficient for a single shoot to support. Thin Raspberry suckers. Water late Strawberries. The plague of caterpillars is again appearing on the Apple trees; to prevent their ravages we would advise the use of a powerful engine to dislodge them, or a good heap of refuse to be collected on the windward side of the trees, and a great smoke created, which would have a good effect, as it would be fumigating on a large scale.

FLOWER GARDEN.

Examine all newly-planted things, and see that the soil is closed about their stems. Use the hoe, when requisite, to break the surface crust. Attend to pegging and tying. Fill up all vacancies; annuals may be brought into requisition for this purpose. Roses may be budded, taking eyes from those trees which have been forced; the young wood from the same trees will strike freely. This is a good time for looking over lawns and removing objectionable weeds. The regulation, so far as is necessary, of wild creepers, such as Honeysuckle, Hop, &c., about shrubberies, should at once be attended to. For the first season or so, Pinuses planted on mounds should be regularly watered and mulched. Peg down those plants required to cover the ground as they advance, and loosen the surface of the beds and borders, which should afterwards be neatly raked over. Carnations, Picotees, and herbaceous plants, with the taller-growing bedding plants, should be staked and tied up to prevent injury from high winds. The strength and height of the stakes must be proportionate to the size and height of the plant to be secured. Hollyhocks, Phloxes, Delphiniums, Asters, &c., should have the shoots thinned out, if not already done, before being tied up to prevent the appearance of overcrowding, as well as to improve the size of the flowers. When showery weather occurs let the Box edgings be clipped. London Pride, Thrift, Daisies, &c., used for edgings, should each year, or once in two years, be taken up, divided, and replanted when the blooming time is over.

GREENHOUSE AND CONSERVATORY.

Specimens and choice plants nearly done blooming should have the faded blooms picked off, and be well washed with the syringe; they should then be placed in a cool, shady situation to recover themselves before potting, which, as before advised, should on no account take place until a fresh growth has commenced. Shading will now be necessary for all descriptions of plant-houses, unless the roofs are covered with creepers; and air should be admitted largely, allowing more or less at night, according to the description of plants grown. The paths, floors, &c., must be kept damp by throwing water repeatedly over them, to preserve something like humidity in the atmosphere of the houses, which, under the extreme drying of the external air, is rather difficult to keep up. Achimenes, Gloxinias, Gesneras, &c., should, as they begin to show for bloom, be removed to more airy quarters, keeping them, however, partially shaded for a time, but afterwards they may be exposed to a larger share of light. Achimenes must be carefully attended to with water while growing. Encourage the growth of Azaleas and Camellias by keeping them comparatively close (with shade during sunshine), and supplying them liberally with moisture through the syringe. As probably increased room will be obtained by the removal of many plants to the flower-beds, the space might be appropriated to the cultivation of plants of the commoner sorts for an autumn display. The pits will be found useful for many hard-wooded greenhouse plants impatient of too much heat. This is a good time to increase Chrysanthemums. The flowering of many varieties of the Passion-flowers will be hastened by stopping the young shoots, and any shoot which may be hanging too low should be stopped, which will prevent confusion and induce the production of flowers. Rearrange the plants frequently, and in the conservatory displace any that incline to become shabby.—W. KEANE.

DOINGS OF THE LAST WEEK.

WATERING.—The rains were followed by some of the hottest and most drying weather we have experienced. A falling barometer led us again to expect rain, but it was very loth to

come, and many fresh-planted things in the kitchen and the flower garden showed signs that they wanted a little more refreshing than a skiff over the foliage, which was all they had received in the parching days. On Tuesday the rain came in drizzle, but not in sufficient quantity to do more than refresh the foliage; and therefore, though some would say we were acting inconsistently, we set to work and gave the most of the fresh-planted subjects a little water. We held that that watering, whether followed by dull or by bright weather, would do more good than half a dozen waterings in dry, parching weather in sunshine. Some will say, Why water at all in bright sunshine, why not wait until the evening? All very true, when water is close at hand, and there are only a few yards or a score of plants to water; but it is a very different affair when you must take water as you can obtain it by horse and cart, when what really is within your possession must be carried or wheeled a considerable distance, and when the quantity required is so great as to demand the services of a number of men to apply it efficiently, and many of these men want the evenings for attending to their own gardens at home. Under such circumstances we have often been glad to water even in a bright sun, either wetting as little of the surface soil as possible, or going shortly afterwards either to stir that soil or scatter some of the dry earth over the watered part so as to prevent the sun carrying off the water again by rapid evaporation.

Now, in giving as much water as would reach the roots of the plants on Tuesday, none of it would be lost by evaporation; the clouds and the drizzle wrapped the tops of the plants in a moist atmosphere, from which they would absorb more than they perspired—roots, leaves, and stems would all be nourished and refreshed simultaneously. The roots would absorb at their leisure, and be prepared thoroughly to meet the demands of the bright sun when it came, and after such hot days both the earth and the water would be well warmed, so as to stimulate the plants as if they were in a hotbed. It is seldom that even rains would be so warm as the water was in the beginning of the week, that had been fully exposed in tanks or ponds. For such watering, at such a time, we believe, therefore, there are sufficient reasons.

Waterings of this kind, however, should never be overdone. No more water should be given than will just reach the roots and enable them to push vigorously, and cater moisture for themselves. We have little faith at any time, and no faith at all, in heavy drenchings of the soil now, and especially for tender plants, as the wetter the soil the colder it will be made when there is a rapid evaporation. On this account alone it is often best merely to water so as to refresh the roots, and leave the surface comparatively dry. At an early period, and for tender plants, the obtaining of heat and the retention of moisture often become antagonistic to each other, as, if we stir the surface soil, or mulch it to retain the moisture, we also so far prevent the earth from being warmed by the sun's rays. On this account it is often advisable not to stir the surface soil much until the earth is well warmed. We often defer doing it for tender plants until the surface begins to crack. The stirring the surface allows the heated air to penetrate into the soil, and this often produces striking results; but the rougher the soil is left on the surface the more will heating downwards by conduction be arrested. In hot weather in July we have found a difference of from 3° to 5° in favour of a thermometer 6 inches below the surface of a hard smooth gravel walk, over another 6 inches below the surface of a piece of ground often stirred on the surface. On the other hand, what keeps heat out will also keep heat and moisture in, and, therefore, surface-stirring and mulching are pre-eminently useful after the ground has been warmed and as autumn days become shorter. Until the ground is warmed heavy drenchings with water, and even frequent surface-stirring, are attended with a minimum of advantage.

In writing the above as constituting more than an excuse—an argument—for watering plants out of doors when they need it, in dull, drizzly, rather than in hot sunshiny weather, we depart nothing from the principles of watering frequently advocated, summarised in the directions, Do not water until water is needed; then give enough to moisten every fibre, but little more; and then wait patiently until your services are again required, avoiding by all means the system of moistening the surface by dribbles, which, in general, does more harm than good, tempting the rootlets to come to the surface, where they run the risk of being scorched and encouraged alternately, and so far preventing the roots going down in search of moisture, or receiving a share of the moisture that would pass

them in the shape of vapour, when there was to a considerable depth a continuous radiation of heat and an unbroken evaporation of moisture.

There is just one general exception to the above rule. In the case of newly-potted plants in the houses or otherwise, or of newly planted-out subjects, such as bedding plants now, the plants will often suffer from a hot sun when there is plenty of moisture at the roots, and dashing on more water could be of no benefit whatever, as the roots as yet cannot absorb fast enough to meet the sudden demands of sun and wind, as these take moisture away from the leaves and stems. Checking evaporation by shading until the plant has established itself would be better than drenching and cooling the roots. In a large way this shading would be next to impossible, and syringing or sprinkling overhead is often as effectual, and the ground is not cooled by the shading. In very hot weather we thus often give a dewing from the syringe and the garden engine, instead of pouring water from the water-pail, and the little that falls on the hot ground under such circumstances keeps, until it is entirely evaporated, a moist vapour about the leaves and stems which prevents them from flagging. A very little water will go a long way in thus damping the foliage, and so long as the leaves are damp the sun will rarely absorb the more valuable moisture contained in the plant.

We have no hesitation in thus treating our newly-planted bedding plants in the brightest sun if they need it, and an active man or lad will soon go over a large space. We know there are many who counsel us to avoid all this, as the plants and leaves would run the risk of being scorched and blanched. In practice, in the open air we have never found such an injurious result. Who is there that has found the prejudicial effects of what is called even a heavy sunny shower? We have never found a single burnt hole or blanched leaf after such a refreshing shower, with the sun making the most beautiful rainbows, as it shines brightly on the falling drops. Out of doors we have never seen anything injured by our slighter artificial shower, more properly called misting or dewing. Even under glass there is no great danger from such syringing, even in sunshine, if you are sure of clear good glass, and there is a free current of air through the place. It is the confined air, and the confined vapour that accompanies it, that are the chief causes of the mischief that sometimes takes place under such circumstances. This reminds us of several inquiries as to how to give to plants and cuttings the misting or dewing to which we sometimes allude. What we mean is, that the water shall be driven from a syringe or garden engine in such a fine form as more to resemble a misty dew than a common shower of rain. The art of doing so must be acquired by the workman, and then nothing is more simple.

There must have been few at the late International Exhibition that did not admire the many sorts of bends, and joints, and nozzles, and roses that could be attached to syringes and engines for throwing water, as exhibited by Messrs. Read and Warner. These gentlemen, we are sure, will excuse us for saying that a great portion of these mechanical conveniences are useful chiefly to the amateur gardener, enabling him, if disposed, to perform many operations without much stooping or tending, which otherwise he would be obliged to submit to; but for real work, the simpler the machine is the better. A good workman with the simplest contrivance would do the work whilst a more mechanical genius was taking off one nozzle and fitting on another; and just on this simple principle, that for getting at the under as well as the upper side of leaves and branches, no joints or bends can ever compare for efficiency with the wondrous backbone and the joints in the limbs of the human operator.

Simplicity cannot be too much studied in all mechanical helps. Take for instance the garden syringe. There is nothing superior to the ball-valved common straight syringe of Read's, and even in that case we care nothing for the two nozzles sent out with it, pierced with holes larger and smaller, the finest sending out the water very slowly but in larger drops than suit our idea of what we term dewing. No, these rose nozzles we generally look upon as pretty ornaments, and useful for those who like to work them, and who care nothing about the time the water takes to escape. The object of our love in the syringe is the single jet nozzle, or rather, as it generally appears, with the seemingly double jet, one for allowing the water to fill the syringe and the other to permit of its leaving it with effect. By placing the thumb on the end of that jet the water, according to the resistance given by the thumb, can be sent out with great force, and in large or

small volume, or it may be forced to leave the syringe as fine as a misty dew, and on either side of the leaf, just according as the thumb and the wrist regulate the supply and the direction. Where is the mechanism that can compare with the joints and bends in a gardener's hand and arm? Do not suppose we say a word against such nice mechanism as we find in garden engines, syringes, and hydropulps, &c.; but we do mean to say that when a man has to carry the water which he uses in syringing, and has to depend on himself without any help, he will find the simplest form of the garden engine or syringe anything but the worst auxiliary. On the same principle we look on all the delivering roses sent out with garden water-engines as of little intrinsic value to the practical workman, as the common jet can be so managed by his thumb as to secure the water being sent out in any force, and almost any quantity, from the regular lashing to that resembling a soft misty dew.

KITCHEN GARDEN.

Planted out Lettuces; sowed more for succession, also a little bit of Endive, Onions for salads, Turnips, Radishes, and Peas and Beans for succession, as the last sowing has been let alone by the pheasants. Have a lot of both to transplant, which must be done without delay. Those turned out formerly are doing well; but, of course, all this increases the labour. Would have formed slight hotbeds for Melons, Cucumbers, &c., but as yet could not get at them. Also, would have placed the foundation of a Mushroom-bed in our open shed if we could, but we hope to get a little straight before long. From previous weeks' notices expected to have got out some forward Celery into beds containing three or four rows each; but part of these beds are not yet emptied of bedding plants, and part are not yet made, nor supplied with rotten dung; but we are easier on this account, as the Celery plants are doing well where they are, and being close together require much less watering than they would do in beds to attain their full size. They will also lift with good balls, and never suffer from the moving, but will require a little shade if the weather should be very sunny. One advantage of turning out large plants is, that they can be well cleaned of all suckers and side growths before planting them out, and much more easily than when fairly planted in the soil. If such suckers are allowed to grow, they rob to a certain extent the main central plant, on which all the attention should be bestowed. Some Celery raised and planted among ashes, as detailed some time ago, is running now; but even the blanched white stalk is as useful for soups as young green Celery. To get that white for the purpose of soups and broths, we frequently leave some rather thickly in our first-prieked-out bed, and earth up with earth and ashes. This is no bad plan for obtaining it very early for the table, or as part in salads; but it is advisable not to have much of it, as it will not compare with what has more room in a bed, or in a single row. Keep prieking out young plants in sandy soil, with rotten dung and leaf mould below; they will come in for late spring Celery. On a drizzling day trenched the Broccoli quarters, as alluded to last week. One word more as respects

Celery.—Many people are afraid to plant out early, owing to the liability to bolt or run, when it ought to be fit for use. We have planted out in May and June strong plants, had good heads fit for use in July, and not had a single run head. We think that some years ago we let out the secret, and it may be summed up in two words: First, never let the plants be stunted from dryness; and, second, dispense with all hit-by-bit earthing-up, and earth up at once from three to four weeks before you want the Celery for use. We have grown Celery of astonishing size by using strong dung and artificial stimulants; but for profitable, nice-flavoured Celery, commend us to a moderate portion of rotten dung and leaf mould well mixed with the natural soil. Very large Celery is expensive to grow, and it is ruinous to keep it long, when fit for the table, as if the rain penetrate to the heart, it cannot get out again, and thus the most valuable part becomes a mass of rotteness. We still like the little Dwarf Incomparable—we can with it obtain so much useful matter in little room. It does not come in so early as some other kinds—that is, unless it is planted much earlier. If it received justice, we believe it might be planted out in the beginning of June, and scarcely show a bolted head until the beginning of the following April.

FRUIT GARDEN.

Some of our trees, especially Plums, that were pictures last season, are showing what birds, encouraged by game, can soon accomplish. Many large branches have not a green twig on them, and all over the tree strong shoots are coming to make

up in growth, and which will require frequent stopping to obtain anything like fruit from them. The trees, we consider, are injured for years. Some beautiful Thorn trees were next to leafless, and are now breaking buds from the old wood, and the birds here, too, did the mischief. Plums, Pears, and Thorns suffered most as respects the wood-buds. Apricots and Peaches out of doors had the fruit-buds pecked wholesale. Apples and Cherries from swelling their buds later have comparatively escaped. When a friend tells us that the sound of a gun must not be heard from the garden premises; that the setting for a rat of a trap that might catch a rabbit or a hare, or worse still, even a pheasant, would be next thing to being sent to Botany Bay; that the thinning even of birds' nests in the dense shrubberies and masses of evergreens that surround the garden would be an unpardonable offence, the immense numbers of such otherwise agreeable visitors being constantly on the increase, encouraged by the food thrown down for game, and of which the little rogues take their full share; and that even as a help he cannot keep a cat or two to frighten, in some measure, the intruders, we have no need for him to tell us how the garden becomes by degrees little better than a game preserve, unless great cost and trouble are incurred for nets, and even then he will not be safe. We have never yet seen a net of the common kind put up that a blackbird, thrush, or sparrow would not find his way safely underneath, and if he only had the sense, when disturbed, to go about it quietly, he could also as easily get out without our seeing or noticing him in time.

Strawberries.—Those out of doors are swelling nicely after the showers, but do not look as if they would give us any ripe fruit for eight days or more. Have thinned them pretty well out of the houses; will soon clear them out of the pits. Those lifted and planted in frames are beginning to change colour, and so is a row that is standing in front of the orchard-house, which we trust will keep us going until we have fruit from the open air. Those who have them in pots in houses must keep a sharp look out, or they may get a dose of red spider they may have cause to remember. In such scorching weather as we have lately had, if ever the soil become dry in a pot, the red spider will soon visit the leaves, and he will not stay there. If ever the plants are in pots, if we could, we would always have them in pits after May, with the pots set in from 1 to 2 or 3 inches of soil, according as the time dated from the 1st of May to the beginning of June, as then, with the command of artificial heat when necessary, and the cool moisture at bottom, it would be easier to keep red spider at bay than when the pots were set on a shelf either in saucers, or without them on turf or moss. We have some standing on moss and turf now, the moss and turf being a complete mass of rootlets. When the pots stand on earth it should be so porous and open that the water may pass through it. We have removed nearly all the Strawberries from the Peach-house, and not too soon. The first plant affected with the red spider was one where the drainage-hole in the bottom of the pot was clogged up. Stagnant moisture is as effectual for causing a sickly habit as excessive temporary dryness.

Peach-house.—Unless in cold nights give no fire now, and plenty of air, as the fruit is coming fast enough, and fine, though a heavy crop. Gave a good watering with drainings from the dunghill, which will help to keep the house cooler and swell off the later fruit. Gave also a good watering to the orchard-house from similar drainings, as the rains had helped to fill the manure-water tank. We prefer this for in-door watering, and would confine sewage-water, if we could, always to open-air watering. We are fully convinced that most of our cottage-gardener friends would vastly increase the produce of their gardens if all the slops and washings from the house were carefully kept, if in no better receptacle, in a good clay pond or tank, covered over, and then applied the liquid to all the rougher vegetables when in a growing state, and without touching any of the leaves.

Vines, Figs, Melons, &c.; much the same as in previous weeks.

ORNAMENTAL DEPARTMENT.

Whilst attending to potting and packing Orchids, dividing some Ferns, &c., in drizzly days, the chief work has been, as the weather would permit, going on with planting the flower garden, and getting the lawn and walks in order. We never were so late in planting out, and we do not know if we have any reason to regret it. Most of the plants had been turned out and were growing in temporary beds, and were lifted with a trowel or little fork, and carried in boxes at once to the appropriate place, and after a day or so hardly one showed signs of

distress even in a bright day. There is this advantage, besides many others as respects watering, &c., in the case of such plants planted out in a temporary bed, and lifted and planted—that the fibres go at once into the fresh soil of the well aired bed. One disadvantage is, that sometimes if the ball formed is large it is apt to break and take the fibres with it. We would sooner have all the nice fibres without a ball, than have the fibres lost in the above way. For such plants, after being once watered at the roots, a skiff over the foliage, as alluded to in the beginning of this article, we generally find soon makes them all right. We had occasion to move a few Geraniums that had been planted three days, and found that the fibres had run fully an inch into the new soil. After they do that they will pretty well look after themselves, and will bloom all the better the less watering and rains they have—that is, as a general rule; for once we had Scarlet Geraniums that began to wither up in the dry summer, the drought having got down to the extremity of the roots, but they did not do so until long after Calceolarias and Verbenas, also left to themselves, perished. As a general rule, when once Scarlet Geraniums take hold of the ground, the less moisture they have the better they will do.—R. F.

COVENT GARDEN MARKET.—JUNE 16.

LITTLE or no alteration in our last week's quotations shows the condition of our market, supply and demand being about balanced. The present retarding weather favours the sale of foreign fruit, among which some tons of Strawberries have been disposed of during the week, selling at about 1d. per lb., chiefly among the street vendors.

TO CORRESPONDENTS.

BOOK ON FERNS (*Pour passer le temps*).—If you mean works on Ferns indigenous to our islands, "The British Ferns." It can be had free by post from our office if you enclose 3s. 6d. in postage stamps with your direction. We shall be glad to see your notes on "Microscopic Researches" as soon as it is convenient to yourself.

GAUBS IN ROSE BUDS (*Charles Hamilton*).—The dark-coloured fat-tish grub which gnaws into the buds of Roses is the larva of the pretty Tortrix (*Argyrotoza Bergnauniana*). The more slender green one with whitish lateral stripes is that of one of the Geometridæ (*G. Yvauria*). Careful hand-picking of the infested buds is at present the only remedy. When the moths appear they might be trapped by bird-timed twigs stuck about the plants.—W.

OKRA PLANT CULTURE.—"J. P. G." would feel obliged by any of your readers who have tried the cultivation of the Okra plant, saying whether they have succeeded in producing pods without stove heat, and how treated. The Okra plant (*Abelmoschus esculentus*) is a native of the West Indies, where it is cultivated especially for thickening soups, as it is very mucilaginous.

COLD GREENHOUSE PLANTS (*Amateur*).—You are quite right as to the plants for your cool greenhouse. You could not have much from it in winter for parlour decoration, but you could bring on bulbs in it, also Stocks and Wallflowers. Hardy annuals would stand in it in winter and bloom early in spring, and Balsams and many other things could be had in great perfection.

DESPONDICUM VORILE (P. D.).—The pseudo-bulbs or stems which are the growth of this year do not die in the next, but lose the leaves, and flower in that or the following year; but under cool treatment, or when grown in ainery, they will not flower until the commencement of the growth of the third season. When the stems have ceased to grow and have become thick and plump, the plant should be put to rest by withholding water and keeping the atmosphere drier. In spring the old leafless stems will exhibit a number of small knots or excrescences, and when these begin to swell a moister atmosphere may be afforded; but if such do not appear, then the new growths will be produced from the base of the last year's stems and upon them, and this is the indication by which you may know when to start the plants. The flower-buds are formed in summer, and the flowers appear about the time the new growths are being made; sometimes before, but generally with the new growth, according to the temperature. It usually flowers in April and May. It does well with us in an earlyinery, but not in a cool one.

VINES INFESTED WITH RED SPIDER (S. P.).—The leaf sent is infested with red spider. You say you have not syringed the Vines. The red spider delights in a dry atmosphere, but cannot endure moisture. If the syringe is not now used with force, it will be in vain looking for a crop, as the leaves will be all gone before the fruit is ripe. If you have plenty of clear rain water syringe the Vines with it every evening, from 5 to 6 P.M., directing the force of the water against the under sides of the leaves, so as to wash off the insects. Give air early in the morning, when the sun is powerful, increasing it with the increase of heat, and always by the time the sun shines powerfully upon the house whilst the leaves are wet, but never fear to shut up after syringing in the evening. Continue the syringing until the Grapes change colour, then leave it off. In addition to syringing, sprinkle the paths, floor, &c., with water in the morning, and continue to do this until the Grapes are far advanced in colouring. If the water at command is not soft, or not clear, then (and even if it be soft and clear) dissolve 4 ozs. of softsoap in two gallons of water, and add sufficient flowers of sulphur to form a thin paint. With this wash any well on which the sun shines powerfully, also coat the flue or hot-water pipes now, making the flue hot, but not hotter than the hand can bear for a short time—say a minute. Do this in the evening after the house is closed, and when the heating surface is covered with the sulphur gently syringe the same from end to end, until the house is filled with vapour. Syringe forcibly in the morning, giving air before the sun shines very powerfully upon the leaves. Repeat this when the syringing is discontinued. Red spider promises to be unusually abundant this year, both in houses and out of doors, and to prevent its attacks we recommend frequent syringing with water.

AZALEA CUTTINGS (A Young Gardener).—Take cuttings 3 or 4 inches in length from the growing points, when the wood is about half ripe. Cut them transversely below a joint, and remove the leaves from the lower two-thirds of the cutting. Prepare a pot by filling it to two-thirds of its depth with crocks, on these place a thin layer of moss, and then such a quantity of sandy peat, that when the cuttings are inserted their base will be the least possible distance above it. Fill the pot to the rim with silver sand, and then insert the cuttings around the sides, putting them in up to the leaves. Give a gentle watering, and plunge in moss, sawdust, sifted tan, or some such material, over a mild bottom heat of 75°. A close frame is best, and the cuttings are better inserted singly in pots. If there is not the convenience of a close frame the cutting-pot may be placed in one of larger size, and the interval between the pots filled to within an inch of the rim with broken pots, and the remaining space with silver sand. The rims of both pots should be on the same level, and a bell-glass put on must rest on the sand between the pots. In this case the cuttings may be placed in a shady part of a house having a heat of from 65° to 75°, or 80°. In either case keep the soil just moist, and the cuttings close and shaded from bright sun; when they begin to grow admit air by tilting the bell-glass or light, and gradually harden off. They will be fit to pot off in six weeks.

CYCLAMENS POTTING (Idem).—In potting, the corm or bulb should be covered with soil if it be that of *C. persicum*, and those of *C. coum* and similar kinds may be covered an inch above the crown.

PLANTS LIKELY TO TAKE PRIZES.—“*C. H.*” encloses two sets of stove and greenhouse plants, including Orchidaceæ, and asks which list ought to have the first prize, supposing the plants in each set to be equally well grown. This is one of the questions which it is next to impossible to answer without seeing the specimens; but in a collection of nine stove and greenhouse plants, where the collections in other respects were equal, we would be inclined to prefer the collection containing *Cattleya Mossie superba*, *Lycaste Deppel*, *Azalea Iveryana*, *A. Beauty of Europe*, *A. Van Houttei*, *Epacris miniata splendens*, *Boronia tetrandra*, *Eriostemon nerifolium*, and *Tetratheca hirsuta*.

FLOWER-BEDS (Ronnoc).—Your previous planting would do very well, and it would be well to alter the planting of the beds so as to insure a succession of cropping. Were we to tell you how it would be best to plant on a fresh plan, we should break our rule not to plant any garden but merely to criticise and advise on the proposed plan sent. Were we to do so, we should be inundated with plans, and then do little or no good in attempting to plant them. For instance, what would be the use of our stating what would suit your beds best if you did not have, or could not obtain, the plants? Some of our friends manage us nicely in this way: they tell us what they intend planting, and add what other plants they have and can use, and this opens up a way of doing the best with what is at hand. Many of the best gardeners plant not exactly as they like best, but make the most of the plants that they have. Few employers will let their gardeners buy dozens and hundreds of this and that at planting time.

COCOA-NUT FIBRE REFUSE—STRAWBERRIES FOR HEAVY SOIL (Amateur).—We consider the refuse the best of manures for the Strawberry, and very desirable to apply to heavy ground for Strawberries and all descriptions of vegetables. The kinds of Strawberries we grow and can recommend are for early use: Black Prince, Eclipse, and Marguerite; and, to keep up a succession, Keen's Seedling, La Constante, Wonderful, British Queen, Frogmore Late Pine, and Elton. On very heavy soil La Constante runs badly and dies off in winter, but on light and medium soils it does well, and is one of the very best.

RAISING PLANTS FOR BEDDING-OUT (E. D. R.).—We propose to publish some notes on the subject shortly.

GREEN FLY ON ROSE TREES (L. R. C.).—Syringe the heads of the trees forcibly with water in which softsoap has been dissolved at the rate of 1 oz. to the gallon of water. Continue to do this every evening, wet or dry, for a week, and, on the aphids disappearing, syringe with clear soft water until the blooms open; but, if the aphids do not disappear, syringe the heads in the evening of a dry day with tobacco water, made by adding five gallons of soft water to every gallon of the tobacco liquor sold by the tobacco manufacturers, wetting the leaves and shoots thoroughly in every part. On the following morning syringe the trees with clear water. If this should not clear off the aphids, repeat the application next night but one. If tobacco liquor cannot be had from the manufacturer, take the strongest shag tobacco, and over 2 ozs. of it pour one gallon of boiling water, cover with a cloth, let the whole stand until cool, then strain, and apply the liquor to the trees by means of a fine-rosed watering-pot or syringe. The same liquid will answer for the destruction of aphid on all kinds of trees as the Peach, Cherry, Plum, &c.

LIQUID MANURE FOR ROSES AND POT PLANTS (Idem).—There is no safer manure for Roses than Peruvian guano, 2 ozs. dissolved in a gallon of water; and of this strength it may be applied twice a week in dry, and once a week in moist, weather during the growing season. For plants in pots, such as Fuchsias, Geraniums, and the majority of softwooded plants, the liquid should not be so strong; 1 oz. to the gallon of water is sufficient, and it should be applied to them only during their season of growth. When the pots become filled with roots it may be given at every alternate watering.

PLANTS FOR A POND (D. W.).—We know of no plants that will do in a pond so deep as 6 feet. If you were to have it filled up so as to make it from 2 to 3 feet deep in the deepest part, you might there plant *Nymphaea alba*, *Nuphar lutea*, *Villarsia nymphoides*; and nearer the sides, in from 6 inches to a foot of water, *Ranunculus aquatilis*, *Myriophyllum spicatum*, *Iris pseud-acorus variegatus*, *Hydrocharis morsus-ranae*, *Butomus umbellatus*, *Aponogeton distachyon*, *Acorus calamus*, *Alisma natans*, *Chara flexilis*, *Caltha palustris flore pleno*, *Hottonia palustris*, *Lysimachia thyriflora*, *Potamogeton densum*, *Stratiotes aloides*, *Sagittaria obtusa*, and *Carex acuta*.

CUCUMBER ROOTS DISEASED (A Two-years Subscriber).—We think the excrescences on the roots, though ever present on aged roots, are more plentiful than is generally the case owing to the large amount of vegetable matter in the soil used. The only remedy is to use a more sweet and less rich soil. To the leaf mould which you use one-half good medium-textured loam should be added. A deficient root-action and imperfect growth are the conditions under which the roots become covered with excrescences as yours are, and that we find induced by a soil too rich in vegetable matter, and not kept sufficiently moist to ensure free growth.

STRIKING PANSY CUTTINGS (Agnes).—The cuttings will grow if inserted in a border shaded from 8 A.M. to 4 P.M., the soil being kept moist. They will also root if they be inserted in a free sandy soil in an open situation, the soil being kept moist, and the cuttings sprinkled overhead morning and evening with water from the rose of a watering-pot. Shade them from bright sun with a mat over hoops.

GERANIUMS LEGGY (Idem).—The cause of this is neglecting to pinch out the points of the shoots, and that should be done in the first instance at the fourth leaf, and this treatment to be continued to the side shoots up to the end of April. Your plants will thus be compact when turned out, and they will be in fine bloom by the early part of July; but if you turn out leggy plants the best plan is to lay them down, and the bare shoots or stems throw out fresh shoots, which grow close and stiff. Your tall plants will, we think, be now pushing from near the bottom. We would not stop the plants now, nor pinch at all during summer, as they will push low enough to hide their bareness.

CUCUMBERS DYING OFF AT THE ENDS (J. B. K.).—It is mainly owing to a deficiency of bottom heat, accompanied by a cold, damp atmosphere. We think that you water far too often; once a day is very often. Water is rarely required oftener than every other day, but it should be given when the soil becomes dry; syringing twice a day will lessen the necessity of frequent watering. The soil should be kept moist but not sodden. The syringing is all right, only you must do it by 4 P.M., and then shut up the house; and if the weather be cold, and you have no fire, it would suffice to sprinkle the paths, floors, &c., twice a day instead of syringing the foliage. Your cropping the plants heavily will make the fruit small at the ends, and they will not swell well. Liquid manure may be given at every alternate watering. Avoid a saturated soil, and husband the sun heat by closing the house early in the afternoon. Syringe only during bright weather.

VINE LEAVES DISCOLOURED (Wansbeck).—The leaf sent is mildewed. Dust immediately the leaves so affected with flowers of sulphur. There are also traces of red spider. In three days after applying the sulphur, syringe the Vines with clear soft water, directing the force of the water against the under sides of the leaves, and repeat this every evening until the Grapes change colour. Give air in the morning before the sun shines powerfully upon the leaves or house.

ARTICHOKEs (Charles Elliot).—The “runaway” flower-buds at the top of the shoots or stalks are, when they attain the size of a teacup, to be cut, boiled, and eaten. They are the eatable portion of Artichokes. They will not form anything edible at the bottom in the shape of tubers unless they are Jerusalem Artichokes, which we apprehend they are not, but Globe Artichokes. The first have a leaf like that of a Sunflower, and the second one more resembling a Bur Thistle, but glaucous. Look after the heads, and never mind the bottoms, only cover them as you did last winter, and fork the manure in in spring.

CALCEOLARIAS (Wm. H. Teignmouth).—Your Calceolarias are not equal to many we have seen there, there are three or four good flowers, but not distinct from others. The generality of your seedlings lack form; a good Calceolaria must always possess the first and most important requisite, a circular outline.

SEEDLING PELARGONIUMS (A Gardener).—Your two seedling Pelargoniums are very delicate and pretty, and decidedly useful for bouquets and decorative purposes. They are not florists' flowers which could be grown for exhibition. *B.* seems the best flower, and the best trusser. If of good habit, cultivate both; they will be excellent for general use.

NAMES OF PLANTS (T. B. D.).—The tree in Lincolnshire from which you cut the flower you enclosed is *Faulownia imperialis*. (Caroline).—

Fedia olitoria. (*G. B. B.*).—*Claytonia perforiata.* (*Lachenalia*).—1, *Halesia tetraptera*; 2, *Lonicera tatarica*; 3, *Pulmonaria officinalis*; 4, *Ajuga reptans*; 6, *Geranium sanguineum.* (*W. Taylor*).—*Pyrus aria.* (*W. L.*)—

1, *Halesia diptera*; 2, *Viburnum cotinifolium*; 3, *Crataegus subfucra.* (*W. H.*).—1, *Viburnum opulus*; 2, *Philadelphus coronarius*; 3, *Crataegus sanguinea.* (*R. T. Wheeler*).—*Malvastrum capense.*

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 16th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FIVE HOURS AT SALISBURY.

THURSDAY morning, June 7th, found me most unexpectedly on my way to Salisbury. I went thither by excursion train, the first I ever stepped into. I imagined all such must be crowded, noisy, disagreeable modes of conveyance, uncertain as to time of starting, and more uncertain as to time of arrival; but not so this one proved: all was quiet and orderly—no hurry, no confusion, and we started and arrived to a minute. Still, ever since I read Punch's epitaph on an old railway engine I have the more shunned excursion trains.

"Grown old and rusted,
His boiler busted,
He smashed the excursion train."

I kept repeating. No, I did not want to repeat it; but that line would ring in my ear yesterday,—

"He smashed the excursion train."

But our engine was better-behaved—he did not smash the excursion train.

On and on towards Salisbury. Grass crops light everywhere. Now at Wilton, that little suburb of Salisbury—a mere village; its entire population 1930, and of that number upwards of 1000 females. Connected with Wilton are the name and deeds of that truly great statesman Sidney Herbert; its wonderful Byzantine church (I don't like it for an English church, though), seems now dedicated to his memory. Sidney Herbert—the one whom Lord Palmerston looked to as his successor—high-bred, courteous, manly, kindly, a fit successor to Palmerston; but it was not to be!

Here we are at Salisbury, omnibuses charging double of course. A mile to the show-yard. No change given there, for it is the shilling day, and no time to lose. I am within the show-yard, high, dry, and healthy; no fear of wet, for did I not leave my glass rising at Hilltop Rectory? My glass is my priest—a kind of better Pope, for I know it is infallible. Catalogue in hand, I now prepare to explore the Show. I open the map, always the best plan, and by studying it become master of the situation of every tent.

The cattle are, poor things, "conspicuous by their absence." "The machines in motion" are most conspicuous by their presence. Never did I see such a long row of puffing steam-engines—they made one hot to look at them. Implements vastly abundant. Said a farmer, "The expense of showing them comes out of our pockets;" but that was not the best thing I heard from an agricultural mouth. Sitting near the band, close to a good old-fashioned-looking farmer, wide in waistcoat and double in chin, he looked up at the motto of the Bath and West of England Society floating above us on a flag—"Work and Learn." "Aye," said he, "work and learn is it? Work at whoam, and then come and learn here, and then go whoam and work better, that's it." And a good explanation, too, of the use of an agricultural meeting. Implements! implements! I have no time for you. Picture-gallery—well, "very pretty." That's a safe criticism; it used to be that of Samuel Rogers. But why will water-colour artists make their ladies' faces so high-coloured? for rouge is not much used now-a-days. "Art-manufacture" tent, full of the fruits of man's ingenuity. Now I am at the "Horticulture" tent. What a blaze of Geraniums and Azaleas! but the colour toned

down by the graceful Ferns. This is right; too much colour, or colour only, makes the eye ache. Nature has plenty of green always, even in the Tropics. Beautiful flowers! Charming Roses! I see my old friends Cloth of Gold and Lamarque among them.

Next come the dogs—a first attempt at a show, and a creditable one; a late thought, and so not a large show. The first-prize greyhound was greatly admired, and Wilts is a first-rate coursing county. Many of our readers are doubtless familiar through the engraving with Landseer's "Uncle Tom and His Wife,"—I think I am right in the title—two bulldogs, wonderful as dogs, but not less wonderful in their likeness to niggers. Now, there was one bulldog at Salisbury, only one, and it was black, and its likeness to a negro was wonderful. It wanted but a queer hat or red handkerchief to be complete, so nigger-like yet canine, canine yet nigger-like. Horses next, but not a very satisfactory lot; but there were "darling ponies," as the ladies called them.

Well, there is the poultry tent at last, crowned by some dozen flags. Other tents have but one flag, but the poultry tent many, which is quite right—a goodly long tent, 300 feet by 40. A tall policeman graciously, almost gracefully, waves his hand, and bids me enter to the left, which is quite correct, for there before me stands Pen 1 of Class I.—viz., Spanish. Concerning the poultry generally, which my county paper most properly said "was one of the most attractive features of the meeting," there were upwards of three hundred entries, being about ninety more than last year. The Spanish class was a very good one. Lady Holmesdale was first with birds which cannot be shown again for some time, as they had nearly plucked themselves or plucked each other bare. Mr. Jones, of Bristol, was second. Wiltshire was well represented in Mr. A. Heath's four pens, one of which was highly commended. Class 2, Dorkings, was the largest class of all. Lady Holmesdale was first and second, her Rose-combed being the latter. Only a few White Dorkings were shown, but the first-prize pen was very good. Of Cochins, Cinnamon and Buff, there was but a small entry—very small; and the prizes went to Manchester and Birmingham, save the third to Miss Milward. Other Cochins were not numerous. The Brahms were very good indeed, the Dark on the whole being the best. In Game, as usual, the Black-breasted and other Reds exceeded the other colours in number. It is not a good time of the year for Game. The prize Black Game looked, however, wonderfully well. The Hamburgs were all good. As a proof that they are not yet very general in the south and west of England I heard many humble folks (twas the shilling day), pause, and ask, and blunder about their names. Mr. Beldon beat Lady Holmesdale in Silver-pencilled, which was something to be able to do. Out of all the Hamburgs only one pen belonged to Wiltshire: this should not be. Then I mourned over there being but two pens of Black Polish. Good indeed they were, but why not more? Golden Polands but three pens, Silver but two! Again I ask some one to go vigorously into this variety of fowl. Malays, six pens—well, they may be handsome. Minorcas, Crève Cœur, and Any other distinct variety—I am surprised that so many appeared, but they make up a show. Among the single cocks were many good birds, the Cochins being least excellent. But one pen of Golden-laced Sebrights good—very good, but only one; Silver-laced four. But oh! my little Black friends, you are looking up—six pens of you to one White and nine Game! Ducks abundant, and many from

Wiltshire, Geese, Turkeys, Guinea Fowls, a goodly number. Then these supreme pets, Pigeons. Just as I was going to look at them my feelings were greatly hurt by my next neighbour—from Beotia I should think—saying to his friend, "There, there! don't go along there, there's only Pigeons." Mr. Ord, Mr. Else, Mr. Fulton, Mr. Yardley, Mr. Heath, and Mr. Pigeon (by name and nature a fancier), sent good birds. The Show was remarkable for the number of Magpies exhibited, there being more of that variety than any other, except Carriers, which exceeded but by one. Among the Dragons I greatly admired a pair of White—they were elegance itself.

The poultry tent was all that could be wished, large, airy; but I regretted to see so many empty pens. Query, Was it the fault of those foes to poultry, foes by expense and delay, the railway companies? I think if to each railway director, wearing nickerbockers for the occasion, a few nice fierce Game cocks were permitted to set to, in an empty room, with no stick or any weapon allowed, it would be a proper punishment. How charming to see a gouty director hop and kick, kick and hop!

In conclusion I have a suggestion to make. The barley given is, of course, very heating at this time of year, and more especially to birds in confinement in a hot and crowded tent. This leads them to peck each other. I noticed a hen of Lady Holmesdale's second-prize Dorkings literally picking to pieces the rose comb of the cock—eating it, or getting the blood. This, I think, might be obviated by giving at the summer shows stiffly mixed oatmeal instead of barley. Three times I went among the pretty birds, and as the day advanced many were deterred entering from the great crowd; and, indeed, it was struggling back-bruising work, for poultry are popular with all. Many who do not keep them, nor even know their names, make a point of visiting their tent.

Four o'clock the show-yard became fuller than ever, and I take my exit. Often had I turned to look at the graceful spire of the beautiful cathedral, which silently in its beauty looked down upon the crowds. I now pay it a brief visit—see the wonderful chapter-house, now restored at the cost of £8000; very beautiful it is. In the centre of the octagonal building stands a pillar. High is the roof, and it seems to branch from the pillar as from a stem. The idea is that of a palm tree, and in truth it looks a petrified palm with its trunk chiselled. Welcome cool cloisters! Welcome a sit in the mighty nave, now happily used for service after centuries of disuse! Then shortly I go out to the cathedral close, so old world-like and quiet; a peep next at the "poultry cross," suitable after a poultry show; and one reverential look at the statue of Sidney Herbert in front of the Town Hall—a good likeness, and the figure very like—on the polished black of granite upon which it stands simply the two words "Sidney Herbert;" then on to the station, where punctual to a minute was my excursion train.—WILTSHIRE RECTOR.

PROFIT FROM DUCKS.

The following account of an experiment in feeding Ducks may interest some of your readers. Ten Ducks were hatched on April 11th, and eight on April 16th. Of the last brood one died, two were stolen by a dog, and one was accidentally injured. Of the remaining fourteen, one was killed when eight weeks old, and weighed 4 lbs.

Estimating the value of the ten at 3s. each, and four at 2s. 6d., we have the following result:—

COST.		£	s.	d.	Estimated value		£	s.	d.
Eggs	0	3	0	Estimated value	2	0	0
Toppings	0	3	0	Deduct cost	0	12	1 1/2
Food for two hens	..	0	1	0					
Loss of hens' time	..	0	1	0					
Oatmeal	0	0	3					
Indian corn meal	..	0	2	0					
Grains (beet)	0	1	10 1/2					
		£0 12 1 1/2			Profit	£1 7 10 1/2			

The Ducks were the common farmyard breed. They were kept shut up, but for the last fortnight have been allowed to go into the water for one hour a-day before their midday meal. The only addition to the food here mentioned has been the refuse of the house and garden.—B. A.

BLACK BANTAMS AT BIRMINGHAM EXHIBITION.—Mr. E. Cambridge, 2, Brunswick Terrace, Stoke Croft Road, Bristol, wishes to have the names of exhibitors who would subscribe towards extra prizes.

HANTS AND BERKS AGRICULTURAL SOCIETY'S POULTRY SHOW.

This Society is growing wiser as its years increase, and it is not above following a good example. It sees how the Bath and West of England and the Northamptonshire Shows have increased and prospered by moving from place to place. It finds also the benefit of enlisting various towns as its friends and supporters. Its Show was in 1864 at Basingstoke; in 1865 at Winchester; and 1866 at Reading. Its advocates already speak of having a two instead of one day's show. This year will long be memorable as a trying one for agricultural meetings. It is a large gap that is made in the show-yard, when the rows that are devoted to horned cattle are empty; and as the attendance must be considered one that is made up of visitors to all the different classes, it may safely be said that if the number of admittances is a satisfactory one now, when happier days dawn upon us and the underpest has become a thing of the past, when the addition is made of all that come to see and are interested in horned cattle, it may be estimated that a large success will be achieved. We are enabled by the courtesy of Mr. Downes, the excellent and able Secretary, to say now that the prizes will be increased in number next year, and new classes will be added to the present list.

Many of the birds that had been to Salisbury came here, and the condition in which they were shown reflected great credit on the managers of that great Show. We shall review the classes as they occur in the list; and, as the prizes are printed, we shall touch only on those points that seem to demand notice.

Dorkings were very strong. Capt. Lane's pen was a remarkable one, and if well cared for and judiciously managed they are destined to many more triumphs where the numbers may be much larger. Miss Milward's and Mr. Parlett's were very good; but the first prize was easily won. There were fourteen pens, and twelve of them excellent. There was one pen of Rose-combs, but we saw with regret that they were almost the smallest in the class, and we heard many remarks, from which we differed, that the Rose-combed were always smaller; and some were disposed to deny them rank as Dorkings at all. We are at a loss to account for the next class. Three prizes were offered for *Cochins*—£2, £1, and 15s. They produced two pens, both good; but the entries astonished every one. The merits of this breed deserve better than this, and when poultry assumes its proper importance we shall have no such classes as this. *The Game* were excellent; the Brown Reds of Mr. Cruwys, Mr. Dupe's Black Reds, and Mr. Cruwys' Pales left nothing to desire. *Polands* held their own, Mrs. Pettat taking second to Mr. T. P. Edwards. *Hamburghs* will next year require four instead of two classes. We had to notice the superiority of the Golden over the Silver-pencilled. Mr. Pittis, of the Isle of Wight, took both prizes. It is curious that the old Golden retain the correct and distinct pencilling, while the Silver become patched and mossy. Mr. Wood, of Kendal, showed an excellent pen of Golden-spangles, beating very good birds belonging to Mrs. Pettat. The classes for Light and Dark *Brahmas* would have done credit to any show. Mr. Pares took both prizes in the first class deservedly. The competition in the second was much closer, not so much for the first prize, which went to Capt. Lane, as for the second, which was awarded to Mr. Pickles, of Todmorden. Messrs. Johnson and Sherman deserve mention. It is intended next year to have *Bantam* classes. This will diminish the various class, which had Game and Selbright Bantams, Malays, Andalusians, Black Hamburghs. Mr. J. Hutton showed very good *Malays*, and Mrs. Pettat very good *Bantams*.

Mrs. Seamons took all the *Duck* prizes. There were but few *Turkeys*. Mr. Lang's were very large, and Capt. Warren's white ones in beautiful condition.

The attendance was very large, and the Meeting a success.

DORKING.—First, Capt. H. B. Lane, Bracknell. Second, Miss J. Milward, Newton St. Loe, Bristol. Third, F. Parlett, Chelmsford. Highly Commended, Capt. H. B. Lane. Commended, O. E. Cresswell, Hanworth.

COCHIN.—First, Miss Milward, Newton St. Loe. Second, Mrs. Seamons, Hartwell, Aylesbury.

GAME.—First, S. Dupe, Evercreech, Bath. Second and Third, Rev. G. S. Cruwys, Cruwys Murchard. Highly Commended, S. Dupe.

POLAND.—First, T. P. Edwards, Lyndhurst. Second, Mrs. Pettat, Ashe. Highly Commended, J. Hinton, Hinton, Bath; Mrs. Pettat.

SPANISH.—First, A. Heath, Calne. Second, Rev. J. de L. Simmonds, Chilcomb Rectory.

HAMBURGH (Silver or Gold-pencilled).—First and Second, F. Pittis, Newport, Isle of Wight. Highly Commended, A. K. Wood, Burnside, Kendal.

HAMBURGH (Silver or Gold-spangled).—First, A. K. Wood, Burnside, Kendal. Second, Mrs. Pettat. Highly Commended, R. Harman, Cowley, Oxford.

BRAHMA POOTRA (Light).—First and Second, J. Pares. Highly Commended, Miss Hayes, Arborfield Rectory.

BRAHMA POOTRA (Dark).—First, Capt. H. B. Lane, Bracknell. Second, J. H. Pickles, Bridgeroad, Todmorden. Highly Commended, G. Johnson, Farham; E. Sherman, Chelmsford. Commended, C. Cork, Shoreham.

ANY VARIETY.—First, Mrs. Pettat, Ashe (Silver-laced Bantam). Second, J. Hinton, Hinton, Bath (Malays). Third, Mrs. Pettat, Ashe (Game Bantams). Highly Commended, F. G. Phillips, Chippenham (Black Hamburgh); C. Cole, Fareham.

DUCKS.—First and Second, Mrs. M. Seamons, Aylesbury.

TURKEYS.—First, S. Lang, jun., Bristol. Second, Capt. R. P. Warren, Worthing.

GESE.—Prize, Mrs. M. Seamons, Aylesbury.

RABBITS.—*Longest Ears*.—Prize, E. E. M. Roids, Whitchurch. *Salop. Self-colour*.—Prize, G. Hill, Winchester. *Foreign*.—Prize, Mrs. M.

Seamons, Aylesbury. For *Variety* (to include all points).—Prize, G. Hill. Highly Commended, P. Warren, Southampton.

Mr. Baily, Mount Street, Grosvenor Square, was the Judge.

ARTIFICIAL SWARMS—STRENGTHENING STOCKS.

I AM looking anxiously for another "pure queen" which "A DEVONSHIRE BEE-KEEPER" so kindly promised in page 388, in order to supply my loss. At the risk of being tedious to your readers allow me to say that hitherto I have been quite successful in forming five artificial swarms from one stock this season. I have actually seen the queen in each hive, except No. 4, but I saw two sealed ones there a few days ago. No. 1, formed on the 3rd of May, contained eggs and rather large grubs on the 2nd of June, so that I presume the queen must have laid about the 29th of May—i. e., on the thirtieth day from the formation of nucleus. At twenty minutes before twelve to-day (13th of June), I saw the queen leave No. 3, but she returned almost immediately. I was looking for her return most intently when what I supposed to be a drone flew between me and the hive; it was the queen, which alighted immediately

afterwards. I mention this fact because I do not remember hearing the sound of a queen's flight before. Had I not seen what I have just related I should have been satisfied that the sound proceeded from a drone in search of a companion.

I cannot, of course, tell what sort of season other counties are promising for bees this year, but I fear we shall not have a good one. Up to the 7th of June I did not hear of more than one cast or swarm. A considerable portion of the month of May was too dry, and now the weather continues gloomy and rather cold, with frequent showers. When my small swarm arrives it is my intention to transfer the bees to a Woodbury hive in the course of a day or two, and gradually to strengthen them by the addition of ripe brood frames from other hives. Will this plan not answer as well as the plan of driving?—E. B., CLERICUS, Cumberland.

[Your pure Italian queen at the head of a small swarm will probably reach you about the same time as this Number of "our Journal." Your plan of strengthening the small colony by the gradual and judicious addition of ripe brood-combs is by far the best, and would have been suggested in preference to driving had I known that your hives afforded the necessary facilities.—A DEVONSHIRE BEE-KEEPER.]

MY APIARY.—No. 1.

HOW I CAME TO BUILD IT, AND HOW I WORK IT.

"Imprimis, sedes apibus statioque petenda."—VIRGIL.

(In the first place, stands and a station for the bees are to be sought.)

WHAT would appear to have been a matter of primary importance with bee-keepers in the time of Virgil has remained the same ever since. "Where shall I place my bees, and what sort of shelter must I provide for them?" is the first inquiry made by every tyro in the art; and the chances are, that although at his first start he was content with the low, rough block of wood (which time out of mind had been used by the old cottagers in the village) as a settle, and the jaunty straw hackle, or red milk-pan, as a covering for his bees, yet, if he has persevered in the work, and come, as most bee-keepers do come, to love his bees, and feel anxious to provide in the best way for their accommodation, he will, if he have the means at command, have gradually advanced from this stage of the art until his garden is furnished with some such useful and ornamental building as that which is represented by the woodcut accompanying these remarks.

My first stock of bees (in a cottage hive of course) was purchased about the year 1850, and placed in my garden on a block of wood, which, as there was no bottom board to the hive, seemed to form a necessary part of it. From this block it was speedily removed to a neat oak stand, such as is recommended in the useful works of Messrs. Taylor and Payne, and the swarms which issued from it were placed in Payne's flat-topped straw hives fitted with appropriate supers; then followed a trial of Nutt's collateral-boxes, after these Payne's square straw hive with bars; Goding's Grecian hive with bars, Payne's and Glennie's bar-boxes, were used in succession; next after these Teget-

meier's frame hive; and, last of all, J. I. Langstroth's moveable comb hive, which I have adapted to my own requirements, and which is the only one now used in my apiary.

As with the bee-hive so with the bee-house. There has been the same gradual progress here. My first was something after the fashion of a kitchen cupboard, fitted first for two sets of Nutt's collateral, and, when these were given up, for four Grecian hives. The next was a house for myself as well as the

bees, being a common garden summer-house, which (by closing the opening with folding doors, and turning the back round to the south) furnished tolerable accommodation to both parties, and served the purpose very well for some years. But this, in its turn, was discarded and recon-verted to its original use, for the little Swiss cottage which is now used as my apiary, and at the same time forms a pleasing ornament to my flower garden. The design was borrowed from a brother clergyman, but the workmanship was my own, and as I do not consider myself a skilled hand, I may safely say it is not difficult of

construction. Since its erection about eight years ago, it has been much admired by my friends, and having during that time found it most convenient to myself for the purposes of observation and manipulation, and suitable to the requirements of my little favourites, as the results testify, I am glad to have the opportunity of recommending it to my apian friends.

So much for the building of my apiary; in my next I will furnish dimensions, &c., when I describe, "How I work it?"—SIMPSON, BIRMINGHAM.

PREVENTING DRONE-BREEDING.

In managing bees on the supering system drone-breeding is not profitable, and unless specially required may be dispensed with altogether. Now, I find that unless all the frames in a Woodbury box are furnished with comb before a swarm is put into it a large proportion of the empty space will be quickly filled with drone-comb; this I have in several instances cut out, but the bees obstinately refuse to take the hint, and will persist in providing accommodation for those honey-consuming idlers. I should be glad to know if there is any plan for inducing the bees to build worker instead of drone-comb? or if not, which is the better plan—to keep cutting out this troublesome comb, or allow the bees to have their own way? In other words, will the difference between the honey consumed by the drones in the one case, and the waste of time and material in the other, be in my favour or otherwise? and also, will the entire suppression of the drones have the effect of more effectually preventing swarming?—G. L.

[The use of the German artificial combs, or impressed wax sheets, will generally induce bees to build worker-combs. It is, however, scarcely possible, and even if possible we very much doubt if it would be found advisable, so to thwart Nature as to attempt the entire suppression of the male element in a hive, since, if no other evils result therefrom, an undue proportion of drone-comb is likely to be fabricated in the super, and there tenanted by the queen. We nevertheless often find it advisable to impose some limits to drone production; but when we remove superfluous drone-combs from a stock hive we do not trust the bees with the fabrication of new ones, but at once supply the vacancy by the substitution of worker-comb. Spare combs are so valuable for this and other purposes that we preserve them most carefully, and neglect no opportunity of adding to our store.]

CUTTING OUT COMBS.

PLEASE inform me if it be possible to cut out combs from a strong stock in a common hive. The whole stock, I should think, weighs at least 30 lbs.; but the bees will not work in a super. Having no bushes in our garden we lost our first swarm from this stock in May, and since then we have driven a swarm from it into a common flat-topped hive, where the bees are working famously. The old stock seems as populous and busy as ever, and we, the landlords, look on, wondering how by fair means or foul we can obtain our rightful share of their produce.—S. S.

[We do not deem it good practice to cut combs out of common hives, especially when, as in your case, a swarm has been secured in addition to the one which was lost—a measure of success with which you may well rest satisfied for the season. If next year you can furnish your super with some pieces of clean worker-comb, the bees will probably take possession of them promptly enough.]

MUSICAL BLACKBIRD.

In reply to Mr. Hewitt's letter, which appeared in your issue of the 5th inst., I beg to inform him that our groom has a blackbird which whistles "O, Susanna," very distinctly, though it seldom goes through the tune without a break, its favourite bar being "Don't you cry for me."

It is the only blackbird I have ever seen that could whistle a tune; but our groom tells me that he once knew a blackbird which whistled "The girl I left behind me" perfectly. He also says that blackbirds are best taught from a flageolet; but I must say that our blackbird's accomplishments are not much to my taste, and are in no way to be compared with the song of its wild brethren.—JAMES SNOW WHALL, *Worksop*.

P.S.—I never before heard of a talking blackbird.

EARLY SWARMS.—A man in this part (South Durham), had a first swarm from a hybrid queen on the 19th of May, and the second and third on the 4th of June. This is very early for this part, as we seldom have any before June 7th, and it would therefore appear that the hybrids are a good cross. Another person had a swarm from a crossed Ligurian queen (crossed last year), on the 30th of May, a very large swarm; and there can be now no doubt that, could the Ligurians be kept pure, they surpass the black bees.—A. W.

MATERIALS FOR WATER PIPES AND TANKS.

In reply to your correspondent "W. T.," I can inform him that galvanised iron is unfit either for the storage or conveyance of water. Water, soft water especially, quickly becomes impregnated with the metal, which imparts to it a hard quality, rendering it unfit for domestic purposes.

The best material for pipes is the enamelled iron tubes supplied by the Crown Tube Works, Wednesbury. The next best plan is to coat the ordinary iron pipes with a strong solution of asphaltum in turpentine. The tubes require heating in order to apply this mixture properly. The same may be advantageously applied to the inside of common cast-iron tanks. In all cases the asphaltum must be used as the cement at the joints in lieu of the red-lead lute that is in ordinary use.

Common pine wood also makes an excellent substitute for iron tanks where purity and cleanliness are essential. This can be coated with the asphaltum varnish. The wooden tank will last twenty years.—G. P. D.

In answer to "W. T.'s" inquiry in your last Number as to iron tanks and pipes, I beg to say, in reference to the latter, that some years ago we laid down iron pipes which were glazed inside and out, the end of one pipe fitting into a socket in the other, and the two being screwed together; washers of gutta percha were used in the sockets to keep them watertight. That must be ten or twelve years ago, and we have never had any trouble with them since, and nothing can be cleaner. I suppose the glass is put on in a liquid or molten state, and the whole surface is thus enamelled over, as it were. I should think tanks could be prepared in the same way.—J. K. J.

"W. T." wishes for information about galvanised iron pipes and tanks. Having had a great deal to do with them I can recommend him to put down earthenware pipes if possible; if the lift is not great they will convey water better than anything else. I have water brought over a little valley with a lift of 15 feet. If the water "W. T." has is hard, common iron pipes will answer perfectly; if it is soft, they must be galvanised or lined with pottery, as they do now-a-days; for soft water rusts the pipes, but hard coats them with lime, and renders them durable and cleanly. If "W. T." has water constantly running, lead pipes will answer his purpose better than anything, but lead will not answer if the water has to stand. Cast-iron cisterns may be painted inside, and will last without another coat for years.—A SOLDIER.

I SHOULD recommend wrought-iron pipes heated and dipped in raw linseed oil while hot, having laid some treated in this way about twelve years since, and upon examination a few months ago they were found to be in a very perfect state. Some galvanised branches had to be taken out, and oiled pipes fixed in their places.—J. W.

OUR LETTER BOX.

SPANISH FOWLS AT THE BATH AND WEST OF ENGLAND SOCIETY'S SHOW.—The third prize was awarded to Mr. R. Wright, Holloway Road, London, and not to Mr. Parsley.

BRAHMA POOTRAS BREATHING WITH DIFFICULTY (S. M.).—We are large Brahma breeders. In damp weather we have known them rattle in the throat for a few days, but have had no such visitation as you describe. It would not in any way affect them for table purposes. It is possible that the new-mown grass may affect them through the nostrils, and cause inflammation of the windpipe. We hazard this opinion because Hamburgs are not affected by it, and they are far more prone to disease than Brahmas. Remove every vestige of the grass. Make your nests afresh on the ground with very little hay, and keep the eggs moistened. Put camphor in all their water. A warm sun for a week will probably cure them. The fowls seem so well that we do not advise treatment. You cannot do better than leave well alone.

LARGE VARIETY OF PIGEONS (G. Bradford).—Your Pigeons from Malta are most likely one of the varieties of Italian Runts.—B. P. BRENT.

DISEASED PIGEON (A Young Fancier).—Your Pouter cock has a core or tumour in his crop. With a sharp knife or scissors cut the crop open, cut the tumour out, wash the crop clean, and sew it neatly up; do not give the bird anything to eat or drink for a few hours, and sparingly at first. The bird may then recover, but much depends on cutting out the whole of the tumour, otherwise it will form again.—B. P. BRENT.

PIGEON DEALERS (A Constant Reader).—You will find such in the neighbourhood of Seven Dials, Club Row, and Hare Street, and Kent Street, Borough, as well as Leadenhall Market, and many other places.

REARING YOUNG LARKS (A Subscriber).—Put the nestlings in a large cage, keep the bottom thickly covered with any sand or earth, and feed them on bread and cheese made into a stiff paste. You may add hard-boiled eggs and crushed hempseed occasionally. You can often pick out a cock bird by comparing it with its fellows, but the surest way is to wait till they begin to sing. The feathers on the Cochins' legs are most likely rubbed off, and will come again when the stumps fall out at moulting time.—B. P. B.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 72.9; and its night temperature 49.6. The greatest heat was 91, on the 30th, 1862; and the lowest cold 34, on the 26th, 1864; 28th, 1832; and 30th, 1863. The greatest fall of rain was 1.15 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

A FEW NOTES ON THE WELLINGTONIA.

EVER since the almost fabulous dimensions of this monarch of the forest in the far west were first reported to us the interest in it has been kept alive by notes from

travellers, by the arrival of seeds, their germination, and the healthy and vigorous growth of the plant in this country. Further, the reports of the magnitude of the tree in its native valleys were confirmed by the outer casing of one of these monarchs of the forest being set up in the Crystal Palace. Since the introduction of the Wellingtonia the demand for it has been duly supplied, and it has been planted in all manner of situations, and not a few plants adorn the front gardens of small suburban villas, where there is not the remotest chance of the tree attaining the dimensions of a medium-sized shrub without being in the way.

The rapid growth of the Wellingtonia seems to place it amongst the first favourites of the day for creating effect in a very short time, and its beauty as a tree, irrespective of the size it attains, gives it a claim which no other plant possesses. Nevertheless with all its good qualities it has its faults, and it is only fair to state these, but fortunately they are neither numerous nor such as cannot be amended, or rather avoided. Its principal fault is that it transplants badly after it has been more than one year in a place. This, I believe, is admitted by all.

The question then arises, Which is the best time to plant it? My own opinion, as well as experience, would point out the early autumn months—say September and October, but this I expect must be accepted with some qualification. In seasons like the last the plants with me grew at least as much after the 1st of September as they did before that time. Would it, therefore, be wise to disturb that growth by transplanting the trees so early? Circumstances often render the delay of transplanting imperative, and it has, therefore, sometimes to be performed at seasons most unfavourable to the welfare of the tree, but it is so accommodating at times when its success is doubtful that unexpected results follow. In my own practice I believe that I have planted Wellingtonias in every month in the year excepting August and September, and I am not certain that these months are not the very best. I have seen carefully lifted a few plants in July attended with tolerable success, and October is very good, but a like result did not follow planting in January; for though a portion of the plants grew well, others died off. I believe April to be better than mid-winter for planting, more especially if the trees have been standing thickly together in nursery rows, for to isolate them in exposed places at that time is, I believe, as hurt-

ful to the tops as to the roots, and they fail. It is probable, therefore, that planting in October will be attended with the best results, and what I have done at that time has been so. There are, however, other conditions proper to be observed in the planting of Wellingtonias, as well as of all other Pinuses, which it would be well to bear in mind; but as failures are equally instructive as successful management I herewith give an example of both.

In the middle of October, 1863, I planted in nursery rows a number of Wellingtonias that had previously been in small 60-pots. None of the plants exceeded 6 inches high, while most of them were not more than half that height. The soil was of a loose open nature, with plenty of stones in it, and it had previously been cropped with Potatoes and other common vegetables. I may remark that during the winter the little plants were anything but promising, and many persons prognosticated their failure. Their brownness was no doubt in great measure owing to their roots being dis-entangled and carefully spread out straight from the collar, which, however, was not always done without fracturing now and then a stiff crooked root; but it was persisted in, for I had seen enough of the evils of transplanting trees that have been some time in pots, and therefore I determined to remove all trace of their having been so treated. The ordeal unquestionably checked growth, and the plants did not commence to grow till the summer was somewhat advanced, but very few of them failed, and the growth of the whole was pretty fair. Two of the plants that I took up that autumn were nicely rooted, and bore the removal well; but circumstances prevented the whole being taken up then, and they remained another year in the ground, where they made rapid growth, most of them being 5 feet high, and well furnished at bottom. The fine autumn, or rather the rains we had in October after a period of very dry weather, prolonged their growth so much that I believe they kept on growing until December, when it was determined to remove them. Here was the error; had we done so earlier, say in October, I believe that we might have been successful, but it happened that we could not do so at that time, and it was January ere they were finally planted out. Although better rooted plants could hardly have been wished for than most of them were, their success has been far from satisfactory, several having died, others partially so, while some have apparently scarcely felt the change, but the latter are in the minority. It may be said that they were allowed to remain too long in their position in the nursery, but two years is not a long time for trees and shrubs in an ordinary way; and some two hundred or more Cupressus Lawsoniana that were treated in exactly the same way as the Wellingtonias, and transplanted at the same time, have scarcely experienced a check, although their growth equalled that of the Wellingtonias. It may, therefore, be set down as an established fact that the latter is one of the classes of plants which do not transplant well after having been more than one year in a place. This is unquestionably a drawback, but it is amply compensated for by the good qualities of the tree.

I will now mention two or three of these good properties

The first of these is its capability of withstanding wind; for the trees in the most places seem to be little affected further than being merely slightly bent in the direction towards which the wind blows, and the plant being more sturdy, and usually better furnished at bottom. Another good property is that of quickly replacing the leading shoot, should any accident damage or destroy the proper one. Several instances of the tree having done this have occurred here. One fine tree, now upwards of 20 feet high, lost its leader twice, it being cut off some 8 or 10 inches each time, and it would be impossible now to discover where this occurred, although these accidents only took place in 1863 and 1864. Another point is the adaptability of the plant to all kinds of soils, light and heavy appearing to be alike suitable; and whether limestone or peat prevail, the tree seems to be equally at home. In general, however, I believe it succeeds best in a deep rich soil, such as we all like for a kitchen garden; but a good healthy subsoil seems as much to its liking as the character of the surface. I have never seen the Wellingtonia tried in a situation where moisture is stagnant, and it can hardly be expected to do in such a place; but to all others it seems to accommodate itself. Its hardiness has been sufficiently tested to place it second to no Conifer in that respect, and many other merits might be enumerated.

Although I have stated that the Wellingtonia transplants badly after being too long in one place, it is but justice to add, that it is by no means one of the worst plants to remove. *Cupressus macrocarpa* is certainly worse, and *Taxodium semper-virens* is not by any means good. In general, *Thuja* and *Thuja* plants transplant well; but, perhaps, one of the most difficult plants to remove with success is the Evergreen Oak.

Those having remarkable trees of the Wellingtonia would confer a benefit on the readers of this Journal, by publishing the dimensions of their specimens. This and other information could not fail to be interesting.—J. ROBSON.

HARDY EUCALYPTUS.

ANY of your readers who may visit Ken Gardens will probably be as much surprised as I have been to see a large tree of *Eucalyptus polyanthemus* growing freely in the open border, and apparently as hardy as any Laurel. Judging from its size, it must have seen the thermometer at zero several times during its existence. In Don's work this species of *Eucalyptus* is not enumerated.—G. S.

BIRTH OF GARDENING IN ENGLAND.

I HAVE been asked and have agreed to deliver a lecture upon the rise and progress of gardening in this country. There is no deficiency of information on its advance since the first Stuart ascended the throne of England, but I cannot resolve where to begin. Will you advise me?—P. T.

[No art is encouraged until there is a popular taste for the subjects within that art's province. Now, there was no taste for either fruits, kitchen vegetables, or even flowers as objects of culture at the commencement of the Tudor dynasty, nor was that taste much developed until the reign of Elizabeth. It is recorded in the reign of Henry VIII. that even salading was imported for the Queen's table; and in the first year of Elizabeth, 1559, a state paper enumerating certain "necessary and unnecessary wares" imported into London from abroad records that "Cabages and Turnops to the value of £157 16s. 8d." were so introduced.

A taste for gardening, both for ornamental and useful purposes, however, was generally aroused in the reign of Elizabeth; and in proof of that we will quote a few passages from the recently published "Calendar of State Papers," edited by Mr. Lemon.

The Royal Gardens seem to have been resorted to for stock to furnish her courtiers' gardens. Thus Armigill Ward, writing to Cecil in March, 1561, says that the gardener at the palace at Greenwich will furnish him with Lavendar, Spike, Hissop, Thyme, Rosemary, and Sage, and if more be required Hampton Court and Richmond can be sent to.

In September of the same year Cecil wrote to Windebank to help him to a man "apt for his garden;" and in the year following to send him over a Lemon, Pomegranite, and a Myrtle tree, with directions for their culture, adding that they may be brought to London with Mr. Carew's trees. They were sent, and Windebank states that the Lemon tree cost 15 crowns, and the Myrtle trees 1 crown each, "which is very cheap."

Bishop Grindall, writing to the same statesman in the August of 1566, expresses his regret that he has no other fruit than Grapes to send him.

We could make many more quotations similarly illustrative of the general awakening of the love of horticulture at that period, but we have published enough to sustain our opinion, but if you desire more we shall be very ready to furnish you with references.]

THE HYBRIDISATION OF FERNS.

ONE of the most interesting of gardening occupations, if not the most interesting of all, is, indisputably, the fertilisation of plants with a view to change the character of species, or to obtain new forms or hybrids.

Whilst we watch with a lively interest the progress of plants which have been fertilised one with the other—a process which in Phanogams is perfectly clear to us, because their organs, whether large or small, can always be distinctly seen, we are, nevertheless, still in darkness as to the fecundation of Ferns and the mode in which it is effected.

The profound and interesting investigations of Münter, Lechinsky, Wigand, Schacht, and others have established the existence in Ferns of reproductive organs of both sexes (antheridia and archegonia), which are borne upon the under side of the pro-embryo (prothallium)—that is, the foliaceous body, which results from the germination of the spore. In conformity with these investigations, which would give to the pro-embryos, so to speak, the character of flowers, most physiologists are of opinion that the artificial fertilisation of Ferns would only take place when the pro-embryos of two distinct species were brought into close contact. The opinion that fertilisation might be effected on the frond at the time of the spores being formed (and this would be analogous to what takes place in Phanogams, and would appear to me more in accordance with the laws of nature), has up to the present time found scarcely an adherent, although from what I have understood, Schacht in his latter days declared himself in favour of this theory.

The above opinion was expressed about ten years ago in "Bonplandia," I believe, by my friend Mons. F. Stange, of Hamburg, but with the details of the article in question I am not acquainted. The experiments which I have made on the hybridisation of Ferns link together, perhaps, the two theories, without admitting either to its full extent. I am inclined to believe that a kind of fecundation takes place at the very moment at which the spores commence to germinate, and when the gelatinous mass of the different spores commingles, and becomes mutually transformed long before a pro-embryo has been produced.

My principal reason for doubting the fecundation of pro-embryos is the fact that a large number of hybrids are frequently found together side by side. Contact between the pro-embryos, therefore, could not have taken place, and it also appears to me that we likewise cannot admit that all these hybrids could have been produced by the mutual opening of the reproductive organs, which takes place as if at a bound. I have my doubts as to fertilisation having taken place on the fronds, because I have obtained hybrids from species which have not been in contact with others of their kind, as I shall now proceed to show.

Some years ago I reported in "Wochenschrift," published at Berlin (1859, page 183), that I had obtained a new and interesting hybrid *Gymnogramma* between *G. chrysophylla* and *G. lanata*. Professors Koch, of Berlin, and Reichenbach, of Leipsic, did me the honour of naming it *G. Stelzneriana*. All the plants of it which I have raised had this peculiarity—namely, that nowhere did they produce spores, although they were in the hands of the most experienced English and German cultivators. I even grew some specimens myself with fronds 3 feet in length, but they did not produce spores, and I believe that the plants which I raised at the above period have now everywhere disappeared. Three years ago I again succeeded in obtaining the same hybrid by sowing *Gymnogramma chrysophylla* and *G. lanata* in the following manner:—I collected on a piece of white paper the spores of the two, and after mixing them as much as possible, sowed them together. In this way I succeeded in obtaining a good proportion of *Gymnogramma Stelzneriana*, which, nevertheless, exhibited two different characters. Some individuals were in every respect like those obtained in 1859, the under side of the fronds being covered with golden dust, and the young fronds slightly crested at their extremities; whilst the others had narrower, more hairy

fronds of less size, and not so powdery. The most singular part of the affair was, that all the plants of each character after less than a year's cultivation yielded perfect spores, which on being sown reproduced the varieties, and their fronds are three times the size of those of their parents. I also made experiments with *Gymnogramma gracilis*, *pulverulenta*, *argyrophylla*, *L'Herminieri*, and *Laucheana* sown indiscriminately together.

The spores of *Gymnogramma gracilis* were those of a plant which I had grown some ten years, when that Fern was quite new, and it was isolated not merely from every other *Gymnogramma*, but also from every other Fern, for it was the only one in the house; the spores of the other species came from plants which had never been in any way in contact either with *Gymnogramma gracilis* or *G. tartarea*. The results were as follow:—

Gymnogramma pulverulenta sulphurea.—Both sides of the fronds were covered with pale yellow dust. I only obtained three plants, which I unfortunately lost in winter.

G. gracilis hybrida, intermediate between *G. gracilis* and *G. lanata*, and resembling *G. tartarea*. Some of the plants are densely covered with a bright silvery dust, others with a yellowish white dust, and in others again it is altogether wanting. All are covered at the base of the fronds with a dense brown down more or less deep in colour.

G. gracilis elegantissima, with very finely-cut fronds densely covered on both sides with a yellowish white powder.

G. gracilis superba, the most ornamental and valuable of all. The fronds, which curve very gracefully, are not nearly so finely cut as in the preceding, but are broad, of a bright glossy green, with a metallic lustre on the upper surface, and covered beneath with a very thick coating of yellowish white powder. This is one of the hardest of all *Gymnogrammas*.

G. hybrida davalliaefolia, the result of a fertilisation of *G. L'Herminieri*. Its merits consist in the number and fineness of its pinnules, forcibly reminding one of some graceful *Davallia*; its fructification is also very ornamental.

Gymnogrammas are readily crossed, but up to the present time other genera have not produced hybrids. I have, it is true, obtained some variations of form, such as *Davallia tenuifolia stricta*, a tufty variety of *D. tenuifolia*, and *Pteris aspericaulis* from the seeds of *Pteris tricolor*, which may, perhaps, tend to prove that the latter is only a hybrid or variety of *Pteris aspericaulis*, and all the more because it is absolutely the same as the latter in its mode of growth. These forms remind one of the hardy Ferns, most of which are so interesting and ornamental, and of which the spores always reproduce the same forms, as I found some years ago by experiment on *Athyrium Filix-femina Frizellia*, and again more recently in the case of *Osmunda regalis cristata*.

Did the last-mentioned forms also result from fecundation? I do not think so, because there are plants, though comparatively few in number, which return to the type after having preserved for a whole year the character of a particular form of that type.

Experience has taught me, as it has many others, that the pro-embryos can be preserved as long as the plants themselves, and that they can be divided and thus serve for propagation where the number of plants obtained is small. All that is necessary to be done is to cut off the young plants with a very sharp knife, always taking care to preserve the pro-embryos. It is more particularly to those of tree and other very large Ferns that this mode of proceeding applies.

My experiments have likewise taught me that a high temperature hastens and is favourable to the germination of the spores, and their hybridisation. I always give a sufficient degree of heat to kill every Phenogamous plant.

As a nurseryman my experiments have naturally been limited, only extending to the most ornamental species sought after in commerce; and for the same reason I could not afford the time and the appliances necessary to attain a definite result if such were possible. It is the part of practical gardeners to perform horticultural labours with intelligence, and to observe the facts and appearances which serve to guide men of science in profound and intricate investigations.—A. STELZNER (*Bulletin du Congrès International de Botanique et d'Horticulture à Amsterdam.*)

PEAR BLOOM ON THE YOUNG WOOD.—A Pear tree, which I believe to be the Easter Beurcé, growing on a wall at Fordham Abbey, is well covered with fruit as large as Walnuts. At the

same time a shoot of the present year, has a bunch of blossoms (unfertile) fully expanded.—W. C.

NEW SEEDLING ROSE—MRS. WARD.

I HAVE received from Mr. Ward, the raiser of one of our most renowned English Roses—John Hopper, some blooms of another seedling of his own raising, which, I do not hesitate to say, will in my opinion prove a worthy competitor to that celebrated flower. Not content to run into the common track, and to add another to the many children of Général Jacqueminot with which we are already inundated, he has taken as the parents of his seedlings Jules Margottin and Comtesse Cécile de Chabillant, two of the very best Roses we have; and in the case of Mrs. Ward he has obtained a Rose which partakes most clearly of the qualities of both parents. In shape it is like the Comtesse, beautifully shell-like, with very thick petals. As to colour, it has the colour of Jules Margottin in the centre of the flower, and that of the Comtesse in the outer petals. In habit it partakes of the character of the Comtesse (which, strange as it may sound, is the male parent, the wood being very stout and spiny. I know Mr. Ward's ground well—worse Rose ground I do not know; and I am quite confident that when this Rose is grown in good strong soil it will prove to be one of the very finest exhibition Roses we have. I have been lately through the Rose gardens of Lyons and Paris, and I have seen no new Rose equal to this, and I consider Mr. Ward to have been most fortunate in raising it. I was not wrong about John Hopper, and I am tolerably certain I am correct in my estimate of Mrs. Ward also.—D., Deal.

WEATHER WISDOM.

(Continued from page 318.)

The report of a Committee appointed to consider "certain questions relating to the meteorological department of the Board of Trade" has recently been issued,* and I think that a few extracts therefrom will not prove uninteresting to those of your readers who have neither the time, will, nor the opportunity to wade through the pages of a parliamentary blue book. The subject of the report is intimately connected with "weather," and the book is well worthy of the study of these who try to attain to "weather wisdom."

The first part of the Report treats of the meteorology of the ocean; the second, of "The prognostication of weather in the British isles, together with observations of the changes of weather within or near these limits, for the purpose of ascertaining the laws upon which such prognostications are or ought to be founded." It is to this section of the report that I now purpose calling the attention of your readers.

The practice of telegraphing and foretelling weather began with the late Admiral Fitzroy (see Report, page 17). Storm-signals were hoisted for the first time in February, 1861, and in August of the same year daily forecasts of the weather, of which a specimen is given in the Appendix, page xxix., appeared in the newspapers (Report, page 19). This system it seems was not confined to the British isles alone. The Report says, "M. Le Verrier has organised a system of storm-warnings similar to our own. For some time his bulletin contained predictions of the probable weather for different parts of France, but we observe that these daily predictions have been recently discontinued." At page 19 of the Report, the public are initiated into the mysteries of English weather-forecasting.

"In making daily forecasts, the area of the British isles is divided into districts, and the average state of the weather in each district is deduced from the weather reports received from the stations contained within it.

"A daily forecast for each district is then made provisionally. The separate forecasts are next collated and revised, regard being paid to the following particulars:—

"(a) The mutual actions of the estimated weather in each of the districts of the British isles.

"(b) Scattered information in respect to such distant areas of high and low barometer as the continental stations can afford.

"(c) Geographical conditions of mountain, plain, or sea, by which the free movements of the air may be affected.

"It is the custom of the department to perform the whole of

* "Report of a Committee appointed to consider certain questions relating to the Meteorological Department of the Board of Trade." London: George Edward Eyre, and William Spottiswoode. 1866.

the foregoing operations, and to determine the forecast after a simple inspection of the list of weather-returns. No notes or calculations upon paper are made. The operation occupies about half an hour, and is conducted mentally."

In Appendix, page xx., are certain maxims, which it appears are employed by the department in forecasting weather. "Some of them," says the Report, "rank among the long-established truths of meteorological science, while others are clearly open to considerable doubt."

The Committee next compared the daily forecasts with facts, and with each other. They report, "though it is under the circumstances impossible to make an exact comparison of forecasts with facts, it is possible to make an exact comparison of the forecasts with each other—i.e., to compare the forecast for Thursday made on the Tuesday with the forecast for Thursday made on the Wednesday. * * * * * The forecasts made on two succeeding days for the third day differ from one another in every possible way." Your readers will not, I believe, after such a statement be surprised at the report of the Committee, upon the utility or inutility of daily forecasts (page 23). "As regards the utility of the daily forecasts, we have to observe in the first place, that if there is no sound basis on which they are founded, and no evidence that they have been correct in point of fact, they are wanting in everything which can render them practically useful. But even independently of this, we doubt whether intimations of ordinary coming weather so vague as these forecasts must necessarily be, can be of any real value. If it were possible to tell the sailor in a particular part that the wind for, say, twenty-four or forty-eight hours would be westerly, or to tell the farmer in a given district that he would have rain within that time, or to tell the gardener that his crops would need protection from frost or hail, or to tell the traveller that the weather would be propitious for his journey—these predictions if correct would be useful. But nothing of the kind is attempted. The forecasts indicate, as the department has repeatedly stated, merely the opinion of the department concerning a probability. They extend to large districts without attempting to describe the varied particulars of weather in different parts of those districts, and they thus fail to give that information which alone could make such predictions of practical value." Very soon after occurs this important passage: "And we may add that we can find no evidence that any competent meteorologist believes the science to be at present in such a state as to enable an observer to indicate day by day the weather to be experienced for the next forty-eight hours throughout a wide region of the earth's surface."

Next as to the storm-signals. Storm-warnings seem to have been more satisfactory, though there is considerable room for improvement. How these warnings have been appreciated may be gathered from the abstract of opinions concerning the value attached to them at the present time (see Appendix, page xxviii.)—opinions certainly most favourable. The Committee themselves say (page 34)—"There would be great regret if they were discontinued." And further on (page 42)—"The system of weather telegraphy, and of foretelling weather, is not in a satisfactory state. It is not carried on by precise rules, and has not been established by a sufficient induction from facts. The storm-warnings have, however, been to a certain degree successful, and are highly prized."

In conclusion, the Committee pay a tribute to the energy and devotedness of the late Admiral Fitzroy. "To his zeal and perseverance is due the credit of establishing a system of storm-warnings, which is already highly prized by the seafaring class. And if a more scientific method should hereafter succeed in placing the practice of foretelling weather on a clear and certain basis, it will not be forgotten that it was Admiral Fitzroy who gave the first impulse to this branch of the inquiry, who induced men of science and the public to take interest in it, and who sacrificed his life to the cause."—*X., Surrey.*

BIRMINGHAM ROSE SHOW.—Friday, the 29th inst., is the last day on which entries can be made to exhibit at the forthcoming Rose Show, to be held in the Town Hall, Birmingham, on Thursday and Friday, the 5th and 6th of July next. If the copious rains which have recently fallen are followed by such warm sunny days as we may reasonably expect, there can be no doubt about the quality of the Roses which will be staged. Indeed, in that event we may venture to anticipate that the days fixed for the Show will prove most fortunate for catching

the Roses at their very best. Manufacturers of whatever is of interest to the amateur or professional gardener, either to use as an implement or otherwise, or as ornaments in the garden or greenhouse, have every inducement offered to send their goods to this Exhibition. We hope there will be, as usual, a good and varied display.

A PEEP AT THE WOODS IN ODD PLACES.—No. 8.

THE MISSISSIPPI.

"AND a half four!" sings out a lusty voice, and immediately afterwards another voice, which I recognise as that of the captain, exclaims "Stop her!" and I at once feel that the engines are stopped, and then I hear a shout of "Stand by the anchor!" and then, "Let go!" on which follows a heavy splash, and then a tremendous rattling, which shakes the vessel from stem to stern. I quickly tumble out of my berth, and dressing, go on deck, where I find already assembled a large number of passengers, all anxious to know what is the matter. "Nothing, my dear friends, nothing; we have only arrived off the bar at the mouth of the Mississippi, and have come to an anchor to wait until such time as the pilot thinks he can drive her over, as there is here a slight rise in the tide; but we draw some inches more water than there is on the bar, and another large American steamer has stuck in attempting to cross, and lies in the deepest place, so you may rest quietly, and in the afternoon or early to-morrow morning we shall endeavour to get over and steam up the stream to New Orleans. It is not far, only a little more than a hundred miles, and we shall soon be there."

"Go a-head!" exclaims the pilot, and we are once more under steam and steering for the bar. We cross it safely and without sticking, although we have had a hard push through the mud, and now we are in fourteen fathoms of water, with no fear of grounding, unless we run on the banks or some spit; but of that there is no fear, as our pilot is well acquainted with the river, and it is deep enough and wide enough for any craft that can possibly enter. So, now being safe, let us take a look around that we may know in what sort of country we are.

On both sides we see long, low, flat banks—that is, we fancy we see them, for in reality we do nothing of the kind, since that which meets the eye, and appears like *terra firma*, is composed of a continuous bed of reeds growing on the silt, *débris*, rotting trees, and general rubbish, which has been earned down generation after generation by the mighty "Father of Waters," that being the interpretation of the Indian name Mississippi. Reeds, reeds, nothing but reeds, except where diversified here and there by a dead tree, brought down by the current and stopped on the edge of some mud bank to assist in forming an islet, which will be joined on in course of time to the mainland; nothing but reeds till we reach Pilot Town. All this stream, although so close to the sea, is fresh water, or at least quite drinkable, and these reeds are exactly similar to those we find at home in the ponds and pools of old England.

Soon after passing Pilot Town the banks on one side begin to rise a little, and stunted specimens of trees, or rather bushes, begin to show themselves, the first to be noticed being Willows; and it has a very strange appearance that, whilst the banks of the river have a green margin, all the back portion of the country presents on one side an undulating surface of greyish brown from these reeds, whilst on the other we are divided from what is absolutely salt water by a very narrow neck of land. The bed too, of this fresh-water river will be at least from 5 to 7 fathoms below that of the sea divided from it by a strip of land, in many places not exceeding 100 yards in width. Proceeding further up the stream vegetation begins to be a little more varied; the Willow bushes are of larger size, and the Cedar begins to show itself—small, miserable, and stunted at first, though of a much finer growth as we proceed; and here again, in place of cormorants, pelicans, cranes, and canvas-back ducks, we begin to meet with small land birds, kingfishers, turkey-buzzards, and crows. Speaking of cranes and turkey-buzzards, I cannot help mentioning a curious little scene presented to us going up, which would have made a really pretty vignette. Passing along the bank within a distance of a very few yards we came suddenly upon a nook, the edge overhung and shaded with reeds, Willows, and Cedars, whilst the mud from the bed of the river ran quite up to them, forming a bank uncovered by water. Upon this lay, dosing in a half torpid state, for it was now far on in November, a large alligator, about 12 feet long, whilst washed up in one angle of the nook

was the carcass of a bullock, around which were congregated a number of turkey-buzzards, and not far off on the edge of the water were standing three beautiful white cranes in all dignified solemnity, looking out for fish, and, to fill up the whole picture of life, numbers of blackbirds flitted about amongst the branches.

These blackbirds are not like ours, although they are so called, for whilst ours are only found in pairs, these are often seen in flocks of many thousands, not being like our beautiful bird stationary and possessed of a delicious note, but migratory and songless, at least only uttering a snatching twitter, not at all like a song, and quite unlike the rich mellow tones of our own exquisite yellow-beaked friend. These seem to belong to all parts of the American continent, for a friend of mine tells me that he has seen them by thousands in Texas and on the Amazon, and I have myself seen them equally plentiful in Canada and Louisiana. The kingfisher which we see on this river is likewise common in Canada, being a bird with a body about the size of a cuckoo, with a large crest, and the plumage white underneath, and blue-grey on the back.

We now begin to see patches of cultivated ground on both sides of the river and trees of some magnitude, along the bank, or levee as it is here called; for a firm, solid bank runs along each side to keep the water from overflowing the land, and this bank has to be kept in repair at the expense of the planters whose property runs up to it, each bearing the expense of such portion as borders his estate. This tax falls very unevenly, since some large plantations are only very narrow, and run directly up from the river, leaving only a small portion of the levee to keep in order, whilst others not nearly so large lie along the bank, and consequently give a much greater extent to attend to, and therefore cause the proprietor much more expense. These plantations were before the war in a most thriving condition, being many of them of very large size, and employing a great number of negroes, and it is most melancholy as you pass up the river to see so many really beautiful houses, with their accompanying little hamlets of nigger quarters, almost entirely untenanted and deserted, whilst noble sugar mills look cold and neglected, with broken doors and other unrepaired damages, and without a vestige of life about them save in the luxuriant growth of rank herbage, silently but surely working out the ruin already begun, and covering with a green leafy veil the rottenness and decay it has already been so instrumental in producing.

All this, however, is now being altered, and the plantations will speedily be brought to their former state of cultivation and richness, though it is very doubtful whether such can be the case with free coloured labour; for niggers will not work like white men, treat them and pay them as you will, for they are naturally careless, lazy, and thoughtless, and certainly carry out the principle, "Sufficient unto day is the evil thereof;" yet there is such a large amount of emigration setting in from Europe towards the Southern States that the nigger will be compelled to work, starve, or migrate. It would indeed be a good thing for America should the blacks be "wiped out" from among its people. England has paid dearly enough for the emancipation of the negro in her West Indian Colonies—property depreciated to an almost fabulous extent, the emancipated slaves became saucy, idle, and truculent, and at last they culminated in attempted rebellion. I can only say, after a considerable acquaintance with the blacks, May they get their deserts.

What can that fine-looking house with the verandah round it be, placed in a beautiful garden with the walk up to the front entrance bordered with noble Orange bushes in full bearing? I call these bushes advisedly in contradistinction to Orange trees, for those which line the drive or pathway up to the main entrance of a Louisiana planter's house are strictly bushes, and often slashed or clipped in the same manner as the trim neat hedges in many parts of England are treated, or as the evergreens such as Yew, Holly, Portugal Laurel, Box, &c., used to be trimmed into those strange, precise, uncomfortably neat-looking, unnatural shapes which used to so delight our ancestors under the title of the Dutch style of gardening, and on which one cannot look without visions of stately dames in long-waisted dresses, with hoops (not the present degenerate flimsy fashion, all sweep, shake, and nothingness, like a balloon, which, being ript, collapses, but good stiff wooden tub-hoops that would stand a push without giving way), and beaux got up extensively in powdered periwig, huge white cravat with lace ends, ruffles, sword, and all the et-cetera of a swell of the year 1700, or thereabouts.

The Orange bushes in these gardens as well as the trees are tended with great care. They produce a most delicious fruit, and bear the soubriquet of Creole Oranges to distinguish them from those brought from Havanna, these latter being generally smaller, redder-skinned, and lacking the peculiar sub-acid so agreeable and remarkable in the Creole fruit, which is also very much more juicy than its foreign relative. Many of these trees are most enormous bearers, and I have heard of one tree which produced 1300 Oranges in one year, though I think this must be a slight exaggeration, since 500 are considered a large yield, but it is a fact that in many places they are so plentiful as to be scarcely worth gathering.

We will now pass by this Orange-orchard with its lovely dark and bright green foliage, golden fruit, and delicious perfume, and get over the fence into that field of what appears to European eyes to be either enormous coarse succulent grass, or most gigantic Leeks planted in rows and carefully weeded and kept in a clean condition. This is a sugar cane plantation, and as the cane is ripe we see hands in another part of the field cutting it and laying it in rows ready to be taken away in carts and passed through the mill, whence, after the juice has been expressed, it is again brought to be used as fodder for the cattle, they being very fond of it, and growing excessively fat upon it. However, whilst we are talking, and it is tremendously hot, let us go under the shade of these trees at the edge of the forest; but, as it is somewhat low and swampy, look out for snakes and alligators, though give them time and either will get out of your way. "Oh! how lovely, how picturesque, how very elegant!" I fancy I hear some of my lady friends exclaiming, as we look at these tall straight-limbed trees; and yet how solemn and funereal is the scene before us! and what a strangely striking object is that noble tree which seems to be clothing itself in grey weeds and plumes ready for its approaching death, for as it adds to its mortuary banners so does it become choked and its sap dried until it becomes a leafless barkless trunk. This is caused by a parasitic plant here indiscriminately called Moss and Barbe d'Espagnol, which grows on the branches of the trees, hanging in long elegant sweeping weepers somewhat after the manner of the Weeping Willow, in colour of a dull greenish grey, and often covering the tree from its very top to the ground. This moss is most useful, and much employed in New Orleans and the Southern States for stuffing mattresses. It is very full of insects, and therefore needs preparation before it can be applied to this use; it is consequently buried for some time, and after a certain amount of decay has taken place it is uncovered and thoroughly well washed and dried, when it presents somewhat the appearance of very rough coarse black hair, and it makes a light, elastic, tolerably durable mattress.—A SURGEON.

LONICERA AUREO-RETICULATA BLOOMING.

This truly beautiful hardy climber is now in full bloom in my garden; and as I have never heard of its having bloomed out of doors in this country before, it occurred to me that many, who, like myself, have cultivated it for the beauty of its foliage alone, will be glad to hear that it can be flowered. It may be well to add that it has been grown on a front wall of a lean-to greenhouse with a south aspect, and that owing to the lowness of the wall we have had to keep it well cut-in, and this has, probably, forced it into bloom.

It is deliciously scented, and should be grown by every one.—J. B. SAUNDERS, *The Laurels, Taunton.*

RED LEAD FOR PRESERVING SOWN SEEDS.

In regard to what was stated in your number of the 19th inst. with respect to the protective character of red lead for seeds, I can state from an experience of some years that I have found it thoroughly effectual against both birds and mice.

I adopted it in consequence of a recommendation to that effect in your pages, and the method of preparation was the same as that described by your correspondent. Early-sown Peas thus coated over have always remained untouched; and even when they are above ground, mice, which so commonly in hard weather then attack them, leave the crops free from injury.

I have since adopted the same plan on my farm for Wheat, Barley, and Oats, and with equal success. Birds, which abound with us, and other birds, will have nothing to do with corn thus protected; and there is this advantage—that there

is no risk of destroying game, or infringing the Act of Parliament against the use of any poisonous preparation for this purpose. Much, too, is thus gained by liberating children from the miserable work of bird-watching, and thus doing away with this common pretext for keeping them away from school.—W.

ROYAL HORTICULTURAL SOCIETY.

JUNE 19TH.

FLORAL COMMITTEE.—Messrs. Veitch exhibited a large collection of beautiful and interesting plants. First-class certificates were awarded to *Adiantum* sp. nova, with the younger fronds of a dark rosy hue; *Verschaffeltia splendida*; *Areca Baneri*, a graceful Palm; and *Gloxinia Prince Teck*, a very beautiful white and pale purple flower. Special certificates were awarded for *Drosera capensis* and a very fine specimen of *D. dichotoma*, curious plants which attracted much attention; also for cut specimens of the beautiful *Fremontia californica*, a hardy flowering shrub. A special certificate was likewise awarded for Messrs. Veitch's general collection, in which were *Drosera spatulata*; *Herrania pahnata*, which received a first-class certificate early this year; *Jussiaea* sp.; *Palava flexuosa*; *Maranta Lindenii*, a very beautiful plant, which it was requested should be sent again; *Alternanthera versicolor*, *spatulata*, and *amoena sessilis*, new plants to be used for bedding-purposes on account of their brilliant dark red variegated foliage; *Nepenthes* sp. from Ceylon, *Aerides maculosum speciosum*, and *Aerides affine*. Mr. Bull received a first-class certificate for *Verschaffeltia splendida*, and one of the second-class for *Athyrium costale dissectum*, also for *Ophiopogon spicatus foliis argenteo-variegatis*. A special certificate was awarded for his two collections of Pelargoniums, representing the Zonale and Show sections. Among the Zonales were some exquisite flowers, the mass of varied colours had a brilliant effect, and although grown in very small pots there were some fine trusses. Some new seedlings were among them, but were not entered for special examination. Mr. Bull also sent *Maranta Lindenii*, which it was asked should be sent again; *Asplenium leptophyllum*, closely resembling *moanthemum*, *Nephradium molle crispum*, and *Nephradium molle grandiceps*.

Messrs. Smith, Dulwich, received second-class certificates for seedling Zonale Pelargonium Vandye, with foliage much like that of Beauty of Oulton, and pale salmon-coloured flowers, a very distinct variety; and for Zonale Pelargonium Glorious, a well-formed, extremely vivid scarlet flower. A commendation was given for Zonale Pelargonium Lucy, one of the marbled section, of which Sheen Rival is a type. It is of dwarf habit, has deep-zoned foliage, and bright scarlet trusses, and is a very effective plant for bedding-purposes. There were several other seedlings of considerable merit from the same firm, but not sufficiently distinct from others; also, *Petunia Jno.*, a striped variety; *Petunia Minnie*, a liliptian form; and Pelargonium Sultan, one of the Show varieties.

Messrs. E. G. Henderson, Wellington Road, exhibited several nice plants. First-class certificates were awarded for Pelargonium Pink Nosegay, and Gloire de Nancy, a continental double variety, of which mention was made in our last report. From the same firm came also four seedling varieties of *Cinthus Damjiri*; one of them producing partially white flowers, the keel being quite white, was awarded a first-class certificate. *Jasminum var. aurea*, and a seedling Zonale Pelargonium, *Christine Nosegay*, were also shown by Messrs. Henderson.

Mr. Pilcher, gardener to S. Rucker, Esq., exhibited some splendid Orchids. First-class certificates were awarded for *Cattleya Warneri*, C. Rackeri, C. Pilcheri, three most superb varieties of *C. labiata*, and a special certificate was awarded for a very handsome specimen of *Lælia purpurata*. Messrs. Osborn, Fulham, received a first-class certificate for an English Orchid, a variety of *Orchis maculata*, called *Orchis maculata superba*; this beautiful and interesting variety was found in Ayrshire, and is distinct from the ordinary form, the foliage not being so long or pointed, and it is covered with minute spots. A special certificate was awarded to the same firm for a fine specimen of *Osmunda regalis cristata*. Messrs. Osborn also exhibited a specimen of an old plant, *Cyrtanthus angustifolius*, and *Cochlearia aculis*, a dwarf annual for bedding-purposes.

Mr. Salter, Hammersmith, exhibited a beautiful collection of Pyrethrams, which was awarded a special certificate; also, two Zonale Pelargoniums, *Madame Werle*, a white ground, with pale pink centre, and *Imperial*, the most perfect in form, and in every respect the best Zonale yet seen, bright orange scarlet flowers, well defined zonal foliage, and good habit. This is a continental variety, and has certainly eclipsed *The Clipper*, and all its class. A first-class certificate was given to each of these plants.

From Messrs. Backhouse came a specimen of *Odontoglossum hastatum*, and from Mr. Williams, Holloway, several fine specimens. First-class certificates were awarded to him for *Orchis maculata superba*, *Calanus Impératrice Marie*, and a tasselled *Adiantum*. In Mr. Williams's collection were also *Dieffenbachia gigantea*, *Teliumthera ficoides*, and the three *Alternantheras* exhibited in Messrs. Veitch's collection.

Mr. Turner, Slough, sent some very magnificent seedling Pelargoniums of the Show varieties; these were selected from the seedlings of

the eminent raisers Mr. Hoyle and Mr. Nye. First-class certificates were awarded for *Perfection*, *Archbishop*, and *Milton*, three very excellent flowers; one of the second-class for *Beauty of Windsor*; and a commendation for *Negress*, with pure white centre, the darkest Pelargonium yet raised. Had the petals been smooth and firm it would have been a first-class plant. It will form a most useful flower for a contrast. A first-class was also awarded to Mr. Turner for a seedling *Pink Princess of Wales*, and he likewise exhibited two seedling fancy Pelargoniums, *Emily Spiller* and *Liberty*. We must not omit to notice the superb and well-grown specimen exhibited by Mr. Turner of *Nosegay Pelargonium*, *Duchess of Sutherland*, which was awarded a first-class certificate last year. We should like very much to see all Zonale specimens shown in the same style. Without doubt Mr. Turner can make as much of the Zonale section as exhibition specimens as he can of the ordinary flowers with which the horticultural world are so well acquainted.

Mr. George Smith, Hornsey, sent a very pretty seedling Zonale Pelargonium with broad white variegation, a very conspicuous variety. Only one plant was shown; its effect could not be properly estimated. James Bateman, Esq., exhibited several cut specimens of Orchids, and a first-class certificate was awarded for *Aerides testaceum* as a novelty. A fine collection of well-grown Zonale Pelargoniums came from the Society's gardens at Chiswick, also some fine plants of the new variegated Maize or Indian Corn, to which was awarded a first-class certificate.

FRUIT COMMITTEE.—The only subjects exhibited on this occasion were fruit of a *Granadilla* from the province of Antioquia, New Granada, sent by J. Peake, Esq., Newcastle-under-Lyne, and of *Zizyphus vulgaris*, shown by J. Bateman, Esq., of Biddulph Grange, whose remarks on both will be found further on.

FORTNIGHTLY MEETING.—S. Rucker, Esq., F.L.S., in the chair. After the election of five new Fellows, and the admission of the Buckinghamshire Horticultural and Horticultural Society into union, the awards of the Floral Committee were reported by the Rev. Joshua Dix.

The Rev. M. J. Berkeley then remarked, in connection with a variety of Portugal Laurel shown at the previous meeting, that *Prunus lusitana* is far more luxuriant in the Azores, Canary Islands, and Madeira than here. At the same meeting there was also a species of *Cotoneaster*, which had proved on examination to be a form of *C. rotundifolia*, which is even more hardy than *C. microphylla*. A species of *Dieffenbachia* had also been brought from the Society's garden, and it had since been shown under the name of *Dieffenbachia Weirii*. On opening the spathe he had found within it a number of other spathes; but it was rather a work of danger to examine *Dieffenbachias*, and he would recommend those making the attempt to be careful. The *Dumb Cane* (*D. seguinii*), for instance, received its name in consequence of its stems when bitten causing the mouth to swell, and producing temporary loss of speech; and *D. Weirii* was also a dangerous plant. Of the variegated Maize it was stated that only a certain proportion of the seedlings came variegated. *Ophiopogon spicatus* and *Eriogonum umbellatum* were then adverted to, after which an unnamed *Sudew* was said to be *Prosera spatulata*. The *Droseras*, of which there were three British and numerous foreign species, were stated to be full of interest; and one in particular, *D. gigantea*, may prove of value as a dye, from its staining the paper between which it is dried a bright magenta colour, which on being treated with ammonia affords a clear yellow. *Ionopsidium acule* was then noticed as being extremely useful for covering ground about plants out of doors, just as the *Selaginellas* are employed under glass. *Fremontia californica*, a flowering branch of which was placed before the meeting by the Messrs. Veitch, next occupied attention, and its principal botanical characters, as well as those of the order *Stereuliaceae*, to which it belongs, were briefly stated. Some doubt was expressed as to whether a plant with very ornamental foliage, exhibited by Mr. Bull under the name of *Samyda nobilis*, was really a *Samyda*, one of the leading characteristics of that genus being alternate leaves, generally marked with pellucid dots, and it was thought to be more nearly allied to *Theobroma*. The pretty *Asplenium leptophyllum* was likewise said to be closely allied to *Asplenium trichomanes*, but to display a great difference in the fructification. Regarding the beautiful *Pyrethrams* shown by Mr. Salter, it was remarked that horticulturists possessed one advantage, that of knowing their whole history from the beginning, and this beginning was a slight change in the number of ray florets observed some years ago by a Paris nurseryman. Now, as an early autumnal flower, the varieties which have since been obtained are equal in beauty to the China Aster, but they have a drawback in being of a more straggling habit of growth, and it would be desirable, if possible, to raise *Pompon* varieties.

Mr. Bateman in commencing his remarks on *Fremontia californica*, said he must first draw attention to the very limited number of hardy shrubs and trees with yellow flowers, which we at present possess. With the exception of the old *Cornus japonica*, the common *Larburnum*, and *Jasminum Wallieianum*, he really could not recollect any such flowering at this time of year. To such, then, the *Fremontia* would be a valuable addition; it was not, however, absolutely new, one plant of it having been imported into this country about fifteen years ago, and that plant was in the possession of the Horticultural Society; but it obstinately refused to be propagated by layers, cuttings, root-division, or any other means, and this was all the more

tantalising because the plant was the only one of its kind in Europe. When the Society got into difficulties, among other assets was this unique plant of *Fremontia californica*, and the nurserymen thinking that they could do what the Society could not, there was a lively competition for it, and it was sold to Messrs. Henderson, of the Wellington Road. By them it was passed from propagator to propagator without success, and at last the plant died. Messrs. Veitch, however, having received a few seeds from the native habitat of the plant, succeeded in raising several plants, some of which were turned out of doors to rough it, at Coombe Wood and in the King's Road, and he had seen a plant of it 5 or 6 feet high, on a wall, and which had been there all last winter and the winter before, and had triumphantly withstood the test. We might, therefore, venture to conclude, that we have here a beautiful hardy plant. As already stated, it belonged to the natural order Sterculiaceæ, and as seen in this country is remarkable for its small leaves, somewhat resembling those of the Shamrock, but in its native country the leaves are as large as those of the Fig tree; and Torrey describes the plant as having much the appearance of that tree. It must, however, be considered much more handsome when covered with its yellow flowers, one peculiarity of which is, that they have no petals, what are seen being divisions of the calyx, or sepals. The plant is found in various parts of the northern portion of the Sierra Nevada, and is named after Colonel Fremont, who at the head of a band of daring men fought his way through hostile Indians and took the site of San Francisco, and the territory thus acquired was annexed to the United States. Colonel Fremont, however, was not only a soldier, but also a good naturalist, and in his first expedition collected three hundred plants, in a second nearly one thousand, but the male which carried them fell over a precipice and they were dashed to pieces, and in a third expedition the fate of his collections was more disastrous still. Col. Fremont, he might add, had become a candidate for the Presidency of the United States, but had been defeated by Buchanan. Botanists had lately been taken to task for their method of naming plants, and among other grievances complaint was made that the native names were disregarded; but the charge could not be established, for botanists where they could did associate such names with plants. Thus in *Jonesia asoca*, *asoca* was the native name. Sometimes, again, something connected with the history of the plant was preserved in the name, and in this way plants would furnish a mnemonic key to a multitude of facts. What a world of history, for instance, there was in the name *Fremontia californica*. There was another plant he might cite, the elegant little *Linnaea borealis*, which was selected to be so named by the celebrated Linnæus. He knew that some pupil of his would name a plant after him, and fearing that it would be some of the gay flowers, such as were in the room, he chose a very distinct, a very humble, and a very modest plant to bear his name—a little Alpine creeper trailing over rocks and crags in Sweden and the Highlands of Scotland, and which, with a little care, would succeed in more southern parts of this country. With regard to native names botanists had done much to euphonise them, and had in many cases adopted them; but there are few, he thought, who would prefer such a name as *corticantozontecoxotzil*, which actually was borne by a *Lælia*, to that which science had given it; and as a further instance that botanists had not neglected native names, he mentioned *Angreacum* which had been euphonised from the native name *agrec*.

With respect to the Orchids exhibited, he would first direct attention to a few from Mr. Anderson, gardener to T. Dawson, Esq., of Meadow Bank, near Glasgow; and to account for their appearance at the meeting, Mr. Bateman said, that having visited that place a few months ago he remonstrated at the fine specimens which he there saw being kept on the north of the Tweed, and he was glad to find that his call had been responded to. He would first direct attention to a magnificent spike of *Odontoglossum Pescatorei* consisting of about sixty flowers, and of which the first blossom had opened on the 18th of March; and this was not a solitary spike, for the plant had produced as many more blossoms on others, some of which came out of the top instead of the bottom of the pseudo-bulbs. Mr. Anderson had, in a paper read at the Botanical Congress, strongly advocated watering Orchids with warm water, but the extraordinary spike, the vigour of the plant, the size of the blooms, almost made one suspect that some stronger drink, mayhap ammonia, had been given. *Odontoglossum Pescatorei* from the colour and long endurance of its flowers was peculiarly a bridal Orchid, and one, too, well adapted for dinner-table decoration, for both of which purposes Orchids offered peculiar resources, and were rapidly rising in favour, and he might add, that the Princess Mary's wedding bouquet chiefly consisted of Orchids. An *opergme* at a dinner party at which he had lately been particularly struck him by its effect, it being dressed with one species of *Saccobium*. To return, however, to Mr. Anderson's Orchids, there was a beautiful specimen of *Oncidium crispum*, and another of *Dendrobium albo-sanguineum*, also a bridal Orchid, its colours being pure white and orange. Mr. Bateman then drew attention to the pretty mauve and pink *Aërides testaceum*, and to the fine specimens of *Lælia* and *Cattleya* exhibited by the Chairman, and remarked that though *Lælia purpurata* is a native of St. Catherine, in Brazil, such had been the greed of collectors, that if the inhabitants want plants of it they must send to London for them. He desired to impress on the meeting that though three *Cattleyas* were exhibited, Warneri, Pilcheri, and Ruckeri, these were not species but varieties—well-marked varieties to which

all due honour should be given, but which, to prevent confusion, he would repeat, should never be regarded as species.

People in the country, Mr. Bateman observed, are often asked by their friends to bring or send to town plants suitable for table decorations, and are at a loss to know what will prove suitable. He therefore begged to bring under the notice of the meeting a plant introduced some two or three years ago—one of the Amoor Vines, and though his own garden had every disadvantage, being cold, high, and in a most wretched climate, the plant was perfectly hardy there. The leaves, as would be seen, had considerable claims to favour in a decorative point of view, and the tips of the shoots were tinged with red. The banks of the Amoor river, the Himalayas, and parts of the Rocky Mountains, are, it was remarked, all that remain from which it could be hoped to gather much in the way of new plants.

Mr. Bateman then directed attention to a few more Orchids, among which were *Maxillaria venusta* with exactly the fragrance of *Gardenia radicans*, a species of *Burlingtonia*, likewise very fragrant, *Eriopsis ruidobalboni*, and the showy *Epidendrum vitellina*.

Passing from the domains of Flora to those of Pomona, said Mr. Bateman, Mr. Peake had exhibited two *Granadillas*, from Antioquia, but though he (Mr. Bateman) had not learnt the opinion of the Committee, he believed that the fruit had proved agreeable. The pulp and seeds enclosed in the rind had much the appearance of frog's spawn. Of tropical fruits not generally grown, he believed that the *Granadillas* were the only ones likely to repay the cultivator. He had himself a house devoted to the purple *Granadilla*, and his family were very fond of the fruit. Recently a Mr. Hullett had been sending about an account of what he termed *Passiflora macrocarpa splendens*, which was described as an extraordinary species from South America, forming a tree that fruits readily in our stoves, and producing flowers 7 inches in diameter, and fruit weighing upwards of 10 lbs. It was also described as a climber. It had been offered to half the price, and, Mr. Bateman added, he did not know how many of the *ditto* *minores*, himself among the number, and the price asked for so extraordinary a plant was high—five pounds. Now, as no one knew anything of *Passiflora macrocarpa splendens*, except by Mr. Hullett's description, and as botanists were unacquainted with any such species as *Passiflora macrocarpa*, or with any *Passiflora* approaching to that in the size of the fruit which it is said to produce, Mr. Bateman hoped that Mr. Hullett would come forward at the next meeting and give the history and particulars of so extraordinary a fruit, and especially the collector's name, and where and when the plant was found. This would be the best possible advertisement, and it would, therefore, be to Mr. Hullett's interest to do so.

Mr. Bateman then directed attention to the fruit of the *Zizyphus vulgaris*, sold in Covent Garden Market as "Japonicas," and which constitute a pleasant addition to the dessert. From these the jububes of the shops are supposed to be made; but, as in the case of some which he had purchased at a chemist's shop that morning, it had been found more easy and profitable to concoct a mixture of liquorice and gum arabic and sell it as the veritable jubube. In concluding his remarks, Mr. Bateman said that he hoped to bring before the next meeting a culprit which had done great mischief in certain parts of Cheshire—*Sirex juvenens*, a large boring insect, which was figured by Curtis thirty or forty years ago when it attacked the roof of York Minster, and at the time it was predicted that it would greatly increase the danger in case of fire, and singularly enough a year or two afterwards the Minster roof was burnt.

THE PRESIDENT'S CONVERSAZIONE.—The Duke of Buccleuch issued invitations for a conversazione on the 10th, and it was attended by about two thousand of the Society's Fellows, and others. A more brilliant assembly could not be easily devised. The entire floor of the conservatory was cleared of plants, and carpeted; the pillars sustaining the roof were surrounded by flowers pyramidally grouped in baskets encircling the pillars. These flowers were gorgeous, yet most artistically arranged, and admirably relieved by the healthy foliage of the giant Ferns, Conifers, and climbers, which are the permanent tenants of the conservatory. The statues embowered among the foliage, and the whole illuminated from above by the close heading of lights round the entire architrave within the roof, was so effective as to realise the descriptions which we read in oriental tales. The Prince of Wales was one of the visitors.

TO MARKET GARDENERS, VEGETABLE GROWERS, &c.—A series of large drawings is being prepared for the food department of the South Kensington Museum, to consist of some of our principal kitchen-garden plants, the object being to show what perfection and magnitude certain plants will attain under judicious and careful cultivation. Any of our readers possessing specimens of the following are asked (if so disposed) to forward them for painting, carriage paid, with roots and all leaves attached, to the artist engaged, Mr. W. G. Smith, 12, North Grove West, Millmay Park, London. The grower's name will in every instance be attached to the portrait of the particular plant painted. List of specimens required—Cabbage, Broccoli, or Cauliflower, any sort, Turnip any sort, Carrot, Parsnip, Celery, and Sea-kale.

CRYSTAL PALACE ROSE SHOW.—JUNE 23RD.

THE extreme lateness of the season tended, as I feared it would do, to diminish the number of exhibitions in Roses, while the fearful storm that burst over London on the night of Thursday completely destroyed the hopes of metropolitan growers; so that on the whole I have never seen so limited a display at the Crystal Palace as on the present occasion. On the other hand, many most remarkable blooms were exhibited, and I should say that as a general rule they were quite in character.

Leaving to other hands the details of the prize list and notes on the general run of flowers, I would just notice the new Roses, which were indeed not numerous, being only exhibited by Messrs. Paul & Son, who took the first prize, and Mr. Keynes, who was second. In the boxes of the former gentleman I observed Madame Moreau, a large flower, something like the old *Boule de Nanteuil*; Mademoiselle Amélie Halphen, likely to be a desirable Rose if full enough, the colour is pretty and chaste; Centifolia rosea, rather too thin, I fear, but a pretty Rose; Xavier Olibo, a splendid dark Rose, and I believe likely to be a valuable addition to our dark Roses; Rev. H. Donbrain, good; Souvenir de Wm. Wood, a very dark Rose, in the style of Prince Camille de Rohan; Madame Victor Verdier, very fine; Duchesse de Medina Celi, likely to be a good Rose if it have stuff enough; Frederick Bibrod, fine shape, and a very pretty new Rose; Seedling No. 3, very promising, dark fiery red, and good shape; Seedling No. 4, fine shape, and nice rosy colour; Eugene Verlier, very dark; Lord Macaulay, very good, but very like *Senateur Vaisse*; Pierre Notting, a full dark Rose; Monsieur Boucenne, very dark, velvety, and good; Souvenir de Dr. Jamin, a very dark bluish violet; John Keynes, very fine if it come full enough; Achille Gonod, a showy rosy red flower.

In Mr. Keynes's collection I noticed Charles Margottin, very showy; Gabriel de Peyromy, well-shaped; Xavier Olibo; Madame Victor Verdier; Comtesse de Paris; George Prince, good in shape but common in colour; Marguerite de St. Amand, a very fine flesh-coloured flower; Joseph Finla, large and good; Louis Van Houtte, a very full and good flower if not too full. Besides these, I noticed in one of the other stands Hippolyte Flandrin, a fine, full, rose-coloured flower, and Madame Fillion, in the same class, very good. There is one Rose I have not mentioned, not because it was not good, but because I believe it to be the *facile princeps* of all the Roses of the last three years—viz., *Maréchal Niel*: it was not only exhibited among the new Roses, but shone conspicuously in every winning stand of the day. It is a grand Rose, and I have good hope will prove hardy, at any rate in the south of England. This is the more to be rejoiced at, as I am sorry to say the hope of a yellow Perpetual is still one of the dreams of the future. I shall have more to say about this by-and-by: suffice it now, that I believe, to the intense disappointment of Lacharme himself, his Rose is not yellow.

Need I add that, as usual, the arrangements for all concerned were of the best possible character—that Mr. Wilkinson, as usual, proved himself the most courteous and efficient of superintendents—a brilliant day brought a crowded company, and proved that large shows are not a failure?—D., *Dial*.

To the above remarks as to the general character of the Show, we have nothing to add save that in their correctness we fully concur. All, therefore, that now remains for us to do is to give the names of some of the varieties which were seen to most advantage in the different stands, and the names of the prizetakers. This we shall do class by class; but before commencing the enumeration (and little else can be done but a mere enumeration of names), it may be well to remark that a large proportion of the blooms were far from perfect, and others, though large, wanted the desirable degree of refinement. Much allowance, however, should be made for the exceptional character of the season, and the difficulties which Rose-growers had to contend with in consequence of the storm of the preceding Thursday, which rendered unfit for exhibition many of their finest blooms.

Class I. was for ninety-six varieties—a long number, in which only a large grower can hope to compete creditably, and which we imagine might be advantageously reduced to seventy-two, as at the National and Birmingham Rose Shows, still the stands, considering all things, were very good. Mr. Keynes, of Salisbury, in this as in the other Nurserymen's classes, was successful in obtaining the first prize with a stand containing, among others, Madame Charles Wood, Comtesse de Chabillant, Cloth of Gold, La Reine, Xavier Olibo, dark-shaded crimson scarlet, a variety which attracted much attention in this and other stands; Pierre Notting, violet-shaded crimson; Marguerite de St. Amand, rose; Triomphe de la Terre des Roses, violet-shaded rose; Triomphe de Rennes; Prince Camille de Rohan; Madame Rivers; America; Maurice Bernardin; Souvenir de William Wood, almost identical in colour with Prince Camille de Rohan; Vicomte Vigier, Gloire de Dijon, Alphonse Belin, bright and lively in colour; Victor Verdier, Mlle. Bonnaire, white, lightly tinged with pink in the centre, very delicate in colour; Gloire de Vitry, Kate Han-Ling, and *Maréchal Niel*.

From Messrs. Paul & Son came excellent blooms of Charles Lefebvre, Pierre Notting, *Maréchal Niel*, Comtesse de Chabillant, Mlle. Marie Bady, François Lévât, Xavier Olibo, Duke of Wellington, Denis Helye, Alphonse Damazin, Gloire de Dijon, Duc de Rohan, Vicomte Vigier, Alba Rosen, Amiral La Pylouze, Madame C. Crapélet, Madame C. Joinneux, Madame Caillaud, Prince Camille de Rohan, Maurice Bernardin, Charles Wood, Beauty of Waltham, and

last and finest of all, *Maréchal Niel*, a glorious bloom, by far the finest of the many fine blooms exhibited of that beautiful variety. In the stands of Mr. Mitchell, Pittdown Nursery, Maresfield, we remarked John Hopper, very fine; Julie Mansuis, a pretty Tea; Madame C. Wood; Hippolyte Flandrin, very large and full; Souvenir d'Elise, *Maréchal Niel*, Gloire de Dijon, Madame C. Crapélet, Madame Vidot, Caroline de Sansal, General Jacqueminot, and Madame Rivers. From Mr. Turner, Slough, many of those already named were noticeable; also Leopold Premier, Madame Maurin, Comte Cavour, Duc de Cazes, Madame D. Donville, Princess of Wales, Blairii No. 2, Charles Lefebvre, very fine; and M. Joinneux, dark centre, backed by rosy crimson outer petals, forming a striking contrast.

Awards—first, Mr. Keynes; second, Messrs. Paul & Son; third, Mr. Mitchell; fourth, Mr. Turner; fifth, Messrs. Francis & Co.

Class II., forty-eight varieties, three trusses, generally affords a very effective display, and such was the case here. Mr. Keynes again took the first place with, among others, Victor Verdier, *Maréchal Niel*, very fine; Madame Sertot, Madame Charles Wood, Madame Moreau, *Senateur Vaisse*, Pierre Notting, Marguerite de St. Amand, Vicomte Vigier, Victor Verdier, Maurice Bernardin, and Centifolia rosea. From Messrs. Paul & Son, the most remarkable were Maurice Bernardin, Olivier Delhomme, Charles Lefebvre, La Brillante, glowing crimson scarlet; Comtesse de Chabillant, Prince Camille de Rohan, very fine; Beauty of Waltham, Princess Mary of Cambridge, Madame Rivers, Xavier Olibo, Madame C. Crapélet, Lafontaine, Mathurin Regnier, and splendid trusses of *Maréchal Niel*. In the trusses from Messrs. Francis, of Hertford, were buds showing prominently above the surface of the stands, thus relieving that flatness which stands of cut blooms usually present.

Awards—first, Mr. Keynes; second, Messrs. Paul & Son; third, Mr. Mitchell; fourth, Mr. Turner; fifth, Messrs. Francis.

In Class III., twenty-four varieties, three trusses, we noticed in the stands of Messrs. Keynes, Turner, Paul & Son, and Fraser, good trusses of many of the varieties shown in the preceding class, Paul Ricaut, Louise de Savoie, Prince Henri de Pays Bas, Anna de Diezbach, Devonensis, and Charles Lefebvre particularly good.

Awards—first, Mr. Keynes; second, Mr. Turner; third, Messrs. Paul & Son; fourth, Messrs. Francis; fifth, Mr. Fraser.

In Class IV., twenty-four varieties, single trusses, and in Class V., twelve varieties, were fine blooms of Souvenir de Malmaison, *Maréchal Niel*, Madame Vidot, Devonensis, Gloire de Dijon, Madame Maurin, Charles Lefebvre, Madame Damazin, John Hopper, and Mrs. Rivers; also Madame Moreau, Marguerite de St. Amand, Achille Gonod, and Belle Normande, all unusually large, but somewhat rough.

Awards—For twenty-four: first, Mr. Keynes; second, Mr. Turner; third, Mr. Walker, Thame. For twelve: first, Mr. Keynes; second, Mr. Turner; third, Messrs. Francis; fourth, Mr. Walker.

In Class VI., for thirty-six trusses (Amateurs), Mr. J. T. Hedge, Reed Hall, Colchester, had fine examples of General Jacqueminot, Le Rhone, Mathurin Regnier, Beauty of Waltham, Cloth of Gold, and *Maréchal Niel*; and Mr. J. W. Chard, Salisbury, Madame C. Wood in beautiful condition, and John Hopper large and fine. In other stands were very good examples of Madame Victor Verdier, Emile Duhae (beautiful bright rose), Comtesse de Courey, Triomphe de Caen, Prince Camille de Rohan, Princess of Wales, Madame Bravy, Maurice Bernardin, and Niphotos, the exhibitors being Mr. A. Moffat, gardener to Hon. Mrs. Maynard, Dunmow; Mr. Wright, gardener to Mrs. Ramsden, Twickenham; Dr. Cooper, Slough; and Messrs. Plester, Ingle, Laxton, A. H. Kent, Bristow, Moore, Marcham, Dennis, Postans, and Hollingworth.

Awards—first, Mr. Hedge; second, Mr. Chard; third, Mr. Moffat; fourth, Mr. Wright; fifth, Dr. Cooper.

In other classes we remarked very good examples of *Senateur Vaisse*, L'Enfant Trouve, Charles Lawson, Madame Boll, Pauline Lanzezar, Le Rhone, Céline Forestier, Comte de Nanteuil, Madame Boutin, Souvenir d'Ann Ami, Caroline de Sansal, Olivier Delhomme, Madame Vidot, Comtesse de Chabillant, Charles Lefebvre, Mlle. Bonnaire, and Maurice Bernardin, and many more might be added if any advantage could result from giving a mere list of names. Taking all circumstances into consideration the amateurs' classes were very creditable.

Awards: For twenty-four, first, Mr. Moffat; second, Mr. Hedge; third, Mr. Chard; fourth, Mr. Stoddart, gardener to J. G. Rebow, Esq., M.P., Colchester; fifth, Mr. Mercer, Staplehurst; extra, Mr. Wright. For eighteen: first, Mr. Hedge; second, Mr. Moffat; third, Mr. Dennis, gardener to H. S. Hayward, Esq., Hurst Green; fourth, Mr. Chard; extra, Mr. Ingle. For twelve: first, Rev. V. Knox Child; second, Mr. Hedge; third, Mr. Ingle; fourth, Mr. Dennis; extra, Mr. W. Lacey, gardener to C. S. Mortimer, Esq., Morden Park.

Baskets or vases of Roses exhibited much sameness, March's stands being, with one exception, employed by all the prizetakers; and the blooms rested on various Ferns at the base, and were interspersed with these in the top dishes. Mr. Ingle, gardener to C. S. Ronald, Esq., Colchester, was first with an arrangement in which the glass stem was entwined with a variegated Jasmine, and Maiden-hair Fern was introduced among the blooms in the top dish. Mr. Hedge was second, and Mr. Marlow, gardener to J. Wigan, Esq., Mortlake, third, both using variegated Japanese Honeysuckle up the stem. Mr. March was fourth with the elegant stand for drawing-room decoration represented in No. 271, and having *Cissus* discolored on the central column. Messrs. Carter & Co. contributed some neat hanging-baskets mossed with

Saliginellas, and filled with Roses, Dracenas, and Corlyline indivisa; and hanging-baskets were also shown by Messrs. Cutbush and by the Crystal Palace Company. The latter were of small size, and suitable for placing on a table or similar position; they were made of wickerwork, and the basket was suspended by a wicker chain from a tripod of the same material. Other baskets were supported on small green-painted iron tripods. The most effective exhibition in this way was the Leicester Vase, measuring from 7 to 8 feet in diameter, and formed of iron ribs some inches apart; and these being tarfed over, the vase was filled with a row of Colons Verschaffelti, then with Geraniums, Mignonette, and Hydrangeas, with a tall pyramidal Fuchsia in the centre.

Roses in pots were not in the fine condition that they were seen earlier in the season. The best twenty-five came from Messrs. Paul and Son, Mr. Turner being second, and Messrs. Francis third. Messrs. Paul & Son also received a first prize for the best twelve sent out in 1865.

Among miscellaneous subjects were Variegated Maize and several pretty tricolor-leaved and Zonale Pelargoniums from Messrs. Carter and Co.; and Messrs. Downie Laird, & Laing, exhibited Wiltshire Lass, a remarkably fine pink variety, which has already been noticed in these columns; fancy and bedding Pansies, of which Imperial Blue was very attractive; an unnamed Zonale Pelargonium with leaves 5 inches across, pale green, marked with a bronzy zone; and Stanstead Kival, with very large salmon scarlet pips. Mr. T. Smith, Long Wittenham, exhibited a Delphinium, called Smithii, with large deep blue flowers with a white eye; and Mr. S. Brown, Sudbury, Invincible Sweet Pea and some pretty early-flowering Gladioli. The most striking of these were Insiznis, rich salmon, blotched on three petals with bright violet; Eclipse, pink and white, and Incomparabilis, cream and violet crimson.

A GLANCE AT THE FLORA OF THE CARBONIFEROUS PERIOD.

BY DR. HORATIO C. WOOD, JUN., PHILADELPHIA.

Read before Pennsylvania Horticultural Society, August, 1865.

ONE of the most curious and interesting discoveries of modern science is that of the vegetable origin of coal. It has become so familiar to us—we are so used to looking on great heaps of coal, and remembering that ages ago they were formed from vegetable matter—that nothing can be more trite than this opening sentence. Yet it is a wonderful discovery, one that awakened strange emotions in the breasts of the earlier investigators, and carried them back, in fancy, to the untold ages buried in the abyss of the past—to the waving forests and thick brakes of that olden time. In the light of more modern science, the fact is still more strangely interesting, as affording an unanswerable example of the indestructibility of a force. For whence did those plants receive the power to draw the immense mountains of carbon from the air and earth, but from the rays of the olden sun? It takes no vivid fancy to see in the glowing, burning coal, the sunlight of a day long fled ere man was: for science, stranger than fiction, can actually measure the power drawn so long since from the sun, and stored away deep in the bowels of the earth, to minister to man's wants. This is not the place to do more than allude to this modern doctrine of the convertibility of force, and its indestructibility. It would be a pleasant task to show how the plant lays hold of the chemical part of the sun's rays and binds them in its cells, making those wondrous little entities so many prison-houses of force. But our task is with the Flora of the carboniferous period, and we must hasten on.

If we subject wood to the action of a slow fire, in the absence of a sufficient supply of air, charcoal is formed, the physical characters of which you are all familiar with. Intermingled with the coal are found small masses of charcoal, closely agreeing in external appearance with that from the Jersey Pines. Further, in and all about the coal are vegetable *relique* in vast abundance and endless variety: huge trunks, many feet in length; innumerable impressions of Ferns; seed-vessels, fruits, leaves, roots—yea, sometimes the stumps of whole forests; and in one or two places on the coasts of Nova Scotia, the forests themselves, standing erect, imbedded in the solid rock. The coal measures are, in truth, Nature's herbarium, where she has stored away the history of the botany of a wonderful period—a botany with strange, weird plants, worthy to grow side by side with the winged saurian lizards, and huge, uncouth, ferocious sea monsters, which make our largest and fiercest reptiles seem but playthings.

The two crowning decisive proofs of the vegetable origin of coal are the following:—First, the fact that if thin slices of it are properly prepared and examined with the microscope, a peculiar structure is visible, so closely resembling that of existent plants, that we often can assert not only the source from

which it has come, but even the classes to which the component plants belonged. Second, the circumstance that the first stage of the formation of coal is at present going on. Of this more will be said after the discussion of the climate and conditions under which the carboniferous vegetation flourished.

Many things have been said and written about the climate of the coal age—some of them more strange and wonderful than even the truth itself. Men have laid hold of the axis of the earth, and turned it to suit their purposes and theories. The great difficulty lies in the existence of coal in Melville Island, Lat. 75° N. The plants brought from that locality seem to be similar, indeed often identical with those found in our coal measures.

The inquiry at once arises in every thinking mind, How could these plants have lived and flourished in that region of ice and snow—that home of frozen death, cold Winter's favorite resting place? The only plants which now grow there are the hardiest of the Alpine flora—even the Birch and the Willow are fain to content themselves with creeping along the ground, not daring to raise their heads more than a few inches into that chilling air; but the coal shows that a flora must have existed there formerly worthy to rival that of the tropics in its luxuriant abundance. Whence, then, the heat and light to foster and nourish such a vegetation? In order to account for the existence of coal so near the pole, Messrs. Lindley and Hutton, two of the most famous investigators in fossil botany, invented the monstrous theory, that the axis of the earth had a different inclination formerly from what it has at present; but where in Nature have we any evidence of such gigantic change—a change which would involve in its influence not merely our globe and its satellite, but all our solar system? Let us, then, see if it is necessary to overstep the bounds of reason to explain this problem. That coal could not at present be formed in those regions is self-evident. In that primeval age there must have been more light, and especially more heat thereto.

What is the great equaliser of the temperature of the earth at the present day? No doubt the air has much to do with the climate. No doubt it is the hot sirocco-breath of the Saharan furnace, tempered by great draughts from the Mediterranean, which gives southern Europe its genial climate, and ripens the Grape on the banks of the Vine-clad Rhine. But is not water a more powerful modifier of the temperature of a country than the air? Is it a curious fact, that if you take a pound of water at 60° Fah., and a pound of lead at 60° Fah., and heat them to 120° Fah., you will find that it has taken about twice as much fuel to bring the water to that temperature as to bring the lead up. Again, if you take these heated bodies, and measure the heat given off during cooling, you will find that the water has given off about twice as much as the lead. The thermometer does not indicate the amount but the degree of heat in a body, and water actually requires twice as much heat as the same weight of lead, to raise it to any given temperature. If you pour on a mass of granite a gill of water, the stone will at once appear wet; but pour a gill of water on a brick fresh from the kiln, and it will all soak into the brick, and, hid away in the interior, will give no token of its presence. The absorbing power of the brick is much greater than that of the stone. So it is with water and heat. The Creator has given to water a great power of absorbing heat and hiding it away in its interior. Is it not evident how this property fits it for being the great equaliser of the earth's temperature? It is notorious, that in the winter the sea-coast is not so cold as the inland, whilst in summer it is not so hot. The reason of this is, that the water absorbs the heat of the one season, and gives it off to moderate the cold of the other.

Glance for a moment at a map, and you will see that the gloomy, frozen coast of Labrador—the native home of the seal and the iceberg—is in the same latitude with the fertile England, with its mild climate and busy multitude of men. The great cause of all this difference is the Gulf Stream, that great oceanic river, ever flowing from the Tropics and stranding itself on Northern Europe. It is made up of millions of drops of water, and each sparkling drop is a little casket with its treasure of heat locked up within it. From the fierce burning sun of the tropics it receives it, and hurries away with it to make fertile and inhabitable the western shores of the Old World.

As water is thus the great equaliser of climates, the great distributor of equatorial heat, it is easily seen that if the surface of the globe was almost covered with water, the extremes

of temperature would to a greater or less extent disappear. Now geological facts indicate that in the coal period the greater portion of the earth's surface was covered with water, and that the land which did exist was low and marshy.

The key to unlock the mystery of the existence in high latitudes of the heat requisite to the growth of the coal plants seems to me to be found in this circumstance: The immense mass of water composing the almost universal ocean, was doubtless traversed in all parts by currents similar to the Gulf Stream, but on a still more magnificent scale—and these it was which enabled the coal plants to flourish so near the pole. I have said nothing of the possibility of the crust of the earth having been warmed by the inner fires. This may have contributed somewhat to the growth of the coal flora, but how much, if at all, seems impossible to be judged.

The problem, how the plants received their supply of light, is not so easily solved. It is, however, by no means settled how far plants can endure the absence of light. According to Professor Lyell, Palms flourish under glass in St. Petersburg, lat. 65° N., where the shortest days are only five hours long, and seem scarcely more than a glimmering twilight. How much greater departure from their normal supply of light these plants would endure is not known; but this fact certainly shows that they will bear much greater vicissitudes of light than of heat. Further, many of the living congeners of the carboniferous flora, flourish in the darkest recesses of tropical primeval forests, where no sunbeam ever pierces through the thick foliage, but where a shadowy twilight is alone filtered through the dark screen of living green. If Palms, used to the burning sun of the desert, flourish in lat. 65° N., how much further north can tree Ferns, Club Mosses, &c., native denizens of gloom, exist? And is it not possible that the ancient flora may have had greater powers of enduring the absence of light than the modern allied families?

But there was undoubtedly more light in those northern latitudes formerly than at present. What is coal but carbon? and these millions of tons of carbon have come from plants which must have obtained them directly or indirectly from the atmosphere. Carbon can exist in the air only as carbonic acid. Therefore the atmosphere must have been in that ancient time very largely composed of that gas. Although this gas is so destructive to animals, yet it is a powerful stimulant to vegetation, and its superabundance must have been a great cause of the wondrous, luxuriant profusion of the carboniferous flora.

We know that, owing to the refraction of the atmosphere, the sun is seen by us when actually several degrees below the horizon. Now the refracting power of carbonic acid far exceeds that of either nitrogen and oxygen singly or associated. In a latitude where the sun revolves for days a few degrees below the horizon, it is very evident what an effect this great refracting power must have had on the length of the days and nights. What a very prolonged twilight must have existed there. Taking into consideration these two thoughts—the small supply of light actually necessary to the growth of some plants, and the prolonged twilights produced by the high refracting power of the carbonised atmosphere, is it necessary to imagine that the world has turned a somersault, in order to account for the coal beds of Melville Island?

Although the ocean covered so much of the earth's surface during the carboniferous era, yet coal is not an oceanic deposit. No marine remains are found in it either vegetable or animal. The plants out of which coal is formed must have contained a large proportion of lignin or woody fibre to have yielded so much solid carbon. Now, seaweeds have singularly little of this in them. They are mere pulpy, fleshy masses, which, when dried, are but the shadow of their former selves. On the other hand, the coal could not have been produced in a very dry atmosphere, for the Euphorbias, Cacti, &c., which flourish on dry inland table-lands, are succulent, fleshy plants, composed very largely of watery juices, with but very little solid permanent tissue. Again, when plants die and fall to the ground in an ordinary forest they gradually decay until all that remains of them is a black rich mould. Decomposition or decay is nothing but a slow process of combustion; and, as in that process, if a plentiful supply of air is at hand, continues until not only hydrogen, nitrogen, and other unstable elements are liberated, but the very carbon itself oxidised. To obtain the carbon by slow decay, just as to obtain it by rapid decay—i.e., combustion, only enough oxygen must be present to consume the less resisting, more changeable portions of the wood. The only known method by which this can be done on a large scale in Nature is through the agency of water,

If you examine a log which has lain for years at the bottom of a pond, you will find that, although a similar log on the shore would have crumbled in the same period into mould, yet it is hard and resistant, only blackened by the touch of time. The air has been excluded in great measure from it, and the carbon remains untouched. The Creator has given a constitution to marsh plants, which peculiarly fits them for the formation of coal. They contain a remarkably large amount of woody fibre. Take the soft pliant sphagnum or bog moss, and delicate as it seems, it actually contains a large proportion of lignin—will yield more carbon, pound for pound, than the firm, hard giants of the forest.

It has been shown that coal has been formed under water, and this peculiar constitution of marsh plants would indicate that it had been formed in bogs or marshes, and not at the deltas of rivers. This is confirmed by many circumstances, among which are these two:—First, the fact that so many stumps and even trunks of trees are found standing in an upright condition, apparently just as they grew; second, the immense length and breadth of some of the coal fields, coupled with the circumstance of there having been but so little land in those days, seem strongly to oppose the idea of their formation at the mouth of a river.

It seems certain, upon looking at all sides of the question, that there were immense swamps in the coal ages similar to the famous peat bogs of Ireland and other northern countries, and that it was in them that the depositions of carbon took place. The top of a peat bog is covered over by a luxuriant, living, growing vegetation, whilst underneath is an ever-increasing mass of dead, decaying, vegetable matter. The plants which form by far the larger proportion of each of these are the Mosses.

Upon examining peat taken from near the surface, it will be seen to consist of a matted interwoven mass of stems and roots, blackened by incipient decay, but preserving their form and structure. The further from the surface the more marked is the effect of the slow combustion, till at last a point is reached where the form of the component plants is lost, and the peat is reduced to a black, carbonaceous, spongy mass. Now this material needs only heat and pressure to form it into coal. It has actually been dug out, dried, exposed to a great pressure and heat, and an artificial coal thus been made.

As impressions and even parts of individual plants are found scattered through the coal, so even in the fully-formed peat portions of many species of plants exist. The Moss, however, never retains its structure or form, but is converted into the black, uniform, carbonaceous mass, which constitutes by far the greater part of the peat. No traces of Mosses have as yet been found in the coal. Does it follow from this that they did not exist in the carboniferous era? Much of the coal when examined by the microscope does not exhibit any definite structure; and is it not very probable that it corresponds to the structureless portion of the peat in origin as well as constitution, and that Mosses flourished abundantly in that ancient flora?

The plants that have written their history most profusely on the coal and surrounding shales are the Ferns. Everywhere are their traces visible. Sometimes a single frond, nicely smoothed out as though pressed for an herbarium; again, great piles of them, the fronds crossing, recrossing, and intermingling with one another in endless confusion. Although, as has just been indicated, the abundance of structural *relics* is an index rather of the indestructibility of the plant than its pristine profusion, yet it cannot be doubted that the Filices held a very prominent place in the coal flora: their appearance must have been very similar to the tropical Ferns of the present day. There are found imbedded in the coal huge trunks which have their surface fretted with very large, more or less semi-lunar scars. By means of the microscope, Messrs. Lindley and Hutton have been enabled to demonstrate that these were the trunks of immense tree Ferns. The ordinary frondose Ferns were apparently much the more abundant then, as now.

Mr. Corda, some years since, described some peculiar *relics*, which he called Psaronius. These are very abundant in some localities; they are always in the form of a short thick stump, with a thick hard bark, whose surface is covered with a dense mass of rootlets. These, according to Professor Lesquereux resemble, both in external form and internal structure, the short rootstocks of some of the immense Ferns of the island of Java.

The study of fossil Ferns is environed with almost insur-

mountable difficulties. Very rarely is the fructification sufficiently well preserved for any characters to be drawn from it. In the hundreds of specimens which I have examined, there has not been one such. The student is forced back on the form of the fronds, and the distribution of the nervules, both for family, generic, and specific characters. For this reason, there is scarcely another study in natural history so uncertain and unsatisfactory. Different portions of the same plant often belong to different sub-orders.

The most strikingly beautiful of all impressions left on the coal are those made by the *Lepidodendra*. These plants were more closely allied to the *Lycopodiaceæ* or Club Moss family, than to any other living plants. The living representatives of this family do not attain to above a few inches in height, generally trailing on the ground; but not so with the *Lepidodendra* of the coal age. The remains of their trunks are often 20, 30, and 40 or even more feet in length, indicating the immense size to which they attained. They must have been a very striking feature of that ancient flora, very probably forming in some places groves themselves, in others mingling with the Conifers and tree Ferns.

All through the coal measures are found in abundance sections of peculiar, long, cylindrical stems. These are remarkable for being articulated, with their joints very close together, and surrounded by a sheath, mostly formed of acute, closely-set teeth. Their surfaces are generally cuniculate, the channels or grooves often alternating at the joints.

These fossils are the *Calamites* of systematists. On account of their external resemblance to the existent *Equisitaceæ* or Horse-tail tribe, they have been considered as allied to them; but recent investigations have revealed more truly and completely their history. The microscopical examination of their stems has shown that they were Conifers; and the discovery of their fructification has confirmed this curious revelation. A peculiar form of vegetable *reliquæ* has long been known to be abundant in the coal measures, especially where the *Calamites* appear to have flourished. They consist of minute stems or branches most generally, but not always, simple, and beset at short intervals with whorls of linear, single-nerved leaves. These leaves resemble more nearly the awl-shaped foliage of our Pines than that of any other existing plant. Now the perfected fructification of these plants has been discovered. It consists of compressed, apparently monospermous nutlets, which are generally more or less acute, often encircled by a narrow wing, and always situated in the axils of the whorls. The male flowers have also been found. They are terminal ear-like spikes, of appressed scales, enclosed in a mass of united appressed leaf-like bracts. These vegetable remains are the *Asterophyllites* of Brongniart. Various theories have been advanced as to their botanical relations, all founded on the premise that they were distinct, perfect plants; but these have all been disproved by the recent discovery that they are nothing but the branches of the *Calamites*. According to Professor Lesquereux, these *Calamites* were probably annuals, or, at least, short-lived plants, which grew up very rapidly. As they grew, they gave off constantly towards their summits these branches. The individual branches soon died, and were at all times easily detached from the parent stem. In the more perfectly preserved *Calamites* the little scars left by them can still be seen around the joints. These stems probably grew in rich marshes, and very close together, forming, like the Bamboo of India, or our own southern Cane, almost impenetrable brakes. The constantly shed branches and decaying falling stems, covered the surface of the marsh in which they grew, and furnished much carbon to the accumulating peat. Intermingled with the *Asterophyllites* are found vegetable *reliquæ*, somewhat similar in appearance to them, but which are still thought to be the remains of separate plants. I refer to the *Annularias* and *Sphærophyllums*. These are jointed branching stems, with verticillate leaves at the articulations.

The leaves are not so strictly linear as those of the *Asterophyllites*, and are very generally more or less wedge shaped. A good deal of mystery still hangs about their botanical affinities, but Professor Lesquereux considers that they were plants living on the mud; now partially immersed in the water, again running over the surface, much as the existent *Azolla caroliniana*. On the other hand, their fructification has been discovered, and so much resembles that of the *Asterophyllites* as to suggest immediately that they, like the latter, were, merely the branches of some huge coniferous plants.

No plants of higher organisation than the Conifers have as yet been found in the coal measures.

APPLYING SULPHUR TO VINES AND OTHER PLANTS.

I SEND you a rough sketch of my bellows. Any moderately ingenious man can make one. I know this, for I made my own! The nozzle is flattened at the end, presenting a wide, narrow opening, as shown in *figs. 2* and *3*. The only dif-

ference between this and the common bellows, is the small valve marked *a*, the flattened nozzle, and the receptacle *b* for the sulphur and lime. Sulphur alone is liable to clog; mixed with the lime, it is blown in a fine cloud to the distance of several feet, and thoroughly distributed among the foliage of the Vines. The lime also adds apparently to the good effects of sulphur, and if used early, and as often as symptoms of mildew appear, is nearest a specific for the disease of anything I have found.—(GEO. W. CAMPBELL, *Bloomington Nurseries, Chicago* (in *Prairie Farmer*).

NEW BOOK.

A Manual of Weathercasts and Storm Prognostics, or the Signs whereby to Judge of Coming Weather. Compiled by ANDREW STEINMETZ. London: G. Routledge & Sons.

A GOOD compilation is far more valuable than a bad original—by a bad original we mean a book of which the contents are a little novelty diluted with a large quantity of verbiage. This manual is a good compilation, and though there is little in it that cannot be found in Fitzroy and Forster's works, yet the collected information is well condensed and well arranged. We can afford space for but one extract.

"When rain is coming ravens caw, swallows chatter, cats 'wash their faces,' small birds prune themselves and make a show of washing, crows make a great noise in the evening, geese cackle more than usual. The reason is, because these creatures love wet weather, and rejoice at the approach of it. Sheep huddle together at the approach of bad weather, and turn their tails towards its direction. Before a storm at sea the cat scampers about the deck with its tail sticking out like that of certain heraldic lions. Rooks are observed to make a sort of gliding motion, called 'playing at football,' before stormy weather. When pigs carry straw to their styes bad weather may be expected. When leeches kept in water remain low down, settled weather may be relied on; but if they rise to the surface, expect wind or rain. Dogs and cats feel lazy and drowsy at the approach of rain. The reason is, because the air is deficient in oxygen, and the damp depresses the nervous system. Horses neigh, cattle low, and sheep bleat against rain, for the same reason as above—difficulty of breathing, &c.; and human beings yawn and gape in like manner.

"At the approach of rain cats turn their backs to the fire and rub their ears, and some nervous people scratch and rub their heads. This is owing either to the incipient humidity getting between the hair, or the air being surcharged with electricity, both which causes produce the sensation of itching. It is as though we were covered with cobwebs, a feeling which all of us know more or less, but which the cat experiences intensely, its hair being very electrical, which may be easily proved in some cases by rubbing it with the hand, when it 'crackles.' Of course, the cat being a tidy creature, merely rubs its hair to keep it down and smooth, for in this state the hair always tends to get ruffled and erect.

"When birds of long flight, rooks, swallows, and others, hang about the homestead, and fly up and down low, then rain and wind may be expected. The reason is, because the insects which they pursue have taken refuge from the cold upper regions of the air, where the change is beginning, in the warmer air near the earth. They fly low because their food is low.

"In spring time, when magpies fly abroad singly, the weather either is or will soon be stormy; but when both birds are seen together the weather must be mild or will soon become so. Hence it is considered unlucky for anglers to see a single magpie in spring, because it forebodes bad weather for fishing. We need scarcely state, that when only

one bird is seen, the other stays at home to keep the nest warm for the little ones.

"When a strong wind and stormy weather are forthcoming, sea-birds, gulls, &c., hang about the land or over it, sometimes flying inward; the reason is, because the fishes upon which they feed keep deeper at the prospect of the stormy winds that blow; and the consequence is, that the gulls must seek a dinner somewhere else, and resort accordingly to the worms on land; and orions to tell, that sort of weather actually makes the worms uncomfortable in the ground, and they wriggle out to be swallowed up by the gulls. Thus does Nature provide for all her dumb creatures, and has even taught the lapwing to stamp on the ground and so make the worms wriggle out, when it wants its breakfast!

"When the gulls, &c., fly out early, and far to seaward, moderate wind and fair weather may be expected, because, if the weather were not likely to be moderate, they would not expect to find the fishes at the surface of the water.

"The stormy petrels, or Mother Carey's chickens, so ominous to sailors, either forecast a storm or show that one has been raging in the latitude where they appear so mysteriously, as it were "walking on the sea," like St. Peter in the gospel (whence their Italian name, from *Pedro*, "little Peter.") The cause of their appearance is the presence of the marine insects upon which they feed, which are kept on the surface by the agitated waves of the tempest, or the "swell" that precedes it.

"When animals seek sheltered places instead of spreading over their usual range, an unfavourable change of weather is probable, if not certain rain or stormy weather.

"If oxen lie on their right sides, look towards the south, and lick their hoofs; if cows look up in the air, and sniff it ("the cattle also concerning the vapour," Job, xxxvi., 33); if asses bray violently; and if cocks crow at unusual hours; and especially when a hen and chickens crowd into the house, those are sure signs of rain. Cocks are prized in Japan for this reason.

Insects also are very sensible of such changes of weather. Flies cling to the ceiling, or disappear; hornets, wasps, and gnats sting more frequently against wet weather than in fair; spiders are restless and uneasy, and frequently drop from the wall, the moist air getting into their webs and making them heavy. Frogs croak importunately; worms creep out of the ground; moles throw up more than earth usual; beetles and crickets are troublesome and noisy. But the surest sign of rain is given by bees; as soon as rain impends they cease to leave their hives, either remaining in them all day, or else flying only to a short distance.

"Horses stretch out their necks and sniff up the air just before a fall of rain. The fact is, they smell the odour of plants and hay, which moisture tends to disseminate, or prevents from rising above.

"Inanimate creation also sounds the alarm of coming wet or change of weather. Paper, straw, &c., fly about before rain. If, during calm, the smoke from chimneys does not ascend readily, or straight upwards, an unfavourable change is probable, with rain, simply because the air has lost density, and is unable to float up the smoke so readily as when drier and denser.

"Just before rain, flowers smell stronger and sweeter, for the reason before given, the vapours of the air preventing the scented particles of their perfume from ascending, as they would in drier air.

"Precisely for the same reason the cesspools, dunghills, water-closets, &c., give note of their existence before rain.

"Flowers and plants are otherwise good barometers. The Pimpernel, which is a very common flower, shuts itself up extremely close against rainy weather. The Trefoil swells in the stalk against rain, so that it stands up very stiff, but the leaves droop and hang down.

"If the Siberian Sowthistle shuts at night, the ensuing day will be fine; if it opens, it will be cloudy and rainy. If the African Marigold continues shut after seven in the morning, rain is at hand. The *Convolvulus arvensis*, the *Calendula fluvialis*, and the *Anagallis arvensis*, or Poor Man's Weather-glass, close on the approach of rain. It is obvious from these facts that we may make a meteorological garden by cultivating these hardy flowers, the observation of which would be a pleasing, and perhaps a profitable occupation."

Mr. Steinmetz does not seem to be aware that *Anagallis arvensis* and the Pimpernel are one and the same.

GARDENING IN CANTERBURY.

I FIND this season that one dozen of Williams's Bon Chrétien Peas will weigh 8½ lbs.; of Summer Bon Chrétien, 7 lbs.; of Flemish Beauty, or Fondante du Bois, 8 lbs.

I find that the leaves of Fruit trees are attacked by the slimy grub, as they are in England.

I send you a dozen Ribston Pippins which have been gathered for one month; and in adding my opinion of their

respective merits, I never saw any equal to them in England for size, colour, and flavour, which says much for the culture of the Ribston Pippin here.—W. SWALE, *Canterbury, New Zealand, March 30th.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Now is a good time to apply salt to Asparagus and Sea-kale beds, about a pound to a square yard is sufficient. It is a great waste to lay it on after the plants have done growing, particularly when the soil is at all inclined to be cold and stiff. Stimulants applied now will enable the roots to lay up a good store of organised matter for another season, and therefore, in addition to salt, occasional applications of liquid manure should be supplied, if possible. The effect of this kind of treatment will be perceived in the autumn by the plants retaining their green colour much longer than others not so treated, and in the spring by increased size and productiveness, showing that the longer the functions of the plants can be preserved by the application of stimulants, the greater the amount of matter that will be stored up for the ensuing season. *Beans*, continue to top them, also *Peas* as they advance, and keep them well gathered as they become fit for table. *Broccoli*, the planting-out of this and *Winter Greens, Kale, Cabbages, and Cauliflowers* must be vigorously prosecuted, and every vacant space should now be kept well filled up. Liquid manure will be in continual request. *Celery*, the trenches for the main crops should now be prepared; for this purpose the spaces between the rows of Peas are very appropriate—the shade from the Peas will be useful to the Celery in its earliest stages, and the Peas will be entirely removed by the time they are likely to be injurious. *Kidney Beans*, another sowing may be made for succession, and advancing crops both of these and *Scarlet Runners* should be well thinned out. Keep the soil around them well forked up and pulverised; continued experience goes far to prove that the fork is the best instrument that can be used amongst widely planted crops. *Peas*, make another sowing; the Early Frame is the best sort for this and the next sowing, after which time there is little chance of their coming to perfection. *Lettuce*, continue to make occasional sowings of the White Silesian for stewing, and the Bath Cos and Green Cos for salads. *Turnips*, keep them well thinned-out, and watered when needful. *Tomatoes*, see that they are well thinned-out and nailed to the walls.

FRUIT GARDEN.

If dry weather set in we would recommend that due attention be given to watering fruit trees in general, for as the fly and other insects are unusually prevalent, an extra exhalation will be the consequence. It is impossible to apply tobacco water in extent commensurate with the evil; clean water can, however, be forcibly dashed on the infested trees, and in such cases it is well to have some fresh-slaked lime at hand with which to cover the ground at the foot of the trees, for unless something is done the insects will re-ascend. To those who are particularly anxious about the future success of their favourite fruits, or who have been planting new kinds, we would say, Make strenuous efforts during the present period to extirpate insects, and to assist weakly or overborne trees. Rest assured that no mode of planting, winter pruning, or complicated modes of training, will be of any avail unless the vegetation of the summer's growth be attended to in due time. Gross shoots, or robbers of all kinds, should be constantly stopped when about 6 inches long throughout the growing season. A very general mulching should now be provided in the fruit garden where trees are properly planted and possess, as they ought to do, an abundance of surface roots. This proceeding is of the utmost importance. It is, moreover, easily accomplished, and when properly carried out, by no means unsightly. Now is the best time to thin out the young canes of Raspberries. Pinch off the tops of the young shoots of Figs, and thin the fruit if too thick. As soon as the Grapes on the open wall are set they should be well thinned; it amply repays the extra trouble.

FLOWER GARDEN.

Preparations should now be made for propagating border varieties of Pinks. Choose a shady situation on the north side of a wall or fence; prepare the ground by adding about 2 inches deep of fine, light, sandy soil, to be gently patted with the back of a spade, and then the pippings are pulled from the old plants and inserted without any further preparation, or

* Before stormy weather the spider draws in the threads of his web to the shortest extent; when these are long the weather will be fine. If he remains inactive rain will follow; if during rain he begins to stir, expect fair weather.

rather pressed into the soil. Afterwards give a gentle watering through a fine rose. See that a good number of Pansy cuttings are put in. Ranunculuses, Tulips, Hyacinths, &c., should now be taken up, and after they are dried stored away in some dry room. In light dry soils many things will be benefited by a thorough soaking of water, especially coniferous plants, most of which make but one growth during the season, and should be encouraged at the proper time when rapid growth is wished. This attention will be especially necessary in the case of young specimens growing on lawns. If Stocks, China Asters, &c., are not already planted-out where they are to flower, take advantage of favourable weather to do so, and attend to them with water, &c., for a few days until they become established. Stir the surface of the soil among the bedding-out stock, which will prevent the growth of weeds and greatly promote the progress of the plants. Let Carnations and Picotees be layered as soon as the shoots are in a proper state for that purpose. They make very useful border flowers, and are much prized in a cut state. See, therefore, that plenty of them are secured for next season. All boundary or other hedges should be clipped forthwith. A little pains taken with the walks at this season will be amply repaid by the air of comfort and pleasure which well-kept walks give to any place. The herbaceous tribes will now require a thorough staking. Do not form the plants like besoms, but use sticks enough—sometimes two or three to a plant. Remember the late Mr. Loudon's directions—"Let no two plants touch, if possible."

GREENHOUSE AND CONSERVATORY.

Many of the popular beauties here being at this period of a somewhat ephemeral character, means must be constantly resorted to in order to insure a constant succession of gaiety until frost set in, when the gap will be filled by Chrysanthemums, Camellias, Chinese Primroses, and several other midwinter flowers. The latter lead the way to the forced flowers of returning spring. Those who keep a sharp eye to such matters will always take care to have a surplus stock in hand after the massing of bedding plants has been completed. Such stock should be most ample—not less, but more than is wanted, in order to provide against gaps in the flower garden, and to supply the various in-door demands. Everything remaining in store pots of the spring propagation should be potted off forthwith, and placed on or plunged in ashes in a sheltered spot—sheltered, we mean, from the wind. Balsams, Cockscombs, and other tender annuals for succession, should receive their last shift before they become potbound, and plenty of the Achimenes family should be potted-off, some in large masses. A lot of the best scarlet and Rollisson's Unique Geraniums should be selected for flowering next winter; these should be grown rapidly and frequently stopped. Towards August they will become rather potbound; they must not, however, be shifted, but merely hardened in a very exposed situation until the end of September, in order to make them very sturdy and short-jointed. A light and warm shelf near the glass will then make them objects of great interest all the ensuing winter. Let the Fuchsia have ample supplies of water, and provide succession stock in case of exhaustion. The early-flowered Pelargoniums, now rather exhausted, should have the bulk of their tops removed, and made into cuttings. The old stools may then be laid on their sides in a shady situation until they break buds half an inch in length, when they must be disrooted and repotted in rather reduced pots. Exhausted Cinerarias may be pnt in an old frame or pit, and fumigated; they may then be cut down, and turned out into a raised bed in the garden. They will there feed and produce an abundance of suckers with a little attention in regard to watering, &c. The Perpetual and Bourbon Roses which have been forced should be placed in a cool situation, with the view of repressing further activity; after a season of rest the soil should be shaken from them, and all decayed roots removed, after which they should be repotted in fresh rich earth, and be removed to the protection of a cold pit, and there plunged.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

If we had time we would prick out separately most of the Winter Greens, Broccolis, &c., as the rains, since we last wrote, have made them large and crowd each other in the seed-beds; but if we cannot do so, we hope ere long to plant out a lot of these and Coleworts. Took advantage of such dripping

weather by transplanting a lot of Turnips where they were rather patchy, and planted some at from 6 to 9 inches apart in beds whence bedding plants had been taken. We have frequently had these doing first-rate, making nice crisp bulbs, and they come in in succession to the bed whence they were thinned. The general idea is that the Swedish Turnip only answers for transplanting-purposes; but we have often proved that the White Dutch and other early kinds answer very well if one precaution is attended to, and that is planting the root, but not burying the young bulb. Very often transplanted Onions make far better, sounder, and larger bulbs than those not transplanted; but in that case, too, the roots, properly speaking, must alone be planted, and the bottom of the future bulb should scarcely go into the ground; just so with these Turnips. So well do all the varieties of the Swedes transplant, that were we sowing a large field we would devote a few poles to a sowing, where the plants could more easily be protected from the fly, and then in a dripping day all vacancies could be filled up. We have seen whole rows thus transplanted, and turn out by far the best in the field. In fact, in the case of some small holdings, we have known the cultivator plant his Swedes just as he planted his own Cabbages; but on a large scale the farmer would be too dependant on the weather to follow such a course.

Asparagus.—Pretty well gave over cutting, as we wish most for forcing next year. What is cut very late is of little use the next season for any purpose. Gave a slight dressing of salt to all, and especially the young rows that will be forced the season after next. This will not only help vigorous growth, but will kill many little weeds that this showery weather is bringing on in abundance.

Sea-kale.—Gave this also a little salt, and would thin some seed-beds if we could. If, however, the plants stand pretty thickly the first season, and are planted-out early next spring in good, rich, rather light soil, and tolerably well cared for during the summer, they will make nice serviceable plants for forcing in the following winter. There is no greater help to the gardener than this delicious vegetable, which may be had with but little trouble from November to the end of May. What has not been forced this season, or rather blanched out of doors by some of the simple modes referred to, will now most likely be in bloom, and what is not wanted for seed had better be cut off, as it greatly exhausts the stool. That head of bloom, just when the flower opens, is most delicious when cooked like any other vegetable. A pinch of carbonate of soda in the water will make it all the more tender, and will injure no one. This is a great help to all green vegetables, and it is more pleasant to see them turned out green and tender as marrow, instead of being of a dingy yellow, half boiled, and pretty well as tough as pieces and ribands of soaked leather. Many cooks holding a high place in their profession consider it beneath them to attend to the boiling of a Cabbage or a Potato, and consequently these vegetables are often sent up to dinner in a state in which even a peasant would not venture to touch them.

Onions.—Will thin them out properly, if possible, before the ground become dry again, they will come out so nicely; and then we shall prick out some thickly on a sandy hard surface, to obtain button Onions, and others we will lay in by the heels neatly to suit for salads, before the last sowing come in. When Onions in a small state, like stocking needles in size, are in demand for salads, seed should be sown in small beds every fortnight up to October, and then early in spring under glass. The worst of the health-keeping Onion is, that it leaves such a scent behind it. For Lettuce, Celery, &c., and general work, see last week.

FRUIT GARDEN.

The fruit of some of the Strawberries out of doors is colouring, and still we have a good supply under glass frames, &c., which is very useful for sending to a distance in this moist weather, as pack how you will, damp fruit, and especially damp Strawberries, travel badly; but though the weather is damp, and there must be plenty of soft food now to be had, the thrushes, blackbirds, and sparrows, are on us in shoals, and no sooner does a berry become red on one side, than it is scooped out like an empty coal-scuttle. Just now the sparrows seem to divide their attention between the Peas and the Strawberries, and their firm strong bills can do fearful execution on both.

The Peach-house and Fig-house we look over almost every day, for though in the former we have placed soft hay on the floor, in case the fruit should fall, a fallen Peach is generally more or less injured, and shows the mark of the fall,

when it lies a day or two, whilst those picked carefully before they are quite ripe, will keep well some days, and always travel better. The very hot days the other week will prevent us gathering in one house for so many weeks as usual, but the bright sun has given a fine colour to the fruit. Thinned out a few of the smaller shoots and leaves from the pretty well untrained Fig plants in the pit, that more light and air should reach the fruit. We believe that often a Fig is scorched into a flavourless thing when exposed fully to the sun, but then the shade of the leaves should not be too dense. On some trees out of doors not touched at all as yet in the way of pruning or regulating, the crop seems to be very heavy, and is swelling fast this moist weather.

Cherries out of doors are changing and becoming soft enough for the birds to be at them, and so must be netted. Have gathered for ten days some nice dishes from the coolest orchard-house, and earlier from the other, which we keep a little closer by shutting it up earlier. We have only had one thrush inside as yet; if birds visit under glass we must net the ventilator-openings.

Cherries are one of the fruits from which great gatherings can be had from pots, and the trees will bear heavily for years, whilst scarcely increasing in size; but they must have plenty of water, and the water must not be stagnant. One or two of our little plants that produced heavily for some years, have shown signs of weakness this season in not setting heavy crops, though the bloom was abundant. For that time the plants have been lifted out of the soil every autumn, breaking any roots through the drainage holes, and then they were well watered, and before winter the surface soil was picked and scraped off and fresh compost added, and this, with the exception of watering, is all the trouble they have occasioned. Once or twice during the summer they are mulched with rotten dung. We would use horse-droppings, but we do not like to be troubled with the corn that grows from them. If we can make the opportunity we have some thought of re-potting all these productive plants in the autumn—that is, to take the ball out, carefully reducing it with a pointed stick or the finger, and to replace it with fresh compost in the same-sized pot; and we would do this if we could as soon as the buds were firm, and the leaves had a good deal of green on them, as we should like the rooting process to go on at once. Merely on account of watering, were we sole regulator in the affair, we should be inclined to plant them out, and keep them within bounds by root-pruning; but for amateurs with little space there can be nothing more simple and pleasing than pot culture, and a small plant will produce nicely in an eight-inch pot, as well in proportion as a larger plant will do in a 14 or 18-inch pot.

Orchard-houses.—Went regularly over the trees in a wet day, greatly thinning the fruit, and most likely leaving too many, this thinning being the best security for carrying Peaches and Nectarines over the stoning without dropping or other signs of distress. Nipped out the points of the shoots, and thinned them so as to let them have a fair amount of sun and air, and to keep down red spider. Washed again with soap water and Gishurst, treated as described the other week. Though after such a regular washing we could with a glass detect scarcely one insect alive, in two or three days we could detect by the same means, when carefully looked for, a few whitish-coloured ones, showing that they had not been long hatched into life. Until the very hot weather about ten days ago, we had scarcely seen a trace of red spider this season, and began to think that for one season it was going to give us no trouble. Its first appearance was in the Peach-house, on a part of a tree that comes quite close to the heating pipes, and which arrangement we cannot alter without pulling the whole old concern to pieces, and then we know it is so rickety that though it may stand if let alone, it will never be fit to put up again. This part of a flat pipe was heavily coated with sulphur, and bricks were placed on it flatwise, also encrusted and lined with sulphur; but, nevertheless, here for the space of a couple of square feet the marked appearance of the leaves told of the enemy, whilst all the rest of the house seemed untouched. This part was all sponged, but that did not quite arrest the insect, though even now there is little appearance of it in the house, and it will be easy to destroy it when the fruit is all gathered. The orchard-house is very near this Peach-house on the same wall, and we have no doubt the insects went from the one place to the other, unless the heat hatched some eggs that all our washings, &c., had left to live on through the winter and spring.

As a proof of how easily such insects may be carried from one house to another, and from one garden to another, we may

repeat what was before stated, that some Strawberry plants in the Peach-house began also to show signs of the visitors, and on watering them on a raised shelf, one of our young men observed something like the finest dots of sand on the sleeve of a light dark coat. These were so small, that with the naked eye we could notice no movement; but when examined through a microscope we could see in motion the tiny limbs of very small, young, white-coloured red spiders. Of course we took out the Strawberry plants carefully and syringed the house where we dared on account of the Peaches, and still the first part of the house affected continues to be the place where more than traces can be seen. When taken in this young state these insects are more easily destroyed, and were it not for the successive broods produced so quickly and in such abundance, it would be no great matter to keep a place free of them where washings can be resorted to. We mention this about the sleeve of the coat to show how easy it is to carry these insects even by our clothes from one place to another, and we do this the more particularly because some friends have been inclined to make merry and joke at a statement of ours, that insects were often taken from one garden to another by the clothes of visitors. We have no doubt that in a nice warm day these young Acari would have lived for hours on the sleeve of the coat, and if the wearer had gone to a garden five or ten miles off, and accidentally brushed against some branches or leaves in the houses so as to dislodge the tiny dots, that there at once they would consider that they had happily come into a rich feeding ground, and would take possession accordingly.

There are a few gardeners who, either on the untidy Mrs. McLarty's principle of "I cannot be fashed," or from the foolish pride that would tempt them to be independent of appearances, make a sort of apologetic boast when they visit another garden—"Oh, I just started as I was," not sensitive enough to perceive the fact that the gardener visited would be ashamed when in their company to meet a respectably-dressed person. A slight regard to our own self-respect—the feeling that enables a working man to plant his foot more firmly on the ground, and bear his head more upright when he is clean and fresh in person and clothing; the respect for our neighbour, that he should not be ashamed of our appearance, whatever company might be with him; aye, and the fact of the insects on working clothes above referred to, ought to induce us when we visit not to go out "as we are;" not by any means as dandies, and gilded popinjays, but clean and respectable in our appearance, and in garments different from those in which we perform our usual work.

Vineries.—We have as yet seen no trace of insects here, though they have never been syringed; but we must not be too confident that they will not come, and yet from the time the fruit has been cleared from each house, they have scarcely been empty of plants, except when the houses were washed. We have just been taking out most things, as little light can now reach them from the roof. In the first division, Sweetwaters are ripening, and some Hamburgs beginning to colour, and from this house we will now clear everything as soon as possible, in order that we may keep the atmosphere drier, and as under-crops in the other succession-houses, we will place Ferns, and fine-leaved Begonias, &c., where enough of light can be obtained for them. The front of such houses with front glass is a capital place for Gloxinias and Gesneras, provided the glass is dulled a little higher than the flowers of the former and the foliage of the latter. Watered the Vines against the back wall of such houses with manure water, and threw some soot and superphosphate on the border out of doors, where the rains would wash them into the border. Proceeded with the first thinning of the late house—a work of great labour amongst so many bunches, though only one bunch was left to a shoot. In order to have a great supply, we have allowed the Vines pretty well to cover the roof, instead of confining them to the rafter, a system which answers that purpose very well as to quantity and weight; but it is much against growing many plants in pots beneath the Vines, after the leaves of the latter keep out so much light from the floor.

ORNAMENTAL DEPARTMENT.

Out of doors the work has chiefly been mowing, sweeping, rolling, weeding, &c., when the weather would admit of it. Potting, tying, and propagating in-doors, especially when wet, such plants as alluded to a fortnight ago. Thinned Hollyhock stems, some for cuttings; planted out half-hardy annuals; sowed hardy annuals for succession, Mignonette for autumn, and in pots for early winter; potted Chrysanthemums, and

cleaned Azaleas. If the dull weather continue must reduce our shade of whitening from plant-houses, or the plants will be too much drawn. Attended to the security of bedding plants in the high winds. Were we to enlarge we would only be repeating the doings of some previous weeks, but we must refer to

Watering, as alluded to last week. Two or three notes have come, which, though without true names, state in so friendly a manner the inability of the writers to appreciate the importance of watering plants out of doors in drizzly weather, whether the weather afterwards should be wet or dry, that we would gladly clear up all these doubts if we could. If they were sure the weather would be dry, it would be all right enough, but why water, when, as the event happened, there have been heavy showers since, and rather dull weather? To this we simply reply, that we were not weather prophet enough to make sure that we should have so much rain; but besides all that, we have ocular demonstration that it was right to water under the circumstances described, whether the succeeding weather in a moderate degree should prove dry or wet. The beds so watered at the roots have gone on nicely, a bright burst of sun did not affect a single leaf. A part unwatered, and chiefly on account of the showers of that and the following day, does not look nearly so well. Though the showers have been heavy, and have wetted the ground considerably, yet they were long in reaching the roots of the fresh-planted plants, and, therefore, there is the fact, that whilst the watered plants have not a single yellow leaf, there is a considerable number of these signs, and proof of a want of reciprocal action between the roots and the branches in the beds of plants that were not so watered, even with the frequent showers up to the time of writing. All these plants were watered separately at planting, but the second watering, as detailed last week, has proved of benefit.—R. F.

COVENT GARDEN MARKET.—JUNE 23.

HEAVY supplies may be noticed in all departments of our trade, and reduced prices in some; but a fair amount of business is now doing. Among our imports is a large cargo of West India Pines, being the first this season. Good samples of Potatoes still come from the Channel Islands, and seem to take the lead in point of quality.

TRADE CATALOGUES RECEIVED.

F. & A. Smith, Park Road, West Dulwich.—Retail Catalogue of New and Choice Plants.

Smith & Simons, 1, Buchanan Street, Glasgow.—Descriptive Priced Catalogue of Dutch and other Flowering Bulbs, New and Select Roses, &c., 1866-7.

George Matthews, Moray Place, Dunedin, New Zealand.—Garden Calendar, and List of Seeds, Trees, Shrubs, &c.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once

N.B.—Many questions must remain unanswered until next week.

"LIVE AND LEARN" will oblige by returning the plants to Gaylard Hadwen, Esq., Birch House, Lees, near Manchester.

BEDDING GERANIUMS.—I must correct an error in my notes on these. I said that Senior Wrangler was exhibited by Mr. Jabez Chater, of Braintree. It should have been of Gonville Nursery, Cambridge.—D., Deal.

TOBACCO-GROWING IN ENGLAND (A Gardener, Winchester).—You will have seen what is stated in our last Number. Legally it cannot be grown at all for gardening-purposes.

PROPAGATING PAULOWNIA IMPERIALIS (C. E., Suffolk).—The readiest way is by layers; the shoots being layered in spring will be well rooted by autumn, and may then be detached from the parent. They are best layered with a tongue. Sometimes suckers come from the root; these, taken off in spring with any root they may have, and potted in sandy loam and peat, strike readily in a gentle heat. Another mode of increasing the plant is by cuttings of the growth of the current year taken off when three parts ripe, or in September, with three or five leaves or joints, cutting them transversely below the lowest joint. After removing the leaves for two-thirds of the length of the cutting, insert the part thus divested of leaves in sandy soil, cover the cuttings with a hand-glass, and keep them close and shaded from bright sun. Their rooting will be hastened by placing them in pots in equal parts of sandy peat, loam, and sand, plunging the pots to the rim in ashes, tan, or sawdust over a gentle hotbed, and affording them the protection of a greenhouse in winter. An equally certain method is, when the shoots have made a growth of 5 or 6 inches, to take them off close to the stem whence they take their rise, and with a sort of heel. This is to be pared smooth with a knife, and the cuttings inserted half their length in the compost previously mentioned, but with their base resting on silver sand, with which, also, they should be surrounded by filling up the pot with it. A mild hotbed of from 70 to 75 is essential, and a moist atmosphere with slight shade from bright sun; care should be taken not to overwater the soil but to keep it just moist. In a month the cuttings will be rooted, or a callosity will be formed; then admit air more freely, and harden off.

VINE CULTURE (T. F.).—You may now apply a dressing of bone dust, and neatly point it in with a fork, but this is best done before the Vines commence growth. The Vines would be all the better of a good syringing at the time of shutting up the house, which we apprehend you do early; and maintaining a moist atmosphere by syringing or sprinkling the floors, walls, &c., twice or thrice a-day is also calculated to promote growth. With the late heavy rains the ground will be sufficiently moist, but you may water the border well if a dry period occur before September. A little Lettuce may be grown on the border, but it will not do the Vines any good. By night the temperature at this season for Vines in active growth should be from 60° to 65°; from 70° to 75° by day in dull and somewhat cloudy weather; and from 75 to 80° on clear days. The temperature may rise to 85° or 90° on hot days with plenty of air.

CLIMBERS FOR CONSERVATORY (W. L.).—Habenorrhannus Abellii, H. aurantiacum, and H. elegans; Mandevilla suaveolens, Rhynchospermum jasmoides, Sollya heterophylla, Passiflora Newmanni, P. coerulea racemosa, and P. Imperatrice Eugenie; Lapageria rosea, Jasminum gracile variegatum, Plumbago capensis, Clematis Jackmanni, Kennedya inophylla florihmda, K. rubicunda superba, Hibbertia Cunninghamii, Bignonia jasmoides, B. grandiflora, Mimosa prostrata, and Erachysemum acuminata.

SAND ON SHELVES—DESTROYING THIRPS (An Old Subscriber).—Common red sand put 3 inches thick on the shelves of a stage will not produce thrips, and it is, as far as we know, not injurious to plants standing upon it in pots. Fine gravel, with the sand or dirt sifted out, is better than sand. A dry atmosphere is the principal cause of the presence of thrips. The best remedy is to have the foliage of the plants dry, to close the house, and on a calm evening to fill the house with tobacco smoke, so that the plants inside the house cannot be seen from the outside. Repeat this fumigation the next night but one, and again in a week twice as before, and do this every week for six weeks. Syringe twice daily, directing the force of the water against the under sides of the leaves, and along with this keep the paths, floors, walls, &c., sprinkled with water twice daily. Syringe and give air early in the morning before the sun shines powerfully upon the house. We fear you do not fumigate sufficiently, and expect one good smoking to kill the insects. That it will do; but no amount of smoking will kill their eggs, and these hatching in a short time give you as many insects as before. If you continue to fill the house with tobacco smoke whenever an insect is seen you will assuredly overcome thrips.

GRAPES COLOURING (M. T.).—Continue watering the greenhouse to secure a moist atmosphere, and admit air very freely. Colour in the berries depends much upon the free circulation of air. We admit it all night in warm weather.

STEAM FROM ZINC TROUGHS (J. F.).—We have had an open tank of zinc and in your found the steam arising from it in any way injurious to the plants in the house, and we have had troughs made of zinc to fit the flow-pipe of ainery, and though we kept them full of water the steam did not in the slightest degree produce any scorching effects on the leaves of the Vines. We can only account for the leaves being scorched by supposing them to have had the moisture from the troughs condensed on them during the night, and the sun shining on the leaves whilst wet would, supposing there was no air, cause scorching. Through straining the pipes on a dull morning to raise steam, and the sun breaking out unexpectedly, we have had leaves scorched when no air was given to allow of the escape of the moisture as it became rapidly heated by the sun's rays, or rather from the atmosphere being saturated with moisture, so that there was no evaporation of the water on the leaves; the water standing on the leaves consequently became so heated as to scorch them.

SLUGS (E. B.).—All that you can do to protect your plants, either in the kitchen garden or flower garden, is to water the surface slightly every evening with lime water. Sprinkling slaked lime among the kitchen garden crops will also keep the slugs in check. As the soil is naturally wet, the only effectual preventives will be draining it, and turning about six inches of the entire surface.

PLANTS EATEN BY CATERPILLARS (G. K. S.).—We think the leaves of the *Calceolarias* and *Verbenas* enclosed are eaten by some caterpillar, which we think you will find if you examine the under side of the leaves minutely. Your only plan will be to have them picked off by hand. Perhaps if you were to look later in the evening than seven o'clock you would be able to find your enemy at work. To the kitchen garden we would advise a dressing of fresh-lacked lime over the whole of the crops, and sprinkling dry soil over those particularly infested. Apply the lime in the evening before dark, but the later the better.

EXCINATION ON BLACK HAMBURG GRAVES (M. A. H.).—The Grape was crushed by the stamping of the post-office officials, so that no excitation could be detected. Probably it arises from the very vigorous growth of the Vines. Admit air more liberally, and keep the roots drier.

SEEDLING CALCEOLARIAS (S. B. E.).—They are pretty, but far inferior in size and form to many others. The colours and marks are not novel.

NAMES OF PLANTS (W. T.). 1, *Chloanthus montana*; 2, *Lauraria cynhalaria*; 3, *Sedum acre*; 4, *Trochium distichum* (*Mrs. M.*); *Callistemon lanceolatus* (*Mr. Alfred*); *Rubus odoratus*. (*Isis*)—*Poa*, uncertain what species. (*L. A.*)—1, *Festucaria ribaria*; 2, *Leucathoe axillaris*, var. (*alter*). *Inoran*—The fragments forwarded to us are insufficient for determining anything more than the family.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 23rd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY AT READING.

It is always agreeable to the feelings to look upon robust old age—old age when the mind is strengthened rather than weakened by time, and the body stands, as stands some ivy-covered Gothic tower, strong as the day it was finished, and far more ornamental. Such was the old age of our Lyndhurst and Palmerston; and not infrequently we clergymen find aged poor whose minds have been in their latter years improved and refined by religion, while their bodies have continued perfectly vigorous. Next to persons, I like to look upon places that are old, but bear no traces of decay. Such, for instance, is Reading, where was buried, in a rich and noble abbey, King Henry I.—a place of mark then, in the twelfth century; and in the time of the civil war Reading was esteemed a place of considerable strength, and the king's garrison which lay nearest to London was here, and 18,000 men—so formidable was Reading—were obliged to carry on the siege by regular approaches, so that it was a town having a large population in the seventeenth century. And now in the latter half of the nineteenth century I find Reading rich, and busy, and increasing, as its new houses for rich and poor, and its new churches, plainly show. So here is an old town vigorous and thriving, extending each year further and further, and holding up its head as importantly as ever among the towns of gravelly, sunny, Thames-bounded Berkshire.

I found the Show at a convenient distance from the station; and although my eye was as yet somewhat filled with Salisbury Show, and therefore almost any such meeting must look small by comparison, yet I soon found that I was present at an exhibition well worthy in all its parts of careful attention. I was among those early ones who were kept waiting outside the gate until the clock struck eleven. It is always pleasant to be early at a show. "The early bird gets the worm," (how foolish of the worm not to go to his bed a little sooner); and one who arrives first is sure to be rewarded with some extra amusement in watching the coming-in of others. Away at once to where those vigorous crows beckon me. I find myself almost alone, save those sleepy-looking guardians of their master's and mistress's fowls, who delight to lol on bundles of straw or sit on empty hampers, and then doze and yawn. Soon come in the exhibitors, breathless, highly excited, as eager to know their fate as ministers after a reform debate. There at

a quick march, almost double quick, come a brace of ladies. An eye-glass is raised, and I hear a loudly expressed "Well done! I have won the first prize. What a triumph! How very nice, dear!" Then the answer from the devoted friend whose vision is clearer—"I don't think those are your birds, dear. The catalogue says they belong to Mr. —." The delighted smile gives place to a look of amazement, that to disappointment, that to despair and depression combined, soon, however, alleviated by a good fit of grumbling, in which the Judge, the Committee, and the other exhibitors are not spared; and ten minutes afterwards self-complacency is entirely restored, and the words, "Won't I beat next time, that's all!" are heard. The poultry tent was of sufficient size; so were the pens, which were not made of wood with wire fronts—not pens, in fact, of the rabbit-hutch type—but the sides were of galvanised iron, and top, back, and front wire. Hence there was a lightness and coolness, for a summer show especially, which was excellent. Then, the middle rows standing back to back, you saw through two pens at once, and the effect was very pleasing, and the Show appeared twice its size. It was the difference between an ugly wooden fence and a division of light iron railings. Away, then, with the wooden rabbit-hutches. Let committees of smaller shows hire these pens. I heard they came from Sheffield. They are light for carriage, and I think take to pieces, and if so, would pack in small compass. Let us everywhere have these, or such-like elegant, durable pens, where no vermin can lurk, and where the means of seeing is so much improved by there being light at the back of the birds.

I found that the Dorkings were here Class A—their right place in my humble opinion, as they, beyond all fowls, are the most useful. It was a strong class, there being fourteen pens, but Captain Lane's was by far the best; the cock is a wonderful bird. The youngest amateur present would as readily have given the first prize to this pen as the Judge, the superiority of the bird was so marked. Miss Milward was second, Mr. Parlett third. The Game class was a good one, especially considering that not one pen came from the north of England, so without such mighty help we could look upon good birds, which was creditable to the south. *Polands*—there were my old black friends from Lyndhurst, and it is encouraging to the few Polish breeders that every one of the four pens was distinguished by prizes or high commendations. Spanish, only three pens present; Mr. Heath's were entered, but did not appear, probably worn out by their week at Salisbury. A week is too long a time for a summer show, but one day is certainly too short for such a show as the Hants and Berks. I forgot to

notice in their order that there were only two pens of Coehins to compete for three prizes! Of the Hamburgs I must say the Silver-pencilled were but indifferent, the Golden the best in both varieties, though one Silver-spangled was good, though deservedly beaten by a very superior Golden pen. There were thirteen pens of Hamburgs in all—not amiss, and so far from the midland counties.

The Brahmas are certainly advancing in favour. Eleven pens here to two of Coehins. It was a case of "the old man being beaten by the boy." Mr. Pares was in his old place with Light Brahmas, and Captain Lane first with his Dark. Among the "variety class," a class which sadly needs dividing, was a good pen of Silver-laced Bantams and a good pen of Malays (Mr. Hinton's); these, I noticed, many fanciers admired. I learnt from a very experienced London gentleman that Malays were formerly, and I believed now, much kept in some of the most confined parts of London, and that in tiny back yards they lived healthily and laid abundantly; so that if I became rector of one of those city churches, and lived near them, I still might keep a few Malays to cheer my eye, and their newly-laid eggs would adorn my breakfast-table. I am glad to speak a word for this variety, as my poultry-conscience tells me I have given it many a hit, and the birds look so very hard at me that I feel it best to keep a respectful distance from the pens. It is certainly something that you can find a fowl which will do well in a state of confinement, which even a Spanish or a Cochin could not stand. So, Malays, you are not handsome I must own; but if useful, and if you give pleasure where no other fowls could do so, long may your long forms be seen in little close back yards. Ducks, Turkeys, Geese, all good and numerous. There were a few Pigeons—too few—and some Rabbits, which gave interest to the Show. The doe with young ones called forth praise from visitors of what our Editors call "the Eve variety."

For the first time in my life I must praise the refreshments. I actually got a decent dinner; not, as at Salisbury, being offered a plate of coarse half-raw beef, a loaf with a bit of soft, wet, unbaked dough in the middle, and when I asked for lettuce, seeing some about, I was told by a facetious or, rather, impudent waiter, "That's a growing, Sir." Though I went for my lunch at two o'clock, when there ought to have been plenty, instead of decent food, I had offered me (I did not eat it), what I know my servant boy would refuse. How long will English people bear to be cheated in this way? for I had first to pay for a lunch ticket. At Reading I found good food and civility, though no grand tent such as at Salisbury.

I never enjoyed any show more than the Hants and Berks, a pleasant, sizeable, nice show it was; jolly farmers with gig umbrellas on their shoulders, kind agricultural faces, high-born ladies, old poultry friends, and a fine, day, not hot, but pleasantly cool, contributed to amuse, please and gratify—WILTSHIRE RECTOR.

EVIL EVENTS AT WOODBRIDGE POULTRY SHOW.

I AM one of the many unfortunates whose fowls arrived too late for competition at Woodbridge; the pecuniary loss to me was about 25s. entrance money, and 7s. 6d. carriage. However, there is a doubt as regards the punctuality of my poultry man, and, perhaps (in my case), the railway company were not to blame, I give them the benefit of the doubt; but there is one little circumstance connected with that Show which I am unable to understand. A beautiful pen of Pile Game Bantams I sent, has never returned, nor can I obtain any information respecting them. The Secretary wrote and told me that a tent was blown down, and that several birds escaped. On inquiring of him for the missing Piles, he has not honoured me with a reply, so I presume the birds have "down away," unless they are being detained at Woodbridge (as a couple of Brahma hens of mine once were), until another exhibition elsewhere be over.

This is not encouraging on the whole, but I am still simple enough to believe that if the fact be mentioned in the columns of "our Journal," it may come under the notice of the holder of the birds, and he may be induced to restore them. I have plenty of their chickens, but I am sure none better than the parents, so I really should like to recover them.—T. C. H.

PREVENTING A HEN SITTING.—Seeing several remedies for sitting hens, I have one which I used when a boy with good

success, making much fun: Take a red rag as large as your two hands, and tie it on to the hen's tail firmly, and let her go; she will not stop to sit. The rag must be very red.—W. L. P.

SPANISH FOWLS PLUCKING EACH OTHER AT THE SALISBURY SHOW.

SEEING in the Journal some remarks by "WILTSHIRE RECTOR" about the first-prize Spanish fowls at the Bath and West of England Show, held at Salisbury, having plucked each other bare, I beg to state that as soon as the judging was over Dr. Brent, the senior Steward, allowed me to remove the hens to empty pens; but they were put back by Mr. Bush, and he gave orders they were not to be removed unless one bird was actually killing the other. The plucking was caused by one of the hens only going to Beverley the previous week, and the other hen being added for the Salisbury Show; and though they had all been previously running together, the temporary separation for Beverley caused it. The refusal of Mr. Bush to allow them to be removed after the judging was over has completely spoiled the pen for months to come.—JOUX MARTIN, Poultry Manager for Viscountess Holmesdale.

THE THORNE AGRICULTURAL AND POULTRY EXHIBITION.

FROM the visitation of rinderpest all agricultural shows of the present season have suffered exceedingly, whilst not a few such meetings have been much assisted this year by the poultry department in carrying out the annual exhibition. We rejoice to say the Thorne Show just closed has been a most successful one, although the positively drenching rains of the two preceding days angred most inauspiciously. The afternoon of the Tuesday was one continuous blinding sheet of rain, and everything foretold a most comfortless meeting; but happily for all parties the Wednesday proved all that the most ardent well-wisher of the Thorne Meeting could desire. It is true that the look of the morning sun was watery in the extreme on Wednesday last, and a soaking day seemed then inevitable. As time went on, however, all things began to brighten; so much so, that the most downcast of the Committee ventured then to hope for better things. About 10 A.M. the weather seemed to settle down for a fine day, and the result proved that such conclusions were the true ones, although an occasional heavy drop or so of rain showed that the atmosphere was still changeable. We cannot dwell on what might have been the consequence of the weather had it continued as it was the day previous to the Show, it must have resulted in an absolute failure, however, as all the Exhibition was thoroughly exposed; but we turn with unfeigned pleasure to the fact, that on the day of the meeting all was summer-like throughout, and every one who attended thoroughly enjoyed this annual re-union.

The Show was remarkably well attended, and the truly indefatigable Secretary, Mr. Richardson, displayed, as usual, his willing attention to every inquirer, and thus obtained not only the continuance of the good wishes of old friends, but equally enlisted the good opinion of those parties who now met that gentleman for the first time. Such a Secretary is indeed the greatest acquisition to any show.

The *Spanish* was one of the best classes on the ground, and the three principal pens of this breed were very close rivals. *Dorkings*, on the contrary, were not nearly so good; the condition of the birds throughout being not by any means perfection. At none of the previous Thorne Shows has there been so small an entry of *Coehins*, and although the winning birds were quite equal, perhaps, to usual, the class was by no means remarkable for excellence. The *Game* classes necessarily (in June) lacked that most important feature "condition;" so much so, that in the class for Whites and Piles the second prize was altogether withheld. Many of the pens of the *Brahmas* were exceedingly good birds, but the matching of the birds was most unfortunate. In the Single Game class there was a very good competition, though the condition was not first-rate. In this class Mr. Valentine, of Littleborough, the exhibitor of pen 498, had tried to impose upon the Arbitrators by two or more feathers of his Game cock's tail being tied on; a first glance easily revealed the deception, as it was done most blunderingly, whoever might be the operator; and these deceptions when attempted certainly require a little more artistic skill than was displayed in this instance. Decidedly the best class in the Show-yard was the one for "A pair of single hens of any breed;" in fact so good were they, that the Arbitrators admitted they scarcely "ever saw a better." The class for single cocks of any variety was scarcely less creditable.

Turkeys and adult *Geese* were well worthy of especial mention, but the gulls—or, as here called, "gibs"—that is, Geese of the current year's hatching, were not so good and matured as would be natural to the midland and southern counties of England. *Guinea Fowls* were excellent.

A poor dog fox, caught only a few days prior to the Show on the Moors, was the very unwilling occupant of a large pen; he appeared to be quite willing, however, to have foregone all public admiration to have gained his natural liberty. We admit that he looked with a longing eye, if not lovingly, on his feathered neighbours, but seemed as though some slight idea flitted occasionally across his mind that the doom of a "bagged Fox" is not one to be too closely sifted or reflected on.

We again repeat our congratulations on the fineness of the weather that prevailed. The thoughts of damp feet seemed never to have entered into the consideration of the fairer portion of the visitors, and the Show of 1866 proved a complete success.

With so highly deserving a Committee, and so indefatigable a Secretary, such a result is most gratifying, and we ourselves earnestly hope, ere another season comes round, the rinderpest may prove a bygone, and the Thorne Meeting may again attain its former proportions.

SPANISH.—First, Messrs. Birch & Boulter, Sheffield. Second, H. Beldon, Bingley. Highly Commended, J. Thresh, Manchester. Commended, W. Harvey Sheffield; F. Marchant, Halifax.

COCHIN-CHINA.—First, C. W. Brierley, Manchester. Second, H. Beldon. **BAHAMA FOOTRA.**—First, G. H. Roberts, Preston. Second, W. Harvey, Donking. —First, W. Harvey. Second, D. White, Driffield.

GAME (White and Piles).—Frize, Messrs. Sales & Bentley, Crowle. **GAME (Black-breasted and other Reds).**—First, E. Akroyd, Bradford. Second, Messrs. Sales and Bentley. Commended, H. Beldon.

GAME (Duckwings, and other Greys and Blues).—First, R. Pashley, Worksop. Second, F. Wright, Sheffield. Commended, Master Cocking, Crowle.

GAME (Any breed).—Cup, C. W. Brierley, Middleton. Second and Extra Second, Messrs. Sales and Bentley.

GAME COCK (Any breed).—Cup, C. W. Brierley. Second, E. Akroyd, Extra Second, R. Pashley, Worksop. Highly Commended, J. D. Newsome, Batley. Messrs. Sales & Bentley.

POLAND (Any variety).—First and Second, H. Beldon. **HAMBURGH (Silver-spangled).**—First, H. Beldon. Second, A. K. Wood, Kendall.

HAMBURGH (Golden-spangled).—First, H. Beldon. Second, A. K. Wood. **HAMBURGH (Silver-pencilled).**—First, A. K. Wood. Second, H. Beldon. **HAMBURGH (Golden-pencilled).**—First, H. Beldon. Second, G. Holmes, Driffield.

ANY FARMYARD CROSS.—First, H. Beldon (Black Hamburgs). Second, Hon. F. C. H. Hawke, Womersley Park (Red Caps).

GAME BANTAMS (Any breed).—Silver Cup and Second, Master G. Crossland, Wakefield. Highly Commended, J. D. Newsome, Batley.

BANTAMS (Silver or Golden-laced).—First, Messrs. S. & R. Ashton, Mottram. Second, T. C. Harrison, Hull.

BANTAMS (Black, White, or any coloured).—First and Second, J. R. Jessop, Hull. Highly Commended, Messrs. J. & A. Briggs, Leeds.

COCK (Any breed).—First, W. Harvey, Sheffield (Buff Cochins). Second, H. Beldon (Golden-spangled Poland). Highly Commended, Messrs. Birch & Boulter, Sheffield (Black Spanish). Commended, Messrs. S. and R. Ashton (Silver-spangled Hamburgs); F. Marchant, Halifax (Black Red Game Bantam).

HENS (Any breed).—First, E. Brown (Spanish). Second, F. Sales, Crowle (Redcaps). Equal Second, W. Harvey (Cochin Bantams). Highly Commended, Messrs. Birch & Boulter (Golden-spangled Hamburgs and Spanish); H. Beldon (Spanish). Commended, G. H. Roberts, Preston (Brahms); S. Slater, Doncaster (Golden-spangled Hamburgs); J. Sledmore, Epworth (Grey Dorkings).

CHICKENS (Any pure breed).—First, W. Wilkinson, Wath (Black Red Game). Second, Messrs. Birch & Boulter (Spanish). Extra Second, C. Spencer, Attleborough, Norfolk (Buff Cochins). Highly Commended, F. Key, Beverley (Grey Dorkings).

GUINEA FOWLS.—First, C. A. Young, Driffield. Second, H. Beldon. Highly Commended, T. C. Harrison, Hull.

TERKEYS.—First, W. Harvey. Second, A. O. Worthington, Newton Park.

GESE.—First, O. A. Young. Second, Mrs. Lee, Thorne. *Gibs.*—First, Mrs. S. Hodgson, Thorne Quay. Second, W. H. Kellitt, Thorne.

DUCKS (Any breed).—First, J. R. Jessop, Hull. Second, T. C. Harrison, Hull.

DUCKS (Aylesbury).—Frize, O. A. Young.

EXTRA STOCK.—Frize, G. Rowskill, Doncaster (Peacock).

PIGEONS.

CARRIERS.—First, J. Thackray, York. Second, H. Yardley, Birmingham. Highly Commended, W. Ashforth, Sheffield; J. Smith, Sheffield.

CROPPERS.—First, J. Thackray. Second, H. Yardley.

TUMBLERS.—First, G. Wostenholm, Sheffield. Second, H. Yardley. Highly Commended, H. Yardley; J. Thackray.

JACOBS.—First, H. Beldon. Second, H. Yardley.

MENS.—First, E. Newbitt, Epworth. Second, G. Pickering, Driffield.

TRUMPETERS.—Frize, F. Key.

TERBLES.—First, H. Yardley. Second, H. Beldon.

FANTALS.—First, H. Yardley. Second, T. C. Newbitt. Highly Commended, F. Key.

OWLS.—First, J. W. Fielding, Rochdale. Second, G. H. Roberts, Preston. Highly Commended, W. Pepper, Sheffield; H. Yardley.

BARBS.—First, H. Beldon. Second, J. Thackray.

The Judges of Poultry were Mr. Edward Hewitt, of Sparkbrook, Birmingham, and Mr. John Douglas, of Clumber, Worksop. Mr. John Crossland, of Wakefield, awarded the Pigeon prizes.

LAY SERMONETTE ON THE BATH AND WEST OF ENGLAND SHOW.

The weather does not come on kindly, but flowers are out, and birds are singing, and chickens are growing, "all a-grow-

ing," and the "WILTSHIRE RECTOR" is, doubtless, like the bees, storing up treats for your readers, amongst the gardens, fields, and woods about Hilltop Rectory. One must, therefore, be jolly, and good-tempered, and thankful, and all that kind of thing in spite of railway charges, and birds delayed and lost. But talking about Wiltshire Rectors and railway directors, brings one gradually in the direction of Salisbury.

They have had a poultry show there, and it was a good one, and they even induced the railway authorities to be liberal in conveying the birds, but I did not avail myself of the opportunity, because the instructions were complex, and my birds were few, but they gave me two prizes, one for each pen that I sent. And why did I send so few? Because it was a long time for birds to be away in hot tents and confined to their baskets or their pens. Many thought as I did; but what was the result? Why the Show ended on Friday at four o'clock, and on Saturday at one o'clock I received my birds, some fifty miles down the Great Eastern, in as good, as bright, and sprightly a condition as when they left me. This ought to have been my text, because it was with this before me that I began to write, and it is this that I want to make known, for it shows a promptitude and care that the managers of other shows would do well to imitate.

Well, they have had not only a poultry show but an agricultural show of no ordinary merit, where, because they could not muster fat beeves in these perilous times, they added the fine arts to field labour, and never was seen such a collection of machinery and agricultural implements. But, the fine arts at an agricultural show! And why not? It may have astonished many of the yokels with things never seen before. All the better. "A little learning is a dangerous thing," and in these days, as men will get all they can for themselves, the more they see and know the better. We have mind among the spindles, and why not among the spades? I want to see it there. "How can he get wisdom that holdeth the plough, and that glorieth in the goad that driveth oxen, and is occupied in their labours, and whose talk is of bullocks?" has been asked of old; but there cannot be harm in trying to impart knowledge, which if not misused is goodly to him that "giveth his mind to make furrows, and is diligent to give the kine fodder." Furrows will not be less straight, nor cattle worse tended from a knowledge of their properties and uses. But farm labourers will misuse knowledge, their masters tell me. I grant it; but how do they use ignorance? My agricultural friends are always more ready to object than to answer, and this question seems to prevent a reply altogether.—EGOMET.

PROFIT FROM DUCKS.

I was particularly struck with a communication signed "B. A.," and headed "Profit from Ducks," in last week's Journal. The writer states that he can keep fourteen Ducks for eight weeks, at a cost of 12s. 1½d. He says the only addition to the food mentioned was the refuse from the house and garden. Surely the said refuse must have been in sufficient quantity to constitute at least half their food, or else there must be a grand mistake in the amount set down for food consumed. Does not he also value the Ducks rather above the market price? as in this part Ducks hatched on March 21st, three weeks earlier than his, are only now worth 2s. 6d. or 3s. at the most.

I will now give my experience in Duck-breeding; and I must say that I found their appetites so voracious, that I am sure 12s. 1½d. would not have kept fourteen of mine more than half the time "B. A." mentions. Mine, like "B. A.'s," were common farmyard Ducks, and were likewise kept shut up. The number of the brood was eight, and they were hatched on the 21st of March. The cost of their keep was as follows:—

	£	s.	d.
Sitting of eggs	0	1	0
Food for hen	0	0	6
Loss of time for ditto	0	0	6
Half bushel of barley meal	0	2	3
3 pecks of middlings	0	1	6
7 lbs. rice	0	0	7
Potatoes	0	0	6
	20	6	10

At five weeks and three days old these eight Ducks were sold for 8s., a fair market price, as other Ducks of the same size were selling in this part; and if my Ducks had not been hatched till April 11th, as "B. A.'s" were, they would not have been worth, at five weeks old, more than 10d. each.

If "B. A.'s" accounts are correct, which my experience makes me think impossible, would he have any objection to give an outline of his management, feeding, and so on—how often the Ducks were fed—the size of the place they were kept in—and how long the hen went with them? If he would do so I have no doubt many of your readers would feel obliged, and none more so than myself; for any one acquainted with a Duck's appetite must have been struck with the small amount put down for food, and the necessarily large balance on the right side in "B. A.'s" communication.—J. R. BERTON.

QUEEN REMOVED WITH A SUPER.

Is removing a super from a stock hive of bees, does it ever happen that the queen is in the super and is removed in the same? How may I distinguish the queen from the workers and drones?

On June 15th, in consequence of my bees having swarmed the day before, I wished to remove the small straw super (Payne's, 8 inches diameter, 7 inches deep), from the stock hive in order to place it on the swarm, intending to leave the box placed between the straw super and the stock hive a few days back, on the stock, as the bees were busy building comb in it. My stock is a common straw hive with a hole in the top, the bees a last year's swarm. I carefully lifted off the super, which seemed very heavy, and placed it on a board with a piece of stick an inch thick under one side, but for a quarter of an hour hardly a bee left. I then turned it up, and found it full of bees. After I set it down again a number of bees, I should think about half, left during the next half-hour; after which I could not induce any more to leave. Again I turned it up, and with a feather tried to brush them out; but they ran down between the combs, and would do anything but leave. After about two hours of this sort of work I thought there must be some reason, and, being a novice, determined to put it back on the stock and apply to you for advice. All this time I had to keep carrying the super about the garden to prevent other bees from entering. The stock hive all this time was as quiet as usual. Can you account for the bees refusing to leave? Do you think the queen was in the super, considering the fact that half the bees or more went home? The inside of the super contained five combs, but they were not joined to the sides anywhere, but only to the top. There was about half an inch between the end of each comb and the straw, so that the bees could pass all round. Is this usual? The two outside combs only seemed to contain honey, and these I took out before returning it to the stock hive. In the three middle combs the cells were much larger; some of them empty, the others covered not with a flat cover, but with a dome-shaped one; some with bees partly protruding. Is this brood? Are supers always so? Can it be prevented?—A NOVICE.

[The queen is sometimes removed with a super, and in this case the fact is generally made evident by the confusion which results in the stock hive as soon as the bees discover their loss. She may be readily distinguished from all others by her being much longer than a worker and less bulky than a drone. A queen might not have been hatched out the day after the issue of a first swarm, or, if hatched, would not be at all likely to be in the super, which was probably not completed, or the combs would have been attached to its sides. The large cells with dome-shaped covers contained drone brood, which is not unusual, but which made the bees reluctant to leave. It need not have been preserved. It is said that the queen may be confined to the stock hive, and breeding in supers entirely prevented by the communication being restricted to narrow slits not exceeding one-fifth of an inch in width. As we have had no experience of this plan, we should be glad if any of our readers who have tried it would report the results.]

REMOVING BEES FROM A WALL.

Which would be the best method of removing and securing in a hive a colony of bees which took possession of a hollow in a garden wall in 1864, and have lived there ever since? The entrance to their abode is 6 feet from the ground, just over a door leading from a garden to an orchard, and so rather an inconvenient place for them to be allowed to continue to hold. The wall is 12 feet high, and very old, so that the bees have had plenty of room to spread between the stones. I was in hopes they would have swarmed, but to the best of my knowledge

they have not done so during the three seasons they have been there, so you may imagine that they are very strong, as they have had it all their own way, no honey having been got from them. If in the evening I opened a hole in the wall, so as to lay bare the bees and combs, and then removed some of the brood combs with the bees on them and fastened them in a flat-topped straw hive, would it be possible to get the remainder of the bees into the hive?—Co. DUBLIN SUBSCRIBER.

[If you can open a hole in the wall sufficient to lay bare the combs, an experienced apiarian would have little difficulty in cutting them out and fitting them into a frame hive, keeping at the same time a bright look-out for and securing the queen. So many unforeseen contingencies are likely to arise, which must be met on the instant, and to combat which the operator must rely on his own resources, that it is difficult, if not altogether impossible, to give precise directions. The middle of a fine day is, however, the best time for performing the operation, which may be much facilitated by the use of just sufficient smoke to intimidate without actually stupifying the bees.]

WEIGHT OF SWARMS.

I HAVE had a second swarm only four days after the first, it weighed 2 lbs. (the first weighed 2½ lbs.). The time between the two swarms seems so short, that I am afraid that what I consider the first swarm was in reality the second, and that the first went away unperceived. Please give me your opinion. I found mine on the following extract from Payne's book:—"The period which usually transpires between the first and second swarms is from nine to thirteen days, between the second and third the time is much shorter."—J. R. BERTON.

[We fear your first swarm must have escaped, and that those which have been secured are really the second and third. The small weight of the supposed first swarm, taken in conjunction with the fact of one issuing only four days after the other, seems to us tolerably conclusive on the point. "Books" should be substituted for "hives," in our answer to you at page 448.]

CARE NEEDED IN DRIVING BEES.

On the 10th of June my bees, in a common straw hive, were hanging out very thickly, and appeared about to swarm. I took an empty clean hive, and drove them in the open way spoken of in your Journal about two years ago. It was my first experiment with bees, and I found no difficulty in getting them into the new hive. When I had driven as many as I considered sufficient, probably about two-thirds of the stock, I placed the new hive on the floor-board of the old hive in the place which it occupied before, and I set the stock hive on a new floor-board at a distance of about 8 yards. The driven bees appear to be doing very well, and are as busy as possible, but I am not quite satisfied with the appearance of the stock hive. There are very few bees about it, and they do not seem to be at work. They alight on all parts of the floor-board round the hive, and on the hive itself, but not many seem to be going in and out. I observe, also, a good many dead bees on the ground beneath the stock hive. I am in doubt what to do, whether or not it would be advisable to place the old hive in its old place again or not.

I must tell you that the stock hive, when I turned it up, seemed quite full of comb, and was very heavy. I did not obtain any honey from it last year, as the bees refused to build in the super, nor did I have a swarm. The reason was, I imagine, because the hive had had a journey last May, and a good many of the bees had died. I had a good superful of honey the year before.

I should be greatly obliged by your advice on two points.

1. As to whether I can do anything to improve the condition of the stock hive?

2. What steps I should take to procure honey this year? Should I super the driven bees? and if so, when? or should I super the old stock? I should be much obliged if you would answer these questions in your Journal, and give me any other hints on the subject. I only have these two hives.—AN AMATEUR, Surrey.

[You have by your manipulation formed a strong swarm, but have in all probability inflicted fatal injury on the stock hive, which when removed to its new position was doubtless

deserted by every bee that could find its way to the old spot. The immature bees which remained behind are likely to fail in raising a queen, whilst they cannot cover or hatch out nearly all the brood, the bulk of which must, therefore, become chilled and abortive. The best and perhaps almost the only remedy is to shake a swarm (a second swarm will do), into the hive, and this should be done with as little delay as possible. Returning the stock hive to its old stand would at this time seriously injure the swarms, and would probably fail in restoring the parent stock. When you had driven two-thirds of the bees the stock hive should have been restored to its place, and the swarm conveyed immediately to a distance of not less than a mile and a half, whence in five or six weeks' time it might be re-transferred to your own apiary. When this temporary removal to a distance cannot be effected, artificial swarming with common hives had better not be attempted unless two stocks are employed, as advised at page 428. You may super the driven bees forthwith, but it would, of course, be useless to put a super on the old stock.]

MANAGEMENT OF SUPERS.

SEEING in your Journal that the bees remaining in a stock hive will not generally fill a super after throwing out a swarm, I am induced to ask your advice as to the following case:—

Hive No. 1 had a box super placed upon it in April, and a glass super upon the box. The glass was filled with honey, and the box with comb, when a swarm left the hive and was lost.

Hive No. 2 had a straw super placed upon it in April, and now seems crowded.

Could I remove the box from No. 1, and place it between the super and stock hive of No. 2? or should I place the super of No. 2 on the top of the box on No. 1, instead of the glass, placing a fresh super on No. 2 to give more room? and must I in either case remove the bees from the different supers before making the alteration?—T. E. BAGGE.

[We should remove the box from No. 1, and place it between the super and stock hive of No. 2. All the bees should be expelled before the box is placed in its new position.]

SPARROWS EATING LIVE BEES.

REFERRING you to my last communication under this head (page 411), I certainly thought that I should not again have had to complain of my quondam friends the sparrows annoying my bees, but I was mistaken. On Sunday last (June 17th), I again saw the sparrows doing exactly the same thing under my hives, notwithstanding that I had provided myself with what is called a "bird-scarer," in the shape of a zinc cat suspended to an iron rod, and swinging with the wind. There were plenty of dead bees lying about, as I had only two days before taken off a box of honey weighing 28 lbs., and in doing so had to destroy about a hundred bees; but live game alone would satisfy these harpies, and they were deliberately again jumping up at the laden bees as they came home, and after considerable pounding of the bodies carrying them off to their nests. Again the mandate went forth, and the next morning my man destroyed no less than than thirty-eight young sparrows and twenty eggs in different nests round my premises!

I should like to know if any other apiarian has been troubled this year in a similar manner? and I say *this* year, because, as I never before noticed such a foray, I cannot help thinking it must be something peculiar to the season. One nest alone, just over my dining-room window, was spared, as the inmates were a worthy couple not guilty of apicide, I having carefully watched them feeding their young with moths and caterpillars.—A BLACKHEATHEN.

BEE SUPERSTITION.

A CORRESPONDENT of one of the New Zealand papers gives the following story as being told by a Buckinghamshire keeper. He relates as follows:—

"Superstitions Indulged in with Regard to Bees.—These are many and curious. I remember when I lived in Buckinghamshire, and kept bees there, noting some strange beliefs respecting them. One evening I was stopping at the house of a farmer, whose mother had died that morning. His wife went out in the evening, and tapped at every hive, repeating before

each, 'Bees, bees, your mistress is dead;' and she gravely assured me that if she had not done so the bees would inevitably have forsaken the spot. One day a difficulty occurred between myself and my gardener in respect to the bees. He wanted to have his way in reference to some arrangements for them, and I had rather a desire to have mine, and we had a little difference on the subject which I cut short by ordering my wishes to be promptly attended to; whereupon the fellow went half-snivelling, half-sulkily away, saying, 'The bees will all die, they'll all die, because there's been words about them.' Now, as I did not wish his words to come true, I took the liberty of smoking my last weed at night up and down the garden walk by which the bees stood, and by a curious coincidence, the gardener came prowling round there, and was rather surprised at finding me out at that time. The same thing happened the next night; and finding that I did not mean to permit an epidemic amongst the bees if I could avoid it, he did not come again, and my bees did not die after all. If I had not suspected that the rascal would strive to serve me out, no doubt my bees would have perished, and I should have been requested to believe that it was in consequence of there having been words about them; which, after all, would no doubt, in one sense, have been perfectly true."

LIGURIANS *versus* BLACK BEES.—One of my correspondents writes to me as follows:—"A stock of pure Ligurians in the possession of a clergyman in Essex sent out two very large swarms in May, and a third on the 4th of June. If the season continue favourable this stock will probably increase to seven in one year! such is the enormous fecundity of pure Ligurian queens."—W. J. P., Dover.

CRYSTAL PALACE.—A list of the newly-added specialities to be seen daily would be too long to insert here. A young hippopotamus; a new aviary of owls, eagles, hawks, and other British birds; an exhibition of bees; and a newly-patented incubator for hatching and nursing poultry and game, deserve remark as forming matters of interest and instruction to young persons in what may be regarded as an addition to the thousand and one ordinary—because happily usual—attractions of the Palace.

OUR LETTER BOX.

GAME FOWL (*Black Game*).—We cannot give you the information you seek, for we have only seen the first Number.

HANTS AND BERKS POULTRY SHOW.—We are informed that the first prize for Spanish was awarded to Mr. James Jenner, of Lewes, Sussex, and not to Mr. A. Heath, of Calne.

PIGEON DISEASED (*A. L. Z.*).—The substance taken from your dead hen Trumpeter, is evidently an indurated yolk, which has been retained owing to some injury or disease of the egg-organs.—B. P. BEENT.

PEA AND GUINEA FOWLS' TIME OF INCUBATING.—HEAT OF INCUBATOR (*W. B.*).—Pea Fowls' eggs require twenty-eight days for hatching, and the eggs of Guinea Fowls (Gallinas, as you call them) twenty-eight to thirty days. The temperature of the incubator should be 104.

BEES IN A WOODBURY HIVE (*W. D. A.*).—1. If a swarm fills a Woodbury hive the first season, it is as much as can be expected of it. 2. The union of two swarms in the manner proposed will generally succeed, although a fight is not absolutely impossible. 3. We do not see that you can do anything more to prevent the issue of a swarm.

REARING YOUNG BELLEFINCHES (*Cecil L.*).—A fortnight is a good age to take the young bullfinches from the nest in order to rear them by hand. They are best well feathered, always provided they are not too old to open their mouths. Place them nest and all in a covered basket. The food may be made as follows:—Scald and well wash some rape seed, so as to soften it and remove its pungency. Soak some stale bread, and beat the two into a stiff paste. Feed every two hours, and give as much each time as they will open their mouths for. Australian crows may be fed like magpies, they are almost omnivorous.—R. P. B.

GALVANISED IRON WATER CISTERNS.—Messrs. Motley & Green have sent us copies of several testimonials in favour of these, and they state that they have had long experience of their durability and efficiency, and have never had a complaint about them.

POULTRY MARKET.—JUNE 25.

Our supply gradually increases, and the tendency is rather to a reduction of prices, except in large fowls.
